D.2.49 Reserved SEI message syntax

reserved_sei_message(payloadSize) {	Descriptor
for(i = 0; i < payloadSize; i++)	
reserved_sei_message_payload_byte	b(8)
}	

D.3 SEI payload semantics

D.3.1 General SEI payload semantics

reserved_payload_extension_data shall not be present in bitstreams conforming to this version of this Specification. However, decoders conforming to this version of this Specification shall ignore the presence and value of **reserved_payload_extension_data**. When present, the length, in bits, of **reserved_payload_extension_data** is equal to $8 * \text{payloadSize} - \text{nEarlierBits} - \text{nPayloadZeroBits} - 1$, where **nEarlierBits** is the number of bits in the **sei_payload()** syntax structure that precede the **reserved_payload_extension_data** syntax element and **nPayloadZeroBits** is the number of **payload_bit_equal_to_zero** syntax elements at the end of the **sei_payload()** syntax structure.

payload_bit_equal_to_one shall be equal to 1.

payload_bit_equal_to_zero shall be equal to 0.

NOTE 1 – SEI messages with the same value of payloadType are conceptually the same SEI message regardless of whether they are contained in prefix or suffix SEI NAL units.

NOTE 2 – For SEI messages with payloadType in the range of 0 to 47, inclusive, that are specified in this Specification, the payloadType values are aligned with similar SEI messages specified in Rec. ITU-T H.264 | ISO/IEC 14496-10.

The list SingleLayerSeiList is set to consist of the payloadType values 2, 3, 6, 9, 15, 16, 17, 19, 22, 23, 45, 47, 56, 128, 129, 131, 132, 134 to 152, inclusive, 154 to 159, inclusive, 200 to 202, inclusive, and 205.

The list VclAssociatedSeiList is set to consist of the payloadType values 2, 3, 6, 9, 15, 16, 17, 19, 22, 23, 45, 47, 56, 128, 131, 132, 134 to 152, inclusive, 154 to 159, inclusive, 200 to 202, inclusive, and 205.

The list PicUnitRepConSeiList is set to consist of the payloadType values 0, 1, 2, 6, 9, 15, 16, 17, 19, 22, 23, 45, 47, 56, 128, 129, 131, 132, 133, 135 to 152, inclusive, 154 to 159, inclusive, 200 to 202, inclusive, and 205.

NOTE 3 – SingleLayerSeiList consists of the payloadType values of the SEI messages specified in Annex D excluding 0 (buffering period), 1 (picture timing), 4 (user data registered by Recommendation ITU-T T.35), 5 (user data unregistered), 130 (decoding unit information) and 133 (scalable nesting). VclAssociatedSeiList consists of the payloadType values of the SEI messages that, when non-scalable-nested and contained in an SEI NAL unit, infer constraints on the NAL unit header of the SEI NAL unit on the basis of the NAL unit header of the associated VCL NAL unit. PicUnitRepConSeiList consists of the payloadType values of the SEI messages that are subject to the restriction on 8 repetitions per picture unit.

The semantics and persistence scope for each SEI message are specified in the semantics specification for each particular SEI message.

NOTE 4 – Persistence information for SEI messages is informatively summarized in Table D.1.

Table D.1 – Persistence scope of SEI messages (informative)

SEI message	Persistence scope
Buffering period	The remainder of the bitstream
Picture timing	The access unit containing the SEI message
Pan-scan rectangle	Specified by the syntax of the SEI message
Filler payload	The access unit containing the SEI message
User data registered by Rec. ITU-T T.35	Unspecified
User data unregistered	Unspecified
Recovery point	Specified by the syntax of the SEI message
Scene information	The access unit containing the SEI message and up to but not including the next access unit, in decoding order, that contains a scene information SEI message or starts a new CLVS
Picture snapshot	The access unit containing the SEI message
Progressive refinement segment start	Specified by the syntax of the SEI message
Progressive refinement segment end	The access unit containing the SEI message
Film grain characteristics	Specified by the syntax of the SEI message
Post-filter hint	The access unit containing the SEI message
Tone mapping information	Specified by the syntax of the SEI message
Frame packing arrangement	Specified by the syntax of the SEI message
Display orientation	Specified by the syntax of the SEI message
Green metadata	Specified by the syntax of the SEI message
Structure of pictures information	The set of pictures in the coded layer-wise video sequence (CLVS) that correspond to entries listed in the SEI message
Decoded picture hash	The access unit containing the SEI message
Active parameter sets	The CVS containing the SEI message
Decoding unit information	The decoding unit containing the SEI message
Temporal sub-layer zero index	The access unit containing the SEI message
Scalable nesting	Depending on the scalable-nested SEI messages. Each scalable-nested SEI message has the same persistence scope as if the SEI message was not scalable-nested

Table D.1 – Persistence scope of SEI messages (informative)

SEI message	Persistence scope
Region refresh information	The set of VCL NAL units within the access unit starting from the VCL NAL unit following the SEI message up to but not including the VCL NAL unit following the next SEI NAL unit containing a region refresh information SEI message (if any)
No display	The access unit containing the SEI message
Time code	The access unit containing the SEI message
Mastering display colour volume	The CLVS containing the SEI message
Segmented rectangular frame packing arrangement	Specified by the syntax of the SEI message
Temporal motion-constrained tile sets	The access unit containing the SEI message and up to but not including the next access unit, in decoding order, that contains an SEI message of the same type or starts a new CLVS
Chroma resampling filter hint	The CLVS containing the SEI message
Knee function information	Specified by the syntax of the SEI message
Colour remapping information	Specified by the syntax of the SEI message
Deinterlaced field identification	One or more pictures associated with the access unit containing the SEI message
Content light level information	The CLVS containing the SEI message
Dependent random access point indication	The access unit containing the SEI message
Coded region completion	The current slice segment associated with the SEI message
Alternative transfer characteristics	The CLVS containing the SEI message
Ambient viewing environment	The CLVS containing the SEI message
Content colour volume	Specified by the syntax of the SEI message
Equirectangular projection	Specified by the syntax of the SEI message
Cubemap projection	Specified by the syntax of the SEI message
Fisheye video information	Specified by the syntax of the SEI message
Sphere rotation	Specified by the syntax of the SEI message
Region-wise packing	Specified by the syntax of the SEI message
Omnidirectional viewport	Specified by the syntax of the SEI message
Regional nesting	Depending on the region-nested SEI messages; each region-nested SEI message has the same persistence scope as if the SEI message was non-region-nested
Motion-constrained tile sets extraction information sets	The access unit containing the SEI message and up to but not including the next access unit, in decoding order, that contains an SEI message of the same type or starts a new CLVS
Motion-constrained tile sets extraction information nesting	The access unit containing the SEI message
SEI manifest	The CVS containing the SEI message
SEI prefix indication	The CVS containing the SEI message
Annotated regions	Specified by the syntax of the SEI message
Shutter interval information	The CLVS containing the SEI message

The values of some SEI message syntax elements, including `pan_scan_rect_id`, `scene_id`, `second_scene_id`, `snapshot_id`, `progressive_refinement_id`, `tone_map_id`, `frame_packing_arrangement_id`, `mcts_id[i]`, `knee_function_id`, `colour_remap_id`, `ilcts_id[i]`, and `regional_nesting_id`, are split into two sets of value ranges, where the first set is specified as "may be used as determined by the application", and the second set is specified as "reserved for future use by ITU-T |

ISO/IEC". Applications should be cautious of potential "collisions" of the interpretation for values of these syntax elements belonging to the first set of value ranges. Since different applications might use these IDs having values in the first set of value ranges for different purposes, particular care should be exercised in the design of encoders that generate SEI messages with these IDs having values in the first set of value ranges, and in the design of decoders that interpret SEI messages with these IDs. This Specification does not define any management for these values. These IDs having values in the first set of value ranges might only be suitable for use in contexts in which "collisions" of usage (i.e., different definitions of the syntax and semantics of an SEI message with one of these IDs having the same value in the first set of value ranges) are unimportant, or not possible, or are managed – e.g., defined or managed in the controlling application or transport specification, or by controlling the environment in which bitstreams are distributed.

It is a requirement of bitstream conformance that when a prefix SEI message with payloadType equal to 17 (progressive refinement segment end) or 22 (post-filter hint) is present in an access unit, a suffix SEI message with the same value of payloadType shall not be present in the same access unit.

It is a requirement of bitstream conformance that the following restrictions apply on containing of SEI messages in SEI NAL units:

- An SEI NAL unit containing an active parameter sets SEI message shall contain only one active parameter sets SEI message and shall not contain any other SEI messages.
- When an SEI NAL unit contains a non-scalable-nested buffering period SEI message, a non-scalable-nested picture timing SEI message, or a non-scalable-nested decoding unit information SEI message, the SEI NAL unit shall not contain any other SEI message with payloadType not equal to 0 (buffering period), 1 (picture timing) or 130 (decoding unit information).
- When an SEI NAL unit contains a scalable-nested buffering period SEI message, a scalable-nested picture timing SEI message, or a scalable-nested decoding unit information SEI message, the SEI NAL unit shall not contain any other SEI message with payloadType not equal to 0 (buffering period), 1 (picture timing), 130 (decoding unit information) or 133 (scalable nesting).

Let prevVclNalUnitInAu of an SEI NAL unit or an SEI message be the preceding VCL NAL unit in decoding order, if any, in the same access unit, and nextVclNalUnitInAu of an SEI NAL unit or an SEI message be the next VCL NAL unit in decoding order, if any, in the same access unit.

It is a requirement of bitstream conformance that the following restrictions apply on decoding order of SEI messages:

- When an SEI NAL unit containing an active parameter sets SEI message is present in an access unit, it shall be the first SEI NAL unit that follows the prevVclNalUnitInAu of the SEI NAL unit and precedes the nextVclNalUnitInAu of the SEI NAL unit.
- When a non-scalable-nested buffering period SEI message is present in an access unit, it shall not follow any other SEI message that follows the prevVclNalUnitInAu of the buffering period SEI message and precedes the nextVclNalUnitInAu of the buffering period SEI message, other than an active parameter sets SEI message.
- When a non-scalable-nested picture timing SEI message is present in an access unit, it shall not follow any other SEI message that follows the prevVclNalUnitInAu of the picture timing SEI message and precedes the nextVclNalUnitInAu of the picture timing SEI message, other than an active parameter sets SEI message or a non-scalable-nested buffering period SEI message.
- When a non-scalable-nested decoding unit information SEI message is present in an access unit, it shall not follow any other SEI message in the same access unit that follows the prevVclNalUnitInAu of the decoding unit information SEI message and precedes the nextVclNalUnitInAu of the decoding unit information SEI message, other than an active parameter sets SEI message, a non-scalable-nested buffering period SEI message, or a non-scalable-nested picture timing SEI message.
- When a scalable-nested buffering period SEI message, a scalable-nested picture timing SEI message, or a scalable-nested decoding unit information SEI message is contained in a scalable nesting SEI message in an access unit, the scalable nesting SEI message shall not follow any other SEI message that follows the prevVclNalUnitInAu of the scalable nesting SEI message and precedes the nextVclNalUnitInAu of the scalable nesting SEI message, other than an active parameter sets SEI message, a non-scalable-nested buffering period SEI message, a non-scalable-nested picture timing SEI message, a non-scalable-nested decoding unit information SEI message, or another scalable nesting SEI message that contains a buffering period SEI message, a picture timing SEI message, or a decoding unit information SEI message.
- When payloadType is equal to 0 (buffering period), 1 (picture timing) or 130 (decoding unit information) for an SEI message, scalable-nested or non-scalable-nested, within the access unit, the SEI NAL unit containing the SEI message shall precede all NAL units of any picture unit that has nuh_layer_id greater than highestAppLayerId, where highestAppLayerId is the greatest value of nuh_layer_id of all the layers in all the operation points that the SEI message applies to.

- When payloadType is equal to any value among VclAssociatedSeiList for an SEI message, scalable-nested or non-scalable-nested, within the access unit, the SEI NAL unit containing the SEI message shall precede all NAL units of any picture unit that has nuh_layer_id greater than highestAppLayerId, where highestAppLayerId is the greatest value of nuh_layer_id of all the layers that the SEI message applies to.

The following applies on the applicable operation points or layers of SEI messages:

- For a non-scalable-nested SEI message, when payloadType is equal to 0 (buffering period) or 130 (decoding unit information), the non-scalable-nested SEI message applies to the operation point that has OpTid equal to the greatest value of nuh_temporal_id_plus1 among all VCL NAL units in the bitstream, has OpLayerIdList containing all values of nuh_layer_id in all VCL units in the bitstream, and has only the base layer as the output layer.
- An SEI message that is directly contained in a scalable nesting SEI message within an SEI NAL unit with nuh_layer_id equal to 0 and has payloadType is equal to 0 (buffering period), 1 (picture timing), or 130 (decoding unit information) applies as specified in Annex C to the layer set as indicated by the scalable nesting SEI message.
- For a non-scalable-nested SEI message, when payloadType is equal to 1 (picture timing), the frame field information carried in the syntax elements pic_struct, source_scan_type and duplicate_flag, when present, in the non-scalable-nested picture timing SEI message applies to the base layer only, while the picture timing information carried in other syntax elements, when present, in the non-scalable-nested picture timing SEI message applies to the operation point that has OpTid equal to the greatest value of nuh_temporal_id_plus1 among all VCL NAL units in the bitstream, has OpLayerIdList containing all values of nuh_layer_id in all VCL units in the bitstream, and has only the base layer as the output layer.
- For a non-scalable-nested SEI message, when payloadType is equal to any value among VclAssociatedSeiList, the non-scalable-nested SEI message applies to the layer for which the VCL NAL units have nuh_layer_id equal to the nuh_layer_id of the SEI NAL unit containing the SEI message.
- An active parameter sets SEI message, which cannot be scalable-nested, applies to all layers in the bitstream.

It is a requirement of bitstream conformance that the following restrictions apply on the values of nuh_layer_id and TemporalId of SEI NAL units:

- When a non-scalable-nested SEI message has payloadType equal to any value among VclAssociatedSeiList, the SEI NAL unit containing the non-scalable-nested SEI message shall have TemporalId equal to the TemporalId of the access unit containing the SEI NAL unit.
- When a non-scalable-nested SEI message has payloadType equal to 0, 1, 129 or 130, the SEI NAL unit containing the non-scalable-nested SEI message shall have nuh_layer_id equal to 0.
- When a non-scalable-nested SEI message has payloadType equal to any value among VclAssociatedSeiList, the SEI NAL unit containing the non-scalable-nested SEI message shall have nuh_layer_id and nuh_temporal_id_plus1 equal to the values of nuh_layer_id and nuh_temporal_id_plus1, respectively, of the VCL NAL unit associated with the SEI NAL unit.

NOTE 4 – For an SEI NAL unit containing a scalable nesting SEI message, the values of TemporalId and nuh_layer_id should be set equal to the lowest value of TemporalId and nuh_layer_id, respectively, of all the sub-layers or operation points the scalable-nested SEI messages apply to unless specified otherwise.

It is a requirement of bitstream conformance that the following restrictions apply on the presence of SEI messages between two VCL NAL units of a picture:

- When there is a prefix SEI message that has payloadType equal to any value among SingleLayerSeiList not equal to 134 (the region refresh information SEI message) or 146 (the coded region completion SEI message), and applies to a picture of a layer layerA present between two VCL NAL units of the picture in decoding order, there shall be a prefix SEI message that is of the same type and applies to the layer layerA in the same access unit preceding the first VCL NAL unit of the picture.
- When there is a suffix SEI message that has payloadType equal to 3 (filler payload), 17 (progressive refinement segment end), 22 (post filter hint) or 132 (decoded picture hash) and applies to a picture of a layer layerA present between two VCL NAL units of the picture in decoding order, there shall be a suffix SEI message that is of the same type and applies to the layer layerA present in the same access unit succeeding the last VCL NAL unit of the picture.

It is a requirement of bitstream conformance that the following restrictions apply on repetition of SEI messages:

- For each of the payloadType values included in PicUnitRepConSeiList, there shall be less than or equal to 8 identical sei_payload() syntax structures within a picture unit.
- There shall be less than or equal to 8 identical sei_payload() syntax structures with payloadType equal to 130 within a decoding unit.

- The number of identical sei_payload() syntax structures with payloadType equal to 134 in a picture unit shall be less than or equal to the number of slice segments in the picture unit.

In the following subclauses of this annex, the following applies:

- The current SEI message refers to the particular SEI message.
- The current access unit refers to the access unit containing the current SEI message.

In the following subclauses of this annex, when a particular SEI message applies to a set of one or more layers (instead of a set of operation points), i.e., when the payloadType value is not equal to one of 0 (buffering period), 1 (picture timing) and 130 (decoding unit information), the following applies:

- The semantics apply independently to each particular layer with nuh_layer_id equal to targetLayerId of the layers to which the particular SEI message applies.
- The current layer refers to the layer with nuh_layer_id equal to targetLayerId.
- The current picture or the current decoded picture refers to the picture with nuh_layer_id equal to targetLayerId (i.e., in the current layer) in the current access unit.

In the following subclauses of this annex, when a particular SEI message applies to a set of one or more operation points (instead of a set of one or more layers), i.e., when the payloadType value is equal to 0 (buffering period), 1 (picture timing) or 130 (decoding unit information), the following applies:

- When the particular SEI message applies to an operation point that does not include the base layer (i.e., when the SEI message is contained in an SEI NAL unit with nuh_layer_id greater than 0), decoders conforming to a profile specified in Annex A and not supporting the INBLD capability specified in Annex F shall ignore that particular SEI message.
- The semantics apply independently to each particular operation point of the set of operation points to which the particular SEI message applies.
- The current operation point refers to the particular operation point.
- The terms "access unit" and "CVS" apply to the bitstream BitstreamToDecode that is the sub-bitstream of the particular operation point.

D.3.2 Buffering period SEI message semantics

A buffering period SEI message provides initial CPB removal delay and initial CPB removal delay offset information for initialization of the HRD at the position of the associated access unit in decoding order.

When the buffering period SEI message is non-scalable-nested or is directly contained in a scalable nesting SEI message within an SEI NAL unit with nuh_layer_id equal to 0 and the current access unit is a CRA or BLA access unit, let skippedPictureList be the list of skipped leading pictures consisting of the RASL pictures associated with the CRA or BLA access unit with which the buffering period SEI message is associated.

When the buffering period SEI message is non-scalable-nested or is directly contained in a scalable nesting SEI message within an SEI NAL unit with nuh_layer_id equal to 0, a picture is said to be a notDiscardablePic picture when the picture has TemporalId equal to 0 and is not a RASL, RADL or SLNR picture.

When the buffering period SEI message is non-scalable-nested or is directly contained in a scalable nesting SEI message within an SEI NAL unit with nuh_layer_id equal to 0, the following applies for the buffering period SEI message syntax and semantics:

- The syntax elements initial_cpb_removal_delay_length_minus1, au_cpb_removal_delay_length_minus1, dpb_output_delay_length_minus1, and sub_pic_hrd_params_present_flag and the variables NalHrdBpPresentFlag and VclHrdBpPresentFlag are found in or derived from syntax elements found in the hrd_parameters() syntax structure that is applicable to at least one of the operation points to which the buffering period SEI message applies.
- The variables CpbSize[i], BitRate[i] and CpbCnt are derived from syntax elements found in the sub_layer_hrd_parameters() syntax structure that is applicable to at least one of the operation points to which the buffering period SEI message applies.
- Any two operation points that the buffering period SEI message applies to having different OpTid values tIdA and tIdB indicate that the values of cpb_cnt_minus1[tIdA] and cpb_cnt_minus1[tIdB] coded in the hrd_parameters() syntax structure(s) applicable to the two operation points are identical.
- Any two operation points that the buffering period SEI message applies to having different OpLayerIdList values layerIdListA and layerIdListB indicate that the values of nal_hrd_parameters_present_flag and vcl_hrd_parameters_present_flag, respectively, for the two hrd_parameters() syntax structures applicable to the two operation points are identical.

- The bitstream (or a part thereof) refers to the bitstream subset (or a part thereof) associated with any of the operation points to which the buffering period SEI message applies.

The presence of buffering period SEI messages for an operation point including the base layer is specified as follows:

- If `NalHrdBpPresentFlag` is equal to 1 or `VclHrdBpPresentFlag` is equal to 1, the following applies for each access unit in the CVS:
 - If the access unit is an IRAP access unit, a buffering period SEI message applicable to the operation point shall be associated with the access unit.
 - Otherwise, if the access unit contains a `notDiscardablePic`, a buffering period SEI message applicable to the operation point may or may not be associated with the access unit.
 - Otherwise, the access unit shall not be associated with a buffering period SEI message applicable to the operation point.
- Otherwise (`NalHrdBpPresentFlag` and `VclHrdBpPresentFlag` are both equal to 0), no access unit in the CVS shall be associated with a buffering period SEI message applicable to the operation point.

NOTE 1 – For some applications, frequent presence of buffering period SEI messages may be desirable (e.g., for random access at an IRAP picture or a non-IRAP picture or for bitstream splicing).

bp_seq_parameter_set_id indicates and shall be equal to the `sps_seq_parameter_set_id` for the SPS that is active for the coded picture associated with the buffering period SEI message. The value of `bp_seq_parameter_set_id` shall be equal to the value of `pps_seq_parameter_set_id` in the PPS referenced by the `slice_pic_parameter_set_id` of the slice segment headers of the coded picture associated with the buffering period SEI message. The value of `bp_seq_parameter_set_id` shall be in the range of 0 to 15, inclusive.

irap_cpb_params_present_flag equal to 1 specifies the presence of the `nal_initial_alt_cpb_removal_delay[i]` and `nal_initial_alt_cpb_removal_offset[i]` or `vcl_initial_alt_cpb_removal_delay[i]` and `vcl_initial_alt_cpb_removal_offset[i]` syntax elements. When not present, the value of `irap_cpb_params_present_flag` is inferred to be equal to 0. When the associated picture is neither a CRA picture nor a BLA picture, the value of `irap_cpb_params_present_flag` shall be equal to 0.

NOTE 2 – The values of `sub_pic_hrd_params_present_flag` and `irap_cpb_params_present_flag` cannot be both equal to 1.

cpb_delay_offset specifies an offset to be used in the derivation of the nominal CPB removal times of access units following, in decoding order, the CRA or BLA access unit associated with the buffering period SEI message when no picture in `skippedPictureList` is present. The syntax element has a length in bits given by `au_cpb_removal_delay_length_minus1 + 1`. When not present, the value of `cpb_delay_offset` is inferred to be equal to 0.

dpb_delay_offset specifies an offset to be used in the derivation of the DPB output times of the CRA or BLA access unit associated with the buffering period SEI message when no picture in `skippedPictureList` is present. The syntax element has a length in bits given by `dpb_output_delay_length_minus1 + 1`. When not present, the value of `dpb_delay_offset` is inferred to be equal to 0.

When the current picture is not the first picture in the bitstream in decoding order, let `prevNonDiscardablePic` be the preceding picture in decoding order with `TemporalId` equal to 0 that is not a RASL, RADL or SLNR picture.

concatenation_flag indicates, when the current picture is not the first picture in the bitstream in decoding order, whether the nominal CPB removal time of the current picture is determined relative to the nominal CPB removal time of the preceding picture with a buffering period SEI message or relative to the nominal CPB removal time of the picture `prevNonDiscardablePic`.

au_cpb_removal_delay_delta_minus1 plus 1, when the current picture is not the first picture in the bitstream in decoding order, specifies a CPB removal delay increment value relative to the nominal CPB removal time of the picture `prevNonDiscardablePic`. This syntax element has a length in bits given by `au_cpb_removal_delay_length_minus1 + 1`.

When the current picture contains a buffering period SEI message and `concatenation_flag` is equal to 0 and the current picture is not the first picture in the bitstream in decoding order, it is a requirement of bitstream conformance that the following constraint applies:

- If the picture `prevNonDiscardablePic` is not associated with a buffering period SEI message, the `au_cpb_removal_delay_minus1` of the current picture shall be equal to the `au_cpb_removal_delay_minus1` of `prevNonDiscardablePic` plus `au_cpb_removal_delay_delta_minus1 + 1`.
- Otherwise, `au_cpb_removal_delay_minus1` shall be equal to `au_cpb_removal_delay_delta_minus1`.

NOTE 3 – When the current picture contains a buffering period SEI message and `concatenation_flag` is equal to 1, the `au_cpb_removal_delay_minus1` for the current picture is not used. The above-specified constraint can, under some circumstances, make it possible to splice bitstreams (that use suitably-designed referencing structures) by simply changing the value of `concatenation_flag` from 0 to 1 in the buffering period SEI message for an IRAP picture at the splicing point. When

concatenation_flag is equal to 0, the above-specified constraint enables the decoder to check whether the constraint is satisfied as a way to detect the loss of the picture prevNonDiscardablePic.

nal_initial_cpb_removal_delay[i] and **nal_initial_alt_cpb_removal_delay[i]** specify the default and the alternative initial CPB removal delays, respectively, for the i-th CPB when the NAL HRD parameters are in use. The syntax elements have a length in bits given by **initial_cpb_removal_delay_length_minus1 + 1**, and are in units of a 90 kHz clock. The values of the syntax elements shall not be equal to 0 and shall be less than or equal to $90\,000 * (\text{CpbSize}[i] \div \text{BitRate}[i])$, the time-equivalent of the CPB size in 90 kHz clock units.

nal_initial_cpb_removal_offset[i] and **nal_initial_alt_cpb_removal_offset[i]** specify the default and the alternative initial CPB removal offsets, respectively, for the i-th CPB when the NAL HRD parameters are in use. The syntax elements have a length in bits given by **initial_cpb_removal_delay_length_minus1 + 1** and are in units of a 90 kHz clock.

Over the entire CVS, the sum of **nal_initial_cpb_removal_delay[i]** and **nal_initial_cpb_removal_offset[i]** shall be constant for each value of i, and the sum of **nal_initial_alt_cpb_removal_delay[i]** and **nal_initial_alt_cpb_removal_offset[i]** shall be constant for each value of i.

vcl_initial_cpb_removal_delay[i] and **vcl_initial_alt_cpb_removal_delay[i]** specify the default and the alternative initial CPB removal delays, respectively, for the i-th CPB when the VCL HRD parameters are in use. The syntax elements have a length in bits given by **initial_cpb_removal_delay_length_minus1 + 1**, and are in units of a 90 kHz clock. The values of the syntax elements shall not be equal to 0 and shall be less than or equal to $90\,000 * (\text{CpbSize}[i] \div \text{BitRate}[i])$, the time-equivalent of the CPB size in 90 kHz clock units.

vcl_initial_cpb_removal_offset[i] and **vcl_initial_alt_cpb_removal_offset[i]** specify the default and the alternative initial CPB removal offsets, respectively, for the i-th CPB when the VCL HRD parameters are in use. The syntax elements have a length in bits given by **initial_cpb_removal_delay_length_minus1 + 1** and are in units of a 90 kHz clock.

Over the entire CVS, the sum of **vcl_initial_cpb_removal_delay[i]** and **vcl_initial_cpb_removal_offset[i]** shall be constant for each value of i, and the sum of **vcl_initial_alt_cpb_removal_delay[i]** and **vcl_initial_alt_cpb_removal_offset[i]** shall be constant for each value of i.

NOTE 4 – Encoders are recommended not to include **irap_cpb_params_present_flag** equal to 1 in buffering period SEI messages associated with a CRA or BLA picture for which at least one of its associated RASL pictures follows one or more of its associated RADL pictures in decoding order.

use_alt_cpb_params_flag may be used to derive the value of **UseAltCpbParamsFlag**. When **irap_cpb_params_present_flag** is equal to 0, **use_alt_cpb_params_flag** shall not be equal to 1. When **use_alt_cpb_params_flag** is not present, it is inferred to be equal to 0.

NOTE 5 – The syntax element **use_alt_cpb_params_flag** may be present in the payload extension of the buffering period SEI message. Decoders conforming to profiles specified in Annex A may ignore this syntax element.

It is a requirement of bitstream conformance that when **use_alt_cpb_params_flag** is present in the buffering period SEI message, the return value of the **more_data_in_payload()** function in the **sei_payload()** syntax structure containing the buffering period SEI message shall be equal to 1.

D.3.3 Picture timing SEI message semantics

The picture timing SEI message provides CPB removal delay and DPB output delay information for the access unit associated with the SEI message.

When the buffering period SEI message is non-scalable-nested or is directly contained in a scalable nesting SEI message within an SEI NAL unit with **nuh_layer_id** equal to 0, the following applies for the picture timing SEI message syntax and semantics:

- The syntax elements **sub_pic_hrd_params_present_flag**, **sub_pic_cpb_params_in_pic_timing_sei_flag**, **au_cpb_removal_delay_length_minus1**, **dpb_output_delay_length_minus1**, **dpb_output_delay_du_length_minus1**, **du_cpb_removal_delay_increment_length_minus1** and the variable **CpbDpbDelaysPresentFlag** are found in or derived from syntax elements found in the **hrd_parameters()** syntax structure that is applicable to at least one of the operation points to which the picture timing SEI message applies.
- The bitstream (or a part thereof) refers to the bitstream subset (or a part thereof) associated with any of the operation points to which the picture timing SEI message applies.

NOTE 1 – The syntax of the picture timing SEI message is dependent on the content of the **hrd_parameters()** syntax structures applicable to the operation points to which the picture timing SEI message applies. These **hrd_parameters()** syntax structures are in either or both of the VPS and the SPS that are active for the coded picture associated with the picture timing SEI message. When the picture timing SEI message is associated with an IRAP access unit with **NoRasOutputFlag** equal to 1, unless it is preceded by an active parameter sets SEI message within the same access unit, the activation of the VPS and the SPS (and, for IRAP pictures with **NoRasOutputFlag** equal to 1 that are not the first picture in the bitstream in decoding order, the determination that the coded picture is an IRAP access unit with **NoRasOutputFlag** equal to 1) does not occur

until the decoding of the first coded slice segment NAL unit of the coded picture. Since the coded slice segment NAL unit of the coded picture follows the picture timing SEI message in NAL unit order, there may be cases in which it is necessary for a decoder to store the RBSP containing the picture timing SEI message until determining the active VPS and the active SPS for the coded picture, and then perform the parsing of the picture timing SEI message.

The presence of picture timing SEI messages for an operation point including the base layer is specified as follows:

- If `frame_field_info_present_flag` is equal to 1 or `CpbDpbDelaysPresentFlag` is equal to 1, a picture timing SEI message applicable to the operation point shall be associated with every access unit in the CVS.
- Otherwise, in the CVS there shall be no access unit that is associated with a picture timing SEI message applicable to the operation point.

When the picture timing SEI message is not scalable-nested or is directly contained in a scalable nesting SEI message within an SEI NAL unit with `nuh_layer_id` equal to 0, the semantics of `pic_struct`, `source_scan_type` and `duplicate_flag` apply to the picture with `nuh_layer_id` equal to 0 and are specified in the following paragraphs.

NOTE 2 – When the picture timing SEI message is directly contained in a scalable nesting SEI message within an SEI NAL unit with `nuh_layer_id` greater than 0 or is contained in a bitstream partition nesting SEI message specified in Annex F, the semantics of `pic_struct`, `source_scan_type` and `duplicate_flag` are specified in Annex F. The frame-field information SEI message specified in Annex F can be used to indicate `pic_struct`, `source_scan_type` and `duplicate_flag` for non-base layers.

pic_struct indicates whether a picture should be displayed as a frame or as one or more fields and, for the display of frames when `fixed_pic_rate_within_cvs_flag` is equal to 1, may indicate a frame doubling or tripling repetition period for displays that use a fixed frame refresh interval equal to `DpbOutputElementalInterval[n]` as given by Equation E-76. The interpretation of `pic_struct` is specified in Table D.2. Values of `pic_struct` that are not listed in Table D.2 are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore reserved values of `pic_struct`.

When present, it is a requirement of bitstream conformance that the value of `pic_struct` shall be constrained such that exactly one of the following conditions is true:

- The value of `pic_struct` is equal to 0, 7 or 8 for all pictures in the CVS.
- The value of `pic_struct` is equal to 1, 2, 9, 10, 11 or 12 for all pictures in the CVS.
- The value of `pic_struct` is equal to 3, 4, 5 or 6 for all pictures in the CVS.

When `fixed_pic_rate_within_cvs_flag` is equal to 1, frame doubling is indicated by `pic_struct` equal to 7, which indicates that the frame should be displayed two times consecutively on displays with a frame refresh interval equal to `DpbOutputElementalInterval[n]` as given by Equation E-76, and frame tripling is indicated by `pic_struct` equal to 8, which indicates that the frame should be displayed three times consecutively on displays with a frame refresh interval equal to `DpbOutputElementalInterval[n]` as given by Equation E-76.

NOTE 3 – Frame doubling can be used to facilitate the display, for example, of 25 Hz progressive-scan video on a 50 Hz progressive-scan display or 30 Hz progressive-scan video on a 60 Hz progressive-scan display. Using frame doubling and frame tripling in alternating combination on every other frame can be used to facilitate the display of 24 Hz progressive-scan video on a 60 Hz progressive-scan display.

The nominal vertical and horizontal sampling locations of samples in top and bottom fields for 4:2:0, 4:2:2 and 4:4:4 chroma formats are shown in Figure D.1, Figure D.2 and Figure D.3, respectively.

Association indicators for fields (`pic_struct` equal to 9 through 12) provide hints to associate fields of complementary parity together as frames. The parity of a field can be top or bottom, and the parity of two fields is considered complementary when the parity of one field is top and the parity of the other field is bottom.

When `frame_field_info_present_flag` is equal to 1, it is a requirement of bitstream conformance that the constraints specified in the third column of Table D.2 shall apply.

NOTE 4 – When `frame_field_info_present_flag` is equal to 0, then in many cases default values may be inferred or indicated by other means. In the absence of other indications of the intended display type of a picture, the decoder should infer the value of `pic_struct` as equal to 0 when `frame_field_info_present_flag` is equal to 0.

source_scan_type equal to 1 indicates that the source scan type of the associated picture should be interpreted as progressive. `source_scan_type` equal to 0 indicates that the source scan type of the associated picture should be interpreted as interlaced. `source_scan_type` equal to 2 indicates that the source scan type of the associated picture is unknown or unspecified. `source_scan_type` equal to 3 is reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders conforming to this version of this Specification shall interpret the value 3 for `source_scan_type` as equivalent to the value 2.

The following applies to the semantics of `source_scan_type`:

- If `general_progressive_source_flag` is equal to 0 and `general_interlaced_source_flag` is equal to 1, the value of `source_scan_type` shall be equal to 0 when present, and should be inferred to be equal to 0 when not present.
- Otherwise, if `general_progressive_source_flag` is equal to 1 and `general_interlaced_source_flag` is equal to 0, the value of `source_scan_type` shall be equal to 1 when present and should be inferred to be equal to 1 when not present.
- Otherwise, when `general_progressive_source_flag` is equal to 0 and `general_interlaced_source_flag` is equal to 0, the value of `source_scan_type` shall be equal to 2 when present and should be inferred to be equal to 2 when not present.

duplicate_flag equal to 1 indicates that the current picture is indicated to be a duplicate of a previous picture in output order. **duplicate_flag** equal to 0 indicates that the current picture is not indicated to be a duplicate of a previous picture in output order.

NOTE 5 – The `duplicate_flag` should be used to mark coded pictures known to have originated from a repetition process such as 3:2 pull-down or other such duplication and picture rate interpolation methods. This flag would commonly be used when a video feed is encoded as a field sequence in a "transport pass-through" fashion, with known duplicate pictures tagged by setting `duplicate_flag` equal to 1.

NOTE 6 – When `field_seq_flag` is equal to 1 and `duplicate_flag` is equal to 1, this should be interpreted as an indication that the access unit contains a duplicated field of the previous field in output order with the same parity as the current field unless a pairing is otherwise indicated by the use of a `pic_struct` value in the range of 9 to 12, inclusive.

Table D.2 – Interpretation of `pic_struct`

Value	Indicated display of picture	Restrictions
0	(progressive) Frame	<code>field_seq_flag</code> shall be equal to 0
1	Top field	<code>field_seq_flag</code> shall be equal to 1
2	Bottom field	<code>field_seq_flag</code> shall be equal to 1
3	Top field, bottom field, in that order	<code>field_seq_flag</code> shall be equal to 0
4	Bottom field, top field, in that order	<code>field_seq_flag</code> shall be equal to 0
5	Top field, bottom field, top field repeated, in that order	<code>field_seq_flag</code> shall be equal to 0
6	Bottom field, top field, bottom field repeated, in that order	<code>field_seq_flag</code> shall be equal to 0
7	Frame doubling	<code>field_seq_flag</code> shall be equal to 0 <code>fixed_pic_rate_within_cvs_flag</code> shall be equal to 1
8	Frame tripling	<code>field_seq_flag</code> shall be equal to 0 <code>fixed_pic_rate_within_cvs_flag</code> shall be equal to 1
9	Top field paired with previous bottom field in output order	<code>field_seq_flag</code> shall be equal to 1
10	Bottom field paired with previous top field in output order	<code>field_seq_flag</code> shall be equal to 1
11	Top field paired with next bottom field in output order	<code>field_seq_flag</code> shall be equal to 1
12	Bottom field paired with next top field in output order	<code>field_seq_flag</code> shall be equal to 1

Figure D.1 – Nominal vertical and horizontal sampling locations of 4:2:0 samples in top and bottom fields

Figure D.2 – Nominal vertical and horizontal sampling locations of 4:2:2 samples in top and bottom fields

Figure D.3 – Nominal vertical and horizontal sampling locations of 4:4:4 samples in top and bottom fields

au_cpb_removal_delay_minus1 plus 1 is used to calculate the number of clock ticks between the nominal CPB removal times of the access unit associated with the picture timing SEI message and the preceding access unit in decoding order

that contained a buffering period SEI message. This value is also used to calculate an earliest possible time of arrival of access unit data into the CPB for the HSS. The syntax element is a fixed length code whose length in bits is given by $\text{au_cpb_removal_delay_length_minus1} + 1$.

NOTE 7 – The value of $\text{au_cpb_removal_delay_length_minus1}$ that determines the length (in bits) of the syntax element $\text{au_cpb_removal_delay_minus1}$ is the value of $\text{au_cpb_removal_delay_length_minus1}$ coded in the VPS or the SPS that is active for the coded picture associated with the picture timing SEI message, although the preceding access unit containing a buffering period SEI message may be an access unit of a different CVS.

The variable BpResetFlag of the current picture is derived as follows:

- If the current picture is associated with a buffering period SEI message that is applicable to at least one of the operation points to which the picture timing SEI message applies, BpResetFlag is set equal to 1.
- Otherwise, BpResetFlag is set equal to 0.

The variables $\text{AuCpbRemovalDelayMsb}$ and $\text{AuCpbRemovalDelayVal}$ of the current picture are derived as follows:

- If the current access unit is the access unit that initializes the HRD, $\text{AuCpbRemovalDelayMsb}$ and $\text{AuCpbRemovalDelayVal}$ are both set equal to 0.
- Otherwise, let the picture $\text{prevNonDiscardablePic}$ be the previous picture in decoding order that has TemporalId equal to 0 that is not a RASL, RADL or SLNR picture, let $\text{prevAuCpbRemovalDelayMinus1}$, $\text{prevAuCpbRemovalDelayMsb}$ and prevBpResetFlag be set equal to the values of $\text{au_cpb_removal_delay_minus1}$, $\text{AuCpbRemovalDelayMsb}$ and BpResetFlag , respectively, for the picture $\text{prevNonDiscardablePic}$, and the following applies:
 - $\text{AuCpbRemovalDelayMsb}$ is derived as follows:

```

if( prevBpResetFlag )
    AuCpbRemovalDelayMsb = 0
else if( au_cpb_removal_delay_minus1 <= prevAuCpbRemovalDelayMinus1 )
    AuCpbRemovalDelayMsb = prevAuCpbRemovalDelayMsb + 2au_cpb_removal_delay_length_minus1 + 1
    (D-1)
else
    AuCpbRemovalDelayMsb = prevAuCpbRemovalDelayMsb

```

- $\text{AuCpbRemovalDelayVal}$ is derived as follows:

$$\text{AuCpbRemovalDelayVal} = \text{AuCpbRemovalDelayMsb} + \text{au_cpb_removal_delay_minus1} + 1$$

(D-2)

The value of $\text{AuCpbRemovalDelayVal}$ shall be in the range of 1 to 2^{32} , inclusive.

pic_dpb_output_delay is used to compute the DPB output time of the picture when SubPicHrdFlag is equal to 0. It specifies how many clock ticks to wait after removal of the last decoding unit in an access unit from the CPB before the decoded picture is output from the DPB.

NOTE 8 – A picture is not removed from the DPB at its output time when it is still marked as "used for short-term reference" or "used for long-term reference".

The length of the syntax element $\text{pic_dpb_output_delay}$ is given in bits by $\text{dpb_output_delay_length_minus1} + 1$. When $\text{sps_max_dec_pic_buffering_minus1}[\text{minTid}]$ is equal to 0, where minTid is the minimum of the OpTid values of all operation points the picture timing SEI message applies to, $\text{pic_dpb_output_delay}$ shall be equal to 0.

The output time derived from the $\text{pic_dpb_output_delay}$ of any picture that is output from an output timing conforming decoder shall precede the output time derived from the $\text{pic_dpb_output_delay}$ of all pictures in any subsequent CVS in decoding order.

The picture output order established by the values of this syntax element shall be the same order as established by the values of PicOrderCntVal .

For pictures that are not output by the "bumping" process because they precede, in decoding order, an IRAP picture with NoRasOutputFlag equal to 1 that has $\text{no_output_of_prior_pics_flag}$ equal to 1 or inferred to be equal to 1, the output times derived from $\text{pic_dpb_output_delay}$ shall be increasing with increasing value of PicOrderCntVal relative to all pictures within the same CVS.

pic_dpb_output_du_delay is used to compute the DPB output time of the picture when SubPicHrdFlag is equal to 1. It specifies how many sub clock ticks to wait after removal of the last decoding unit in an access unit from the CPB before the decoded picture is output from the DPB.

The length of the syntax element `pic_dpb_output_du_delay` is given in bits by `dpb_output_delay_du_length_minus1 + 1`.

The output time derived from the `pic_dpb_output_du_delay` of any picture that is output from an output timing conforming decoder shall precede the output time derived from the `pic_dpb_output_du_delay` of all pictures in any subsequent CVS in decoding order.

The picture output order established by the values of this syntax element shall be the same order as established by the values of `PicOrderCntVal`.

For pictures that are not output by the "bumping" process because they precede, in decoding order, an IRAP picture with `NoRaslOutputFlag` equal to 1 that has `no_output_of_prior_pics_flag` equal to 1 or inferred to be equal to 1, the output times derived from `pic_dpb_output_du_delay` shall be increasing with increasing value of `PicOrderCntVal` relative to all pictures within the same CVS.

For any two pictures in the CVS, the difference between the output times of the two pictures when `SubPicHrdFlag` is equal to 1 shall be identical to the same difference when `SubPicHrdFlag` is equal to 0.

num_decoding_units_minus1 plus 1 specifies the number of decoding units in the access unit the picture timing SEI message is associated with. The value of `num_decoding_units_minus1` shall be in the range of 0 to `PicSizeInCtbsY - 1`, inclusive.

du_common_cpb_removal_delay_flag equal to 1 specifies that the syntax element `du_common_cpb_removal_delay_increment_minus1` is present. `du_common_cpb_removal_delay_flag` equal to 0 specifies that the syntax element `du_common_cpb_removal_delay_increment_minus1` is not present.

du_common_cpb_removal_delay_increment_minus1 plus 1 specifies the duration, in units of clock sub-ticks (see clause E.3.2), between the nominal CPB removal times of any two consecutive decoding units in decoding order in the access unit associated with the picture timing SEI message. This value is also used to calculate an earliest possible time of arrival of decoding unit data into the CPB for the HSS, as specified in Annex C or clause F.13. The syntax element is a fixed length code whose length in bits is given by `du_cpb_removal_delay_increment_length_minus1 + 1`.

num_nalus_in_du_minus1[i] plus 1 specifies the number of NAL units in the *i*-th decoding unit of the access unit the picture timing SEI message is associated with. The value of `num_nalus_in_du_minus1[i]` shall be in the range of 0 to `PicSizeInCtbsY - 1`, inclusive.

The first decoding unit of the access unit consists of the first `num_nalus_in_du_minus1[0] + 1` consecutive NAL units in decoding order in the access unit. The *i*-th (with *i* greater than 0) decoding unit of the access unit consists of the `num_nalus_in_du_minus1[i] + 1` consecutive NAL units immediately following the last NAL unit in the previous decoding unit of the access unit, in decoding order. There shall be at least one VCL NAL unit in each decoding unit. All non-VCL NAL units associated with a VCL NAL unit shall be included in the same decoding unit as the VCL NAL unit.

du_cpb_removal_delay_increment_minus1[i] plus 1 specifies the duration, in units of clock sub-ticks, between the nominal CPB removal times of the (*i* + 1)-th decoding unit and the *i*-th decoding unit, in decoding order, in the access unit associated with the picture timing SEI message. This value is also used to calculate an earliest possible time of arrival of decoding unit data into the CPB for the HSS, as specified in Annex C or clause F.13. The syntax element is a fixed length code whose length in bits is given by `du_cpb_removal_delay_increment_length_minus1 + 1`.

D.3.4 Pan-scan rectangle SEI message semantics

The pan-scan rectangle SEI message syntax elements specify the coordinates of one or more rectangles relative to the conformance cropping window specified by the active SPS. Each coordinate is specified in units of one-sixteenth luma sample spacing relative to the luma sampling grid.

pan_scan_rect_id contains an identifying number that may be used to identify the purpose of the one or more pan-scan rectangles (for example, to identify the one or more rectangles as the area to be shown on a particular display device or as the area that contains a particular actor in the scene). The value of `pan_scan_rect_id` shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of `pan_scan_rect_id` from 0 to 255, inclusive, and from 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of `pan_scan_rect_id` from 256 to 511, inclusive, and from 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `pan_scan_rect_id` in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

pan_scan_rect_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous pan-scan rectangle SEI message in output order that applies to the current layer. `pan_scan_rect_cancel_flag` equal to 0 indicates that pan-scan rectangle information follows.

pan_scan_cnt_minus1 specifies the number of pan-scan rectangles that are specified by the SEI message. `pan_scan_cnt_minus1` shall be in the range of 0 to 2, inclusive.

`pan_scan_cnt_minus1` equal to 0 indicates that a single pan-scan rectangle is specified that applies to the decoded pictures that are within the persistence scope of the current SEI message. When `field_seq_flag` is equal to 1, `pan_scan_cnt_minus1` shall be equal to 0.

`pan_scan_cnt_minus1` equal to 1 indicates that two pan-scan rectangles are specified that apply to the decoded pictures that are within the persistence scope of the current SEI message and that are associated with picture timing SEI messages having `pic_struct` equal to 3 or 4. The first rectangle applies to the first field of a frame in output order and the second rectangle applies to the second field of a frame in output order, where the output order between two fields in one frame is as shown in Table D.2 for `pic_struct` equal to 3 or 4.

`pan_scan_cnt_minus1` equal to 2 indicates that three pan-scan rectangles are specified that apply to the decoded pictures that are within the persistence scope of the current SEI message and that are associated with picture timing SEI messages having `pic_struct` equal to 5 or 6. The first rectangle applies to the first field of the frame in output order, the second rectangle applies to the second field of the frame in output order, and the third rectangle applies to a repetition of the first field as a third field in output order, where the output order of fields in one frame is as shown in Table D.2 for `pic_struct` equal to 5 or 6.

`pan_scan_rect_left_offset[i]`, `pan_scan_rect_right_offset[i]`, `pan_scan_rect_top_offset[i]` and `pan_scan_rect_bottom_offset[i]`, specify, as signed integer quantities in units of one-sixteenth sample spacing relative to the luma sampling grid, the location of the *i*-th pan-scan rectangle. The values of each of these four syntax elements shall be in the range of $-2^{31} + 1$ to $2^{31} - 1$, inclusive.

The pan-scan rectangle is specified, in units of one-sixteenth sample spacing relative to a luma sampling grid, as the region with horizontal coordinates from $16 * \text{SubWidthC} * \text{conf_win_left_offset} + \text{pan_scan_rect_left_offset}[i]$ to $16 * (\text{CtbSizeY} * \text{PicWidthInCtbsY} - \text{SubWidthC} * \text{conf_win_right_offset}) + \text{pan_scan_rect_right_offset}[i] - 1$ and with vertical coordinates from $16 * \text{SubHeightC} * \text{conf_win_top_offset} + \text{pan_scan_rect_top_offset}[i]$ to $16 * (\text{CtbSizeY} * \text{PicHeightInCtbsY} - \text{SubHeightC} * \text{conf_win_bottom_offset}) + \text{pan_scan_rect_bottom_offset}[i] - 1$, inclusive. The value of $16 * \text{SubWidthC} * \text{conf_win_left_offset} + \text{pan_scan_rect_left_offset}[i]$ shall be less than or equal to $16 * (\text{CtbSizeY} * \text{PicWidthInCtbsY} - \text{SubWidthC} * \text{conf_win_right_offset}) + \text{pan_scan_rect_right_offset}[i] - 1$ and the value of $16 * \text{SubHeightC} * \text{conf_win_top_offset} + \text{pan_scan_rect_top_offset}[i]$ shall be less than or equal to $16 * (\text{CtbSizeY} * \text{PicHeightInCtbsY} - \text{SubHeightC} * \text{conf_win_bottom_offset}) + \text{pan_scan_rect_bottom_offset}[i] - 1$.

When the pan-scan rectangular area includes samples outside of the conformance cropping window, the region outside of the conformance cropping window may be filled with synthesized content (such as black video content or neutral grey video content) for display.

`pan_scan_rect_persistence_flag` specifies the persistence of the pan-scan rectangle SEI message for the current layer.

`pan_scan_rect_persistence_flag` equal to 0 specifies that the pan-scan rectangle information applies to the current decoded picture only.

Let `picA` be the current picture. `pan_scan_rect_persistence_flag` equal to 1 specifies that the pan-scan rectangle information persists for the current layer in output order until any of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture `picB` in the current layer in an access unit containing a pan-scan rectangle SEI message with the same value of `pan_scan_rect_id` and applicable to the current layer is output for which `PicOrderCnt(picB)` is greater than `PicOrderCnt(picA)`, where `PicOrderCnt(picB)` and `PicOrderCnt(picA)` are the `PicOrderCntVal` values of `picB` and `picA`, respectively, immediately after the invocation of the decoding process for picture order count for `picB`.

D.3.5 Filler payload SEI message semantics

This SEI message contains a series of `payloadSize` bytes of value 0xFF, which can be discarded.

`ff_byte` shall be a byte having the value 0xFF.

D.3.6 User data registered by Recommendation ITU-T T.35 SEI message semantics

This SEI message contains user data registered as specified in Recommendation ITU-T T.35, the contents of which are not specified in this Specification.

`itu_t_t35_country_code` shall be a byte having a value specified as a country code by Annex A of Recommendation ITU-T T.35.

`itu_t_t35_country_code_extension_byte` shall be a byte having a value specified as a country code by Annex B of Recommendation ITU-T T.35.

`itu_t_t35_payload_byte` shall be a byte containing data registered as specified in Recommendation ITU-T T.35.

The ITU-T T.35 terminal provider code and terminal provider oriented code shall be contained in the first one or more bytes of the `itu_t_t35_payload_byte`, in the format specified by the Administration that issued the terminal provider code. Any remaining `itu_t_t35_payload_byte` data shall be data having syntax and semantics as specified by the entity identified by the ITU-T T.35 country code and terminal provider code.

D.3.7 User data unregistered SEI message semantics

This SEI message contains unregistered user data identified by a universal unique identifier (UUID), the contents of which are not specified in this Specification.

`uuid_iso_iec_11578` shall have a value specified as a UUID according to the procedures of Annex A of ISO/IEC 11578:1996.

`user_data_payload_byte` shall be a byte containing data having syntax and semantics as specified by the UUID generator.

D.3.8 Recovery point SEI message semantics

The recovery point SEI message assists a decoder in determining when the decoding process will produce acceptable pictures for display after the decoder initiates random access or after the encoder indicates a broken link in the CVS. When the decoding process is started with the access unit in decoding order associated with the recovery point SEI message, all decoded pictures at or subsequent to the recovery point in output order specified in this SEI message are indicated to be correct or approximately correct in content. Decoded pictures produced by random access at or before the picture associated with the recovery point SEI message need not be correct in content until the indicated recovery point, and the operation of the decoding process starting at the picture associated with the recovery point SEI message may contain references to pictures unavailable in the decoded picture buffer.

In addition, by use of the `broken_link_flag`, the recovery point SEI message can indicate to the decoder the location of some pictures in the bitstream that can result in serious visual artefacts when displayed, even when the decoding process was begun at the location of a previous IRAP access unit in decoding order.

NOTE 1 – The `broken_link_flag` can be used by encoders to indicate the location of a point after which the decoding process for the decoding of some pictures may cause references to pictures that, though available for use in the decoding process, are not the pictures that were used for reference when the bitstream was originally encoded (e.g., due to a splicing operation performed during the generation of the bitstream).

When random access is performed to start decoding from the access unit associated with the recovery point SEI message, the decoder operates as if the associated picture was the first picture in the bitstream in decoding order, and the variables `prevPicOrderCntLsb` and `prevPicOrderCntMsb` used in derivation of `PicOrderCntVal` are both set equal to 0.

NOTE 2 – When HRD information is present in the bitstream, a buffering period SEI message should be associated with the access unit associated with the recovery point SEI message in order to establish initialization of the HRD buffer model after a random access.

Any SPS or PPS RBSP that is referred to by a picture associated with a recovery point SEI message or by any picture following such a picture in decoding order shall be available to the decoding process prior to its activation, regardless of whether or not the decoding process is started at the beginning of the bitstream or with the access unit, in decoding order, that is associated with the recovery point SEI message.

`recovery_poc_cnt` specifies the recovery point of decoded pictures in output order. If there is a picture `picA` that follows the current picture (i.e., the picture associated with the current SEI message) in decoding order in the CVS and that has `PicOrderCntVal` equal to the `PicOrderCntVal` of the current picture plus the value of `recovery_poc_cnt`, the picture `picA` is referred to as the recovery point picture. Otherwise, the first picture in output order that has `PicOrderCntVal` greater than the `PicOrderCntVal` of the current picture plus the value of `recovery_poc_cnt` is referred to as the recovery point picture. The recovery point picture shall not precede the current picture in decoding order. All decoded pictures in output order are indicated to be correct or approximately correct in content starting at the output order position of the recovery point picture. The value of `recovery_poc_cnt` shall be in the range of $-\text{MaxPicOrderCntLsb} / 2$ to $\text{MaxPicOrderCntLsb} / 2 - 1$, inclusive.

`exact_match_flag` indicates whether decoded pictures at and subsequent to the specified recovery point in output order derived by starting the decoding process at the access unit associated with the recovery point SEI message will be an exact match to the pictures that would be produced by starting the decoding process at the location of a previous IRAP access unit, if any, in the bitstream. The value 0 indicates that the match may not be exact and the value 1 indicates that the match will be exact. When `exact_match_flag` is equal to 1, it is a requirement of bitstream conformance that the decoded pictures at and subsequent to the specified recovery point in output order derived by starting the decoding process at the access unit associated with the recovery point SEI message shall be an exact match to the pictures that would be produced by starting the decoding process at the location of a previous IRAP access unit, if any, in the bitstream.

NOTE 3 – When performing random access, decoders should infer all references to unavailable pictures as references to pictures containing only intra coding blocks and having sample values given by Y equal to $(1 \ll (\text{BitDepth}_Y - 1))$, Cb and Cr both equal to $(1 \ll (\text{BitDepth}_C - 1))$ (mid-level grey), regardless of the value of `exact_match_flag`.

When `exact_match_flag` is equal to 0, the quality of the approximation at the recovery point is chosen by the encoding process and is not specified in this Specification.

broken_link_flag indicates the presence or absence of a broken link in the NAL unit stream at the location of the recovery point SEI message and is assigned further semantics as follows:

- If `broken_link_flag` is equal to 1, pictures produced by starting the decoding process at the location of a previous IRAP access unit may contain undesirable visual artefacts to the extent that decoded pictures at and subsequent to the access unit associated with the recovery point SEI message in decoding order should not be displayed until the specified recovery point in output order.
- Otherwise (`broken_link_flag` is equal to 0), no indication is given regarding any potential presence of visual artefacts.

When the current picture is a BLA picture, the value of `broken_link_flag` shall be equal to 1.

Regardless of the value of the `broken_link_flag`, pictures subsequent to the specified recovery point in output order are specified to be correct or approximately correct in content.

D.3.9 Scene information SEI message semantics

A scene and a scene transition are herein defined as a set of consecutive pictures in output order.

NOTE 1 – Decoded pictures within one scene generally have similar content. The scene information SEI message is used to label pictures with scene identifiers and to indicate scene changes. The message specifies how the source pictures for the labelled pictures were created. The decoder may use the information to select an appropriate algorithm to conceal transmission errors. For example, a specific algorithm may be used to conceal transmission errors that occurred in pictures belonging to a gradual scene transition. Furthermore, the scene information SEI message may be used in a manner determined by the application, such as for indexing the scenes of a video sequence.

A scene information SEI message labels all pictures of the current layer, in decoding order, from the coded picture to which the SEI message is associated (inclusive) to the coded picture to which the next scene information SEI message applicable to the current layer (when present) in decoding order is associated (exclusive) or (otherwise) to the last picture in the CLVS (inclusive). These pictures are herein referred to as the target pictures.

NOTE 2 – The semantics of the scene information SEI message apply layer-wise. However, the scene information SEI message may be contained within a scalable nesting SEI message, which may help in reducing the number of scene information SEI messages, as scene changes and transitions apply across layers.

scene_info_present_flag equal to 0 indicates that the scene or scene transition to which the target pictures belong is unspecified. `scene_info_present_flag` equal to 1 indicates that the target pictures belong to the same scene or scene transition.

prev_scene_id_valid_flag equal to 0 specifies that the `scene_id` value of the picture preceding the first picture of the target pictures in output order is considered unspecified in the semantics of the syntax elements of this SEI message. `prev_scene_id_valid_flag` equal to 1 specifies that the `scene_id` value of the picture preceding the first picture of the target pictures in output order is specified by the previous scene information SEI message in decoding order. When the previous scene information SEI message applicable to the current layer is within the same CLVS as the current scene information SEI message, `prev_scene_id_valid_flag` shall be equal to 1.

NOTE 3 – When a current scene information SEI message is associated with the first picture, in decoding order, of a CLVS, `prev_scene_id_valid_flag` equal to 1 indicates that the `scene_id` values of the current scene information SEI message and the previous scene information SEI message applicable to the current layer in decoding order can be used to conclude whether their target pictures belong to the same scene or to different scenes.

NOTE 4 – When CVS B is concatenated to CVS A and CVS A represents a different scene than the scene CVS B represents, it should be noticed that the `scene_id` value specified for the last picture with a particular `nuh_layer_id` value of CVS A affects the semantics of the scene information SEI message associated with that particular `nuh_layer_id` value and the first picture, in decoding order, of CVS B, when the SEI message is present. Hence, as part of such a concatenation operation, the value of `prev_scene_id_valid_flag` should be set equal to 0 in the scene information SEI message associated with the first picture, in decoding order, of CVS B, when the SEI message is present.

scene_id identifies the scene to which the target pictures belong. When the value of `scene_transition_type` of the target pictures is less than 4, and the previous picture in output order is marked with a value of `scene_transition_type` less than 4, and the value of `scene_id` is the same as the value of `scene_id` of the previous picture in output order, this indicates that the source scene for the target pictures and the source scene for the previous picture (in output order) are considered by the encoder to have been the same scene. When the value of `scene_transition_type` of the target pictures is greater than 3, and the previous picture in output order is marked with a value of `scene_transition_type` less than 4, and the value of `scene_id` is the same as the value of `scene_id` of the previous picture in output order, this indicates that one of the source scenes for the target pictures and the source scene for the previous picture (in output order) are considered by the encoder to have been the same scene. When the value of `scene_id` is not equal to the value of `scene_id` of the previous picture in output order, this indicates that the target pictures and the previous picture (in output order) are considered by the encoder to have been from different source scenes.

The value of scene_id shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of scene_id in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of scene_id in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of scene_id in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

NOTE 5 – When the first picture picA, in decoding order, of the CLVS vidSeqA represents a different scene than the last picture, in output order, of the previous CLVS of the same layer and a scene information SEI message is associated with PicA, the scene_id value of that scene information SEI message should have a random value within the value ranges constrained above. Subsequent scene_id and second_scene_id values may be selected for example by incrementing the initial randomly selected scene_id value. Consequently, when concatenating vidSeqA to a CLVS vidSeqB of the same layer, accidental use of the same scene_id values in vidSeqA and vidSeqB is unlikely.

scene_transition_type specifies in which type of a scene transition (if any) the target pictures are involved. The valid values of scene_transition_type are specified in Table D.3.

Table D.3 – scene_transition_type values

Value	Description
0	No transition
1	Fade to black
2	Fade from black
3	Unspecified transition from or to constant colour
4	Dissolve
5	Wipe
6	Unspecified mixture of two scenes

When scene_transition_type is greater than 3, the target pictures include contents both from the scene labelled by its scene_id and the next scene, in output order, which is labelled by second_scene_id (see below). The term "the current scene" is used to indicate the scene labelled by scene_id. The term "the next scene" is used to indicate the scene labelled by second_scene_id. It is not required for any following picture, in output order, to be labelled with scene_id equal to second_scene_id of the current SEI message.

Scene transition types are specified as follows:

- "No transition" specifies that the target pictures are not involved in a gradual scene transition.
NOTE 6 – When two consecutive pictures in output order have scene_transition_type equal to 0 and different values of scene_id, a scene cut occurred between the two pictures.
- "Fade to black" indicates that the target pictures are part of a sequence of pictures, in output order, involved in a fade to black scene transition, i.e., the luma samples of the scene gradually approach zero and the chroma samples of the scene gradually approach 128.
NOTE 7 – When two pictures are labelled to belong to the same scene transition and their scene_transition_type is "Fade to black", the later one, in output order, is darker than the previous one.
- "Fade from black" indicates that the target pictures are part of a sequence of pictures, in output order, involved in a fade from black scene transition, i.e., the luma samples of the scene gradually diverge from zero and the chroma samples of the scene may gradually diverge from 128.
NOTE 8 – When two pictures are labelled to belong to the same scene transition and their scene_transition_type is "Fade from black", the later one in output order is lighter than the previous one.
- "Dissolve" indicates that the sample values of each target picture (before encoding) were generated by calculating a sum of co-located weighted sample values of a picture from the current scene and a picture from the next scene. The weight of the current scene gradually decreases from full level to zero level, whereas the weight of the next scene gradually increases from zero level to full level. When two pictures are labelled to belong to the same scene transition and their scene_transition_type is "Dissolve", the weight of the current scene for the later one, in output order, is less than the weight of the current scene for the previous one, and the weight of the next scene for the later one, in output order, is greater than the weight of the next scene for the previous one.
- "Wipe" indicates that some of the sample values of each target picture (before encoding) were generated by copying co-located sample values of a picture in the current scene and the remaining sample values of each target picture

(before encoding) were generated by copying co-located sample values of a picture in the next scene. When two pictures are labelled to belong to the same scene transition and their `scene_transition_type` is "Wipe", the number of samples copied from the next scene to the later picture in output order is greater than the number of samples copied from the next scene to the previous picture.

second_scene_id identifies the next scene in the gradual scene transition in which the target pictures are involved. The value of `second_scene_id` shall not be equal to the value of `scene_id`. The value of `second_scene_id` shall not be equal to the value of `scene_id` in the previous picture in output order. When the next picture in output order is marked with a value of `scene_transition_type` less than 4, and the value of `second_scene_id` is the same as the value of `scene_id` of the next picture in output order, this indicates that the encoder considers one of the source scenes for the target pictures and the source scene for the next picture (in output order) to have been the same scene. When the value of `second_scene_id` is not equal to the value of `scene_id` or `second_scene_id` (when present) of the next picture in output order, this indicates that the encoder considers the target pictures and the next picture (in output order) to have been from different source scenes.

When the value of `scene_id` of a picture is equal to the value of `scene_id` of the following picture in output order and the value of `scene_transition_type` in both of these pictures is less than 4, this indicates that the encoder considers the two pictures to have been from the same source scene. When the values of `scene_id`, `scene_transition_type` and `second_scene_id` (when present) of a picture are equal to the values of `scene_id`, `scene_transition_type` and `second_scene_id` (respectively) of the following picture in output order and the value of `scene_transition_type` is greater than 0, this indicates that the encoder considers the two pictures to have been from the same source gradual scene transition.

The value of `second_scene_id` shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of `second_scene_id` in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of `second_scene_id` in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `second_scene_id` in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

D.3.10 Picture snapshot SEI message semantics

The picture snapshot SEI message indicates that the current picture is labelled for use as determined by the application as a still-image snapshot of the video content.

snapshot_id specifies a snapshot identification number. `snapshot_id` shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of `snapshot_id` in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of `snapshot_id` in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `snapshot_id` in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

D.3.11 Progressive refinement segment start SEI message semantics

The progressive refinement segment start SEI message specifies the beginning of a set of consecutive coded pictures in the current layer in decoding order that consists of the current picture and a sequence of one or more subsequent pictures in the current layer that refine the quality of the current picture, rather than a representation of a continually moving scene.

Let `picA` be the current picture. The tagged set of consecutive coded pictures `refinementPicSet` in the current layer consists of, in decoding order, the next picture in the current layer after the current picture in decoding order, when present, followed by zero or more pictures in the current layer, including all subsequent pictures in the current layer up to but not including any subsequent picture `picB` in the current layer for which one of the following conditions is true:

- The picture `picB` starts a new CLVS of the current layer.
- The value of `pic_order_cnt_delta` is greater than 0 and the `PicOrderCntVal` of the picture `picB`, i.e., `PicOrderCnt(picB)` is greater than `PicOrderCnt(picA) + pic_order_cnt_delta`, where `PicOrderCnt(picB)` and `PicOrderCnt(picA)` are the `PicOrderCntVal` values of `picB` and `picA`, respectively, immediately after the invocation of the decoding process for picture order count for `picB`.
- The picture `picB` is associated with a progressive refinement segment end SEI message that has the same `progressive_refinement_id` as the one in this SEI message and also applies to the current layer is decoded.

The decoding order of pictures within `refinementPicSet` should be the same as their output order.

progressive_refinement_id specifies an identification number for the progressive refinement operation. `progressive_refinement_id` shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of `progressive_refinement_id` in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of `progressive_refinement_id` in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `progressive_refinement_id` in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

pic_order_cnt_delta specifies the last picture in refinementPicSet in decoding order as follows:

- If **pic_order_cnt_delta** is equal to 0, the last picture in refinementPicSet in decoding order is the following picture:
 - If the CLVS contains one or more pictures in the current layer that follow the current picture in decoding order and are associated with a progressive refinement segment end SEI message that has the same **progressive_refinement_id** and also applies to the current layer, the last picture in refinementPicSet in decoding order is the first of these pictures in decoding order.
 - Otherwise, the last picture in refinementPicSet in decoding order is the last picture in the current layer within the CLVS in decoding order.
- Otherwise, the last picture in refinementPicSet in decoding order is the following picture:
 - If the CLVS contains one or more pictures in the current layer that follow the current picture in decoding order, that are associated with a progressive refinement segment end SEI message with the same **progressive_refinement_id** and applicable to the current layer, and that precede any picture **picC** in the current layer in the CLVS for which **PicOrderCnt(picC)** is greater than **PicOrderCnt(picA) + pic_order_cnt_delta**, where **PicOrderCnt(picC)** and **PicOrderCnt(picA)** are the **PicOrderCntVal** of the **picC** and **picA**, respectively, immediately after the invocation of the decoding process for picture order count for **picC**, the last picture in refinementPicSet in decoding order is the first of these pictures in decoding order.
 - Otherwise, if the CLVS contains one or more pictures **picD** in the current layer that follow the current picture in decoding order for which **PicOrderCnt(picD)** is greater than **PicOrderCnt(picA) + pic_order_cnt_delta**, where **PicOrderCnt(picD)** and **PicOrderCnt(picA)** are the **PicOrderCntVal** values of **picD** and **picA**, respectively, immediately after the invocation of the decoding process for picture order count for **picD**, the last picture in refinementPicSet in decoding order is the last picture in the current layer that precedes the first of these pictures in decoding order.
 - Otherwise, the last picture in refinementPicSet in decoding order is the last picture in the current layer within the CLVS in decoding order.

The value of **pic_order_cnt_delta** shall be in the range of 0 to 256, inclusive.

D.3.12 Progressive refinement segment end SEI message semantics

The progressive refinement segment end SEI message specifies the end of a set of consecutive coded pictures that has been labelled by use of a progressive refinement segment start SEI message as an initial picture followed by a sequence of one or more pictures of the refinement of the quality of the initial picture and ending with the current picture.

progressive_refinement_id specifies an identification number for the progressive refinement operation. **progressive_refinement_id** shall be in the range of 0 to $2^{32} - 2$, inclusive.

The progressive refinement segment end SEI message specifies the end of any progressive refinement segment previously started using a progressive refinement segment start SEI message with the same value of **progressive_refinement_id**.

Values of **progressive_refinement_id** in the range of 0 to 255, inclusive, and in the range of 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of **progressive_refinement_id** in the range of 256 to 511, inclusive, and in the range of 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of **progressive_refinement_id** in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

D.3.13 Film grain characteristics SEI message semantics

This SEI message provides the decoder with a parameterized model for film grain synthesis.

NOTE 1 – For example, an encoder could use the film grain characteristics SEI message to characterize film grain that was present in the original source video material and was removed by pre-processing filtering techniques. Synthesis of simulated film grain on the decoded images for the display process is optional and does not need to exactly follow the specified semantics of the film grain characteristics SEI message. When synthesis of simulated film grain on the decoded images for the display process is performed, there is no requirement that the method by which the synthesis is performed be the same as the parameterized model for the film grain as provided in the film grain characteristics SEI message.

NOTE 2 – The display process is not specified in this Specification.

NOTE 3 – SMPTE RDD 5 specifies a film grain simulator based on the information provided in the film grain characteristics SEI message.

The film grain models specified in the film grain characteristics SEI message are expressed for application to decoded pictures that have 4:4:4 colour format with luma and chroma bit depths corresponding to the luma and chroma bit depths of the film grain model and use the same colour representation domain as the identified film grain model. When the colour format of the decoded video is not 4:4:4 or the decoded video uses a different luma or chroma bit depth from that of the film grain model or uses a different colour representation domain from that of the identified film grain model, an unspecified conversion process is expected to be applied to convert the decoded pictures to the form that is expressed for application of the film grain model.

NOTE 4 – Because the use of a specific method is not required for performing the film grain generation function used by the display process, a decoder could, if desired, down-convert the model information for chroma in order to simulate film grain for other chroma formats (4:2:0 or 4:2:2) rather than up-converting the decoded video (using a method not specified in this Specification) before performing film grain generation.

film_grain_characteristics_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous film grain characteristics SEI message in output order that applies to the current layer. **film_grain_characteristics_cancel_flag** equal to 0 indicates that film grain modelling information follows.

film_grain_model_id identifies the film grain simulation model as specified in Table D.4. The value of **film_grain_model_id** shall be in the range of 0 to 1, inclusive. The values of 2 and 3 for **film_grain_model_id** are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore film grain characteristic SEI messages with **film_grain_model_id** equal to 2 or 3.

Table D.4 – film_grain_model_id values

Value	Description
0	Frequency filtering
1	Auto-regression

separate_colour_description_present_flag equal to 1 indicates that a distinct combination of luma bit depth, chroma bit depth, video full range flag, colour primaries, transfer characteristics, and matrix coefficients for the film grain characteristics specified in the SEI message is present in the film grain characteristics SEI message syntax. **separate_colour_description_present_flag** equal to 0 indicates that the combination of luma bit depth, chroma bit depth, video full range flag, colour primaries, transfer characteristics, and matrix coefficients for the film grain characteristics specified in the SEI message are the same as indicated in the VUI parameters for the CVS.

NOTE 5 – When **separate_colour_description_present_flag** is equal to 1, any of the luma bit depth, chroma bit depth, video full range flag, colour primaries, transfer characteristics, and matrix coefficients specified for the film grain characteristics specified in the SEI message could differ from those for the pictures in the CVS.

When VUI parameters are not present for the CVS or the value of **colour_description_present_flag** is equal to 0, and equivalent information to that conveyed when **colour_description_present_flag** is equal to 1 is not conveyed by external means, **separate_colour_description_present_flag** shall be equal to 1.

The decoded image I_{decoded} used in the equations in this clause is in the same colour representation domain as the simulated film grain signal. Therefore, when any of these parameters does differ from that for the pictures in the CVS, the decoded image I_{decoded} used in the equations in this clause would be in a different colour representation domain than that for the pictures in the CVS. For example, when the value of **film_grain_bit_depth_luma_minus8** + 8 is greater than the bit depth of the luma component of the pictures in the CVS, the bit depth of I_{decoded} used in the equations in this clause is also greater than the bit depth of the luma component of the pictures in the CVS. In such a case, the decoded image I_{decoded} corresponding to an actual decoded picture would be generated by converting the actual decoded picture to be in the same colour representation domain as the simulated film grain signal. The process for converting the actual decoded pictures to the 4:4:4 colour format with same colour representation domain as the simulated film grain signal is not specified in this Specification.

film_grain_bit_depth_luma_minus8 plus 8 specifies the bit depth used for the luma component of the film grain characteristics specified in the SEI message. When **film_grain_bit_depth_luma_minus8** is not present in the film grain characteristics SEI message, the value of **film_grain_bit_depth_luma_minus8** is inferred to be equal to **bit_depth_luma_minus8**.

The value of **filmGrainBitDepth[0]** is derived as follows:

$$\text{filmGrainBitDepth}[0] = \text{film_grain_bit_depth_luma_minus8} + 8 \quad (\text{D-3})$$

film_grain_bit_depth_chroma_minus8 plus 8 specifies the bit depth used for the Cb and Cr components of the film grain characteristics specified in the SEI message. When **film_grain_bit_depth_chroma_minus8** is not present in the film grain characteristics SEI message, the value of **film_grain_bit_depth_chroma_minus8** is inferred to be equal to **bit_depth_chroma_minus8**.

The value of **filmGrainBitDepth[c]** for $c = 1$ and 2 is derived as follows:

$$\text{filmGrainBitDepth}[c] = \text{film_grain_bit_depth_chroma_minus8} + 8, \text{ with } c = 1, 2 \quad (\text{D-4})$$

film_grain_full_range_flag has the same semantics as specified in clause E.3.1 for the **video_full_range_flag** syntax element, except as follows:

- **film_grain_full_range_flag** specifies the video full range flag of the film grain characteristics specified in the SEI message, rather than the video full range flag used for the CVS.
- When **film_grain_full_range_flag** is not present in the film grain characteristics SEI message, the value of **film_grain_full_range_flag** is inferred to be equal to **video_full_range_flag**.

film_grain_colour_primaries has the same semantics as specified in clause E.3.1 for the **colour_primaries** syntax element, except as follows:

- **film_grain_colour_primaries** specifies the colour primaries of the film grain characteristics specified in the SEI message, rather than the colour primaries used for the CVS.
- When **film_grain_colour_primaries** is not present in the film grain characteristics SEI message, the value of **film_grain_colour_primaries** is inferred to be equal to **colour_primaries**.

film_grain_transfer_characteristics has the same semantics as specified in clause E.3.1 for the **transfer_characteristics** syntax element, except as follows:

- **film_grain_transfer_characteristics** specifies the transfer characteristics of the film grain characteristics specified in the SEI message, rather than the transfer characteristics used for the CVS.
- When **film_grain_transfer_characteristics** is not present in the film grain characteristics SEI message, the value of **film_grain_transfer_characteristics** is inferred to be equal to **transfer_characteristics**.

film_grain_matrix_coeffs has the same semantics as specified in clause E.3.1 for the **matrix_coeffs** syntax element, except as follows:

- **film_grain_matrix_coeffs** specifies the matrix coefficients of the film grain characteristics specified in the SEI message, rather than the matrix coefficients used for the CVS.
- When **film_grain_matrix_coeffs** is not present in the film grain characteristics SEI message, the value of **film_grain_matrix_coeffs** is inferred to be equal to **matrix_coeffs**.
- The values allowed for **film_grain_matrix_coeffs** are not constrained by the chroma format of the decoded pictures that is indicated by the value of **chroma_format_idc** for the semantics of the VUI parameters.

blending_mode_id identifies the blending mode used to blend the simulated film grain with the decoded images as specified in Table D.5. **blending_mode_id** shall be in the range of 0 to 1, inclusive. The values of 2 and 3 for **blending_mode_id** are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore film grain characteristic SEI messages with **blending_mode_id** equal to 2 or 3.

Table D.5 – blending_mode_id values

Value	Description
0	Additive
1	Multiplicative

Depending on the value of **blending_mode_id**, the blending mode is specified as follows:

- If **blending_mode_id** is equal to 0, the blending mode is additive as specified by:

$$I_{\text{grain}}[c][x][y] = \text{Clip3}(0, (1 \ll \text{filmGrainBitDepth}[c]) - 1, I_{\text{decoded}}[c][x][y] + G[c][x][y]) \quad (\text{D-5})$$

- Otherwise (**blending_mode_id** is equal to 1), the blending mode is multiplicative as specified by:

$$I_{\text{grain}}[c][x][y] = \text{Clip3}(0, (1 \ll \text{filmGrainBitDepth}[c]) - 1, I_{\text{decoded}}[c][x][y] + \text{Round}((I_{\text{decoded}}[c][x][y] * G[c][x][y]) \div ((1 \ll \text{bitDepth}[c]) - 1))) \quad (\text{D-6})$$

where $I_{\text{decoded}}[c][x][y]$ represents the sample value at coordinates x, y of the colour component c of the decoded image I_{decoded} , $G[c][x][y]$ is the simulated film grain value at the same position and colour component, and $\text{filmGrainBitDepth}[c]$ is the number of bits used for each sample in a fixed-length unsigned binary representation of the arrays $I_{\text{grain}}[c][x][y]$, $I_{\text{decoded}}[c][x][y]$, and $G[c][x][y]$, where $c = 0..2$, $x = 0..\text{pic_width_in_luma_samples} - 1$, and $y = 0..\text{pic_height_in_luma_samples} - 1$.

log2_scale_factor specifies a scale factor used in the film grain characterization equations.

comp_model_present_flag[c] equal to 0 indicates that film grain is not modelled on the c-th colour component, where c equal to 0 refers to the luma component, c equal to 1 refers to the Cb component, and c equal to 2 refers to the Cr component. **comp_model_present_flag[c]** equal to 1 indicates that syntax elements specifying modelling of film grain on colour component c are present in the SEI message.

When **separate_colour_description_present_flag** is equal to 0 and **chroma_format_idc** is equal to 0, the value of **comp_model_present_flag[1]** and **comp_model_present_flag[2]** shall be equal to 0.

num_intensity_intervals_minus1[c] plus 1 specifies the number of intensity intervals for which a specific set of model values has been estimated.

NOTE 6 – The intensity intervals could overlap in order to simulate multi-generational film grain.

num_model_values_minus1[c] plus 1 specifies the number of model values present for each intensity interval in which the film grain has been modelled. The value of **num_model_values_minus1[c]** shall be in the range of 0 to 5, inclusive.

intensity_interval_lower_bound[c][i] specifies the lower bound of the i-th intensity interval for which the set of model values applies.

intensity_interval_upper_bound[c][i] specifies the upper bound of the i-th intensity interval for which the set of model values applies.

The variable **intensityIntervalIdx[c][x][y][j]** represents the j-th index to the list of intensity intervals selected for the sample value $I_{\text{decoded}}[c][x][y]$ for $c = 0..2$, $x = 0..pic_width_in_luma_samples - 1$, $y = 0..pic_height_in_luma_samples - 1$, and $j = 0..numApplicableIntensityIntervals[c][x][y] - 1$, where **numApplicableIntensityIntervals[c][x][y]** is derived below.

Depending on the value of **film_grain_model_id**, the selection of one or more intensity intervals for the sample value $I_{\text{decoded}}[c][x][y]$ is specified as follows:

- The variable **numApplicableIntensityIntervals[c][x][y]** is initially set equal to 0.
- If **film_grain_model_id** is equal to 0, the following applies:
 - The top-left sample location (xB, yB) of the current 8x8 block b that contains the sample value $I_{\text{decoded}}[c][x][y]$ is derived as $(xB, yB) = (x / 8, y / 8)$.
 - The average value b_{avg} of the current 8x8 block b is derived as follows:

$$\begin{aligned}
 & \text{sum8x8} = 0 \\
 & \text{for}(i = 0; i < 8; i++) \\
 & \quad \text{for}(j = 0; j < 8; j++) \\
 & \quad \quad \text{sum8x8} += I_{\text{decoded}}[c][xB * 8 + i][yB * 8 + j] \\
 & b_{\text{avg}} = \text{Clip3}(0, 255, \\
 & \quad (\text{sum8x8} + (1 \ll (\text{filmGrainBitDepth}[c] - 3))) \gg (\text{filmGrainBitDepth}[c] - 2))
 \end{aligned} \tag{D-7}$$

- The values of **intensityIntervalIdx[c][x][y][j]** and **numApplicableIntensityIntervals[c][x][y]** are derived as follows:

$$\begin{aligned}
 & \text{for}(i = 0, j = 0; i \leq \text{num_intensity_intervals_minus1}[c]; i++) \\
 & \quad \text{if}(b_{\text{avg}} \geq \text{intensity_interval_lower_bound}[c][i] \\
 & \quad \quad \&\& b_{\text{avg}} \leq \text{intensity_interval_upper_bound}[c][i]) \{ \\
 & \quad \quad \text{intensityIntervalIdx}[c][x][y][j] = i \\
 & \quad \quad j++ \\
 & \quad \} \\
 & \text{numApplicableIntensityIntervals}[c][x][y] = j
 \end{aligned} \tag{D-8}$$

- Otherwise (**film_grain_model_id** is equal to 1), the values of **intensityIntervalIdx[c][x][y][j]** and **numApplicableIntensityIntervals[c][x][y]** are derived as follows:

$$\begin{aligned}
 & I_8[c][x][y] = (\text{filmGrainBitDepth}[c] == 8) ? (I_{\text{decoded}}[c][x][y] : \\
 & \quad \text{Clip3}(0, 255, (I_{\text{decoded}}[c][x][y] + \\
 & \quad \quad (1 \ll (\text{filmGrainBitDepth}[c] - 9))) \gg (\text{filmGrainBitDepth}[c] - 8))) \\
 & \text{for}(i = 0, j = 0; i \leq \text{num_intensity_intervals_minus1}[c]; i++) \\
 & \quad \text{if}(I_8[c][x][y] \geq \text{intensity_interval_lower_bound}[c][i] \&\& \\
 & \quad \quad I_8[c][x][y] \leq \text{intensity_interval_upper_bound}[c][i]) \{ \\
 & \quad \quad \text{intensityIntervalIdx}[c][x][y][j] = i \\
 & \quad \quad j++ \\
 & \quad \}
 \end{aligned} \tag{D-9}$$

}
 numApplicableIntensityIntervals[c][x][y] = j

Samples that do not fall into any of the defined intervals (i.e., those samples for which the value of numApplicableIntensityIntervals[c][x][y] is equal to 0) are not modified by the grain generation function. Samples that fall into more than one interval (i.e., those samples for which the value of numApplicableIntensityIntervals[c][x][y] is greater than 1) will originate multi-generation grain. Multi-generation grain results from adding the grain computed independently for each of the applicable intensity intervals.

In the equations in the remainder of this clause, the variable s_j in each instance of the list comp_model_value[c][s_j] is the value of intensityIntervalIdx[c][x][y][j] derived for the sample value $I_{\text{decoded}}[c][x][y]$.

comp_model_value[c][i][j] specifies the j -th model value present for the colour component c and the i -th intensity interval. The set of model values has different meaning depending on the value of film_grain_model_id.

The value of comp_model_value[c][i][j] is constrained as follows, and could be additionally constrained as specified elsewhere in this clause:

- If film_grain_model_id is equal to 0, comp_model_value[c][i][j] shall be in the range of 0 to $2^{\text{filmGrainBitDepth}[c]} - 1$, inclusive.
- Otherwise (film_grain_model_id is equal to 1), comp_model_value[c][i][j] shall be in the range of $-2^{(\text{filmGrainBitDepth}[c] - 1)}$ to $2^{(\text{filmGrainBitDepth}[c] - 1)} - 1$, inclusive.

Depending on the value of film_grain_model_id, the synthesis of the film grain is modelled as follows:

- If film_grain_model_id is equal to 0, a frequency filtering model enables simulating the original film grain for $c = 0..2$, $x = 0..\text{pic_width_in_luma_samples} - 1$ and $y = 0..\text{pic_height_in_luma_samples} - 1$ as specified by:

$$G[c][x][y] = (\text{comp_model_value}[c][s_j][0] * Q[c][x][y] + \text{comp_model_value}[c][s_j][5] * G[c - 1][x][y]) \gg \log2_scale_factor \quad (\text{D-10})$$

where $Q[c]$ is a two-dimensional random process generated by filtering 16×16 blocks gaussRv with random variable elements gaussRv_{ij} generated with a normalized Gaussian distribution (independent and identically distributed Gaussian random variable samples with zero mean and unity variance) and the value of an element $G[c - 1][x][y]$ used in the right-hand side of the equation is inferred to be equal to 0 when $c - 1$ is less than 0.

NOTE 7 – A normalized Gaussian random variable can be generated from two independent, uniformly distributed random variables over the interval from 0 to 1 (and not equal to 0), denoted as uRv₀ and uRv₁, using the Box-Muller transformation specified by:

$$\text{gaussRv}_{ij} = \text{Sqrt}(-2 * \text{Ln}(\text{uRv}_0)) * \text{Cos}(2 * \pi * \text{uRv}_1) \quad (\text{D-11})$$

where π is Archimedes' constant 3.141 592 653 589 793....

The band-pass filtering of blocks gaussRv can be performed in the discrete cosine transform (DCT) domain as follows:

```
for( y = 0; y < 16; y++ )
  for( x = 0; x < 16; x++ )
    if( ( x < comp_model_value[ c ][ s_j ][ 3 ] && y < comp_model_value[ c ][ s_j ][ 4 ] ) ||
        x > comp_model_value[ c ][ s_j ][ 1 ] || y > comp_model_value[ c ][ s_j ][ 2 ] )
      gaussRv[ x ][ y ] = 0
  filteredRv = IDCT16x16( gaussRv )
```

where IDCT16x16(z) refers to a unitary inverse discrete cosine transformation (IDCT) operating on a 16×16 matrix argument z as specified by:

$$\text{IDCT16x16}(z) = r * z * r^T \quad (\text{D-13})$$

where the superscript T indicates a matrix transposition and r is the 16×16 matrix with elements r_{ij} specified by:

$$r_{i,j} = \frac{((i == 0) ? 1 : \text{Sqrt}(2))}{4} * \text{Cos}\left(\frac{i * (2 * j + 1) * \pi}{32}\right) \quad (\text{D-14})$$

where π is Archimedes' constant 3.141 592 653 589 793....

$Q[c]$ is formed by the frequency-filtered blocks filteredRv.

NOTE 8 – Coded model values are based on blocks of size 16x16, but a decoder implementation could use other block sizes. For example, decoders implementing the IDCT on 8x8 blocks could down-convert by a factor of two the set of coded model values $\text{comp_model_value}[c][s_j][i]$ for i equal to 1..4.

NOTE 9 – To reduce the degree of visible blocks that can result from mosaicking the frequency-filtered blocks filteredRv, decoders could apply a low-pass filter to the boundaries between frequency-filtered blocks.

- Otherwise ($\text{film_grain_model_id}$ is equal to 1), an auto-regression model enables simulating the original film grain for $c = 0..2$, $x = 0..\text{pic_width_in_luma_samples} - 1$, and $y = 0..\text{pic_height_in_luma_samples} - 1$ as specified by:

$$\begin{aligned} G[c][x][y] = & (\text{comp_model_value}[c][s_j][0] * n[c][x][y] + \\ & \text{comp_model_value}[c][s_j][1] * (G[c][x-1][y] + ((\text{comp_model_value}[c][s_j][4] * \\ & G[c][x][y-1]) >> \log_2_scale_factor)) + \\ & \text{comp_model_value}[c][s_j][3] * (((\text{comp_model_value}[c][s_j][4] * G[c][x-1][y-1]) >> \\ & \log_2_scale_factor) + G[c][x+1][y-1]) + \\ & \text{comp_model_value}[c][s_j][5] * (G[c][x-2][y] + \\ & ((\text{comp_model_value}[c][s_j][4] * \text{comp_model_value}[c][s_j][4] * G[c][x][y-2]) >> \\ & (2 * \log_2_scale_factor))) + \\ & \text{comp_model_value}[c][s_j][2] * G[c-1][x][y]) >> \log_2_scale_factor \end{aligned} \quad (D-15)$$

where $n[c][x][y]$ is a random variable with normalized Gaussian distribution (independent and identically distributed Gaussian random variable samples with zero mean and unity variance for each value of c , x , and y) and the value of an element $G[c][x][y]$ used in the right-hand side of the equation is inferred to be equal to 0 when any of the following conditions are true:

- x is less than 0,
- y is less than 0,
- c is less than 0.

$\text{comp_model_value}[c][i][0]$ provides the first model value for the model as specified by $\text{film_grain_model_id}$. $\text{comp_model_value}[c][i][0]$ corresponds to the standard deviation of the Gaussian noise term in the generation functions specified in Equations D-10 through D-15.

$\text{comp_model_value}[c][i][1]$ provides the second model value for the model as specified by $\text{film_grain_model_id}$. When $\text{film_grain_model_id}$ is equal to 0, $\text{comp_model_value}[c][i][1]$ shall be greater than or equal to 0 and less than 16.

When not present in the film grain characteristics SEI message, $\text{comp_model_value}[c][i][1]$ is inferred as follows:

- If $\text{film_grain_model_id}$ is equal to 0, $\text{comp_model_value}[c][i][1]$ is inferred to be equal to 8.
- Otherwise ($\text{film_grain_model_id}$ is equal to 1), $\text{comp_model_value}[c][i][1]$ is inferred to be equal to 0.

$\text{comp_model_value}[c][i][1]$ is interpreted as follows:

- If $\text{film_grain_model_id}$ is equal to 0, $\text{comp_model_value}[c][i][1]$ indicates the horizontal high cut frequency to be used to filter the DCT of a block of 16x16 random values.
- Otherwise ($\text{film_grain_model_id}$ is equal to 1), $\text{comp_model_value}[c][i][1]$ indicates the first order spatial correlation for neighbouring samples at positions $(x-1, y)$ and $(x, y-1)$.

$\text{comp_model_value}[c][i][2]$ provides the third model value for the model as specified by $\text{film_grain_model_id}$. When $\text{film_grain_model_id}$ is equal to 0, $\text{comp_model_value}[c][i][2]$ shall be greater than or equal to 0 and less than 16.

When not present in the film grain characteristics SEI message, $\text{comp_model_value}[c][i][2]$ is inferred as follows:

- If $\text{film_grain_model_id}$ is equal to 0, $\text{comp_model_value}[c][i][2]$ is inferred to be equal to $\text{comp_model_value}[c][i][1]$
- Otherwise ($\text{film_grain_model_id}$ is equal to 1), $\text{comp_model_value}[c][i][2]$ is inferred to be equal to 0.

$\text{comp_model_value}[c][i][2]$ is interpreted as follows:

- If $\text{film_grain_model_id}$ is equal to 0, $\text{comp_model_value}[c][i][2]$ indicates the vertical high cut frequency to be used to filter the DCT of a block of 16x16 random values.
- Otherwise ($\text{film_grain_model_id}$ is equal to 1), $\text{comp_model_value}[c][i][2]$ indicates the colour correlation between consecutive colour components.

`comp_model_value[c][i][3]` provides the fourth model value for the model as specified by `film_grain_model_id`. When `film_grain_model_id` is equal to 0, `comp_model_value[c][i][3]` shall be greater than or equal to 0 and less than or equal to `comp_model_value[c][i][1]`.

When not present in the film grain characteristics SEI message, `comp_model_value[c][i][3]` is inferred to be equal to 0.

`comp_model_value[c][i][3]` is interpreted as follows:

- If `film_grain_model_id` is equal to 0, `comp_model_value[c][i][3]` indicates the horizontal low cut frequency to be used to filter the DCT of a block of 16x16 random values.
- Otherwise (`film_grain_model_id` is equal to 1), `comp_model_value[c][i][3]` indicates the first order spatial correlation for neighbouring samples at positions $(x - 1, y - 1)$ and $(x + 1, y - 1)$.

`comp_model_value[c][i][4]` provides the fifth model value for the model as specified by `film_grain_model_id`. When `film_grain_model_id` is equal to 0, `comp_model_value[c][i][4]` shall be greater than or equal to 0 and less than or equal to `comp_model_value[c][i][2]`.

When not present in the film grain characteristics SEI message, `comp_model_value[c][i][4]` is inferred to be equal to `film_grain_model_id`.

`comp_model_value[c][i][4]` is interpreted as follows:

- If `film_grain_model_id` is equal to 0, `comp_model_value[c][i][4]` indicates the vertical low cut frequency to be used to filter the DCT of a block of 16x16 random values.
- Otherwise (`film_grain_model_id` is equal to 1), `comp_model_value[c][i][4]` indicates the aspect ratio of the modelled grain.

`comp_model_value[c][i][5]` provides the sixth model value for the model as specified by `film_grain_model_id`.

When not present in the film grain characteristics SEI message, `comp_model_value[c][i][5]` is inferred to be equal to 0.

`comp_model_value[c][i][5]` is interpreted as follows:

- If `film_grain_model_id` is equal to 0, `comp_model_value[c][i][5]` indicates the colour correlation between consecutive colour components.
- Otherwise (`film_grain_model_id` is equal to 1), `comp_model_value[c][i][5]` indicates the second order spatial correlation for neighbouring samples at positions $(x, y - 2)$ and $(x - 2, y)$.

film_grain_characteristics_persistence_flag specifies the persistence of the film grain characteristics SEI message for the current layer.

`film_grain_characteristics_persistence_flag` equal to 0 specifies that the film grain characteristics SEI message applies to the current decoded picture only.

Let `picA` be the current picture. `film_grain_characteristics_persistence_flag` equal to 1 specifies that the film grain characteristics SEI message persists for the current layer in output order until any of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture `picB` in the current layer in an access unit containing a film grain characteristics SEI message that is applicable to the current layer is output for which `PicOrderCnt(picB)` is greater than `PicOrderCnt(picA)`, where `PicOrderCnt(picB)` and `PicOrderCnt(picA)` are the `PicOrderCntVal` values of `picB` and `picA`, respectively, immediately after the invocation of the decoding process for picture order count for `picB`.

D.3.14 Post-filter hint SEI message semantics

This SEI message provides the coefficients of a post-filter or correlation information for the design of a post-filter for potential use in post-processing of the current picture after it is decoded and output to obtain improved displayed quality.

filter_hint_size_y specifies the vertical size of the filter coefficient or correlation array. The value of `filter_hint_size_y` shall be in the range of 1 to 15, inclusive.

filter_hint_size_x specifies the horizontal size of the filter coefficient or correlation array. The value of `filter_hint_size_x` shall be in the range of 1 to 15, inclusive.

filter_hint_type identifies the type of the transmitted filter hints as specified in Table D.6. The value of `filter_hint_type` shall be in the range of 0 to 2, inclusive. The value of `filter_hint_type` equal to 3 is reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore post-filter hint SEI messages having `filter_hint_type` equal to 3.

Table D.6 – filter_hint_type values

Value	Description
0	Coefficients of a 2D-FIR filter
1	Coefficients of two 1D-FIR filters
2	Cross-correlation matrix

filter_hint_value[cIdx][cy][cx] specifies a filter coefficient or an element of a cross-correlation matrix between the original and the decoded signal with 16-bit precision. The value of **filter_hint_value**[cIdx][cy][cx] shall be in the range of $-2^{31} + 1$ to $2^{31} - 1$, inclusive. cIdx specifies the related colour component, cy represents a counter in vertical direction and cx represents a counter in horizontal direction. Depending on the value of **filter_hint_type**, the following applies:

- If **filter_hint_type** is equal to 0, the coefficients of a 2-dimensional finite impulse response (FIR) filter with the size of **filter_hint_size_y** * **filter_hint_size_x** are transmitted.
- Otherwise, if **filter_hint_type** is equal to 1, the filter coefficients of two 1-dimensional FIR filters are transmitted. In this case, **filter_hint_size_y** shall be equal to 2. The index cy equal to 0 specifies the filter coefficients of the horizontal filter and cy equal to 1 specifies the filter coefficients of the vertical filter. In the filtering process, the horizontal filter is applied first and the result is filtered by the vertical filter.
- Otherwise (**filter_hint_type** is equal to 2), the transmitted hints specify a cross-correlation matrix between the original signal *s* and the decoded signal *s'*.

NOTE 1 – The normalized cross-correlation matrix for a related colour component identified by cIdx with the size of **filter_hint_size_y** * **filter_hint_size_x** is defined as follows:

$$\text{filter_hint_value}(\text{cIdx}, \text{cy}, \text{cx}) = \frac{1}{(2^{8+\text{bitDepth}} - 1)^2 * h * w} \sum_{m=0}^{h-1} \sum_{n=0}^{w-1} s(m, n) * s'(m + \text{cy} - \text{OffsetY}, n + \text{cx} - \text{OffsetX}) \quad (\text{D-16})$$

where *s* denotes array of samples of the colour component cIdx of the original picture, *s'* denotes corresponding array of the decoded picture, *h* denotes the vertical height of the related colour component, *w* denotes the horizontal width of the related colour component, bitDepth denotes the bit depth of the colour component, OffsetY is equal to (**filter_hint_size_y** >> 1), OffsetX is equal to (**filter_hint_size_x** >> 1), $0 \leq \text{cy} < \text{filter_hint_size_y}$ and $0 \leq \text{cx} < \text{filter_hint_size_x}$.

NOTE 2 – A decoder can derive a Wiener post-filter from the cross-correlation matrix of original and decoded signal and the auto-correlation matrix of the decoded signal.

D.3.15 Tone mapping information SEI message semantics

This SEI message provides information to enable remapping of the colour samples of the output decoded pictures for customization to particular display environments. The remapping process maps coded sample values in the RGB colour space (specified in Annex E) to target sample values. The mappings are expressed either in the luma or RGB colour space domain and should be applied to the luma component or to each RGB component produced by colour space conversion of the decoded image accordingly.

tone_map_id contains an identifying number that may be used to identify the purpose of the tone mapping model. The value of **tone_map_id** shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of **tone_map_id** from 0 to 255, inclusive, and from 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of **tone_map_id** from 256 to 511, inclusive, and from 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of **tone_map_id** in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

NOTE 1 – The **tone_map_id** can be used to support tone mapping operations that are suitable for different display scenarios. For example, different values of **tone_map_id** may correspond to different display bit depths.

tone_map_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous tone mapping information SEI message in output order that applies to the current layer. **tone_map_cancel_flag** equal to 0 indicates that tone mapping information follows.

tone_map_persistence_flag specifies the persistence of the tone mapping information SEI message.

tone_map_persistence_flag equal to 0 specifies that the tone mapping information applies to the current decoded picture only.

Let `picA` be the current picture. `tone_map_persistence_flag` equal to 1 specifies that the tone mapping information persists for the current layer in output order until any of the following conditions are true:

- A new CLVS of the current layer begins.
- A picture `picB` in the current layer in an access unit containing a tone mapping information SEI message with the same value of `tone_map_id` and applicable to the current layer is output for which `PicOrderCnt(picB)` is greater than `PicOrderCnt(picA)`, where `PicOrderCnt(picB)` and `PicOrderCnt(picA)` are the `PicOrderCntVal` values of `picB` and `picA`, respectively, immediately after the invocation of the decoding process for picture order count for `picB`.

coded_data_bit_depth specifies the `BitDepthY` for interpretation of the luma component of the associated pictures for purposes of interpretation of the tone mapping information SEI message. When tone mapping information SEI messages are present that have `coded_data_bit_depth` that is not equal to `BitDepthY`, these refer to the hypothetical result of a transcoding operation performed to convert the coded video to the `BitDepthY` corresponding to the value of `coded_data_bit_depth`.

The value of `coded_data_bit_depth` shall be in the range of 8 to 14, inclusive. Values of `coded_data_bit_depth` from 0 to 7 and from 15 to 255 are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore all tone mapping SEI messages that contain a `coded_data_bit_depth` in the range of 0 to 7, inclusive, or in the range of 15 to 255, inclusive, and bitstreams shall not contain such values.

target_bit_depth specifies the bit depth of the output of the dynamic range mapping function (or tone mapping function) described by the tone mapping information SEI message. The tone mapping function specified with a particular `target_bit_depth` is suggested to be reasonable for all display bit depths that are less than or equal to the `target_bit_depth`.

The value of `target_bit_depth` shall be in the range of 1 to 16, inclusive. Values of `target_bit_depth` equal to 0 and in the range of 17 to 255, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore all tone mapping SEI messages that contain a value of `target_bit_depth` equal to 0 or in the range of 17 to 255, inclusive, and bitstreams shall not contain such values.

tone_map_model_id specifies the model utilized for mapping the coded data into the `target_bit_depth` range. Values greater than 4 are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore all tone mapping SEI messages that contain a value of `tone_map_model_id` greater than 4 and bitstreams shall not contain such values.

NOTE 2 – A `tone_map_model_id` of 0 corresponds to a linear mapping with clipping; a `tone_map_model_id` of 1 corresponds to a sigmoidal mapping; a `tone_map_model_id` of 2 corresponds to a user-defined table mapping, and a `tone_map_model_id` of 3 corresponds to a piece-wise linear mapping, `tone_map_model_id` of 4 corresponds to luminance dynamic range information.

min_value specifies the RGB sample value that maps to the minimum value in the bit depth indicated by `target_bit_depth`. It is used in combination with the `max_value` parameter. All sample values in the decoded picture that are less than or equal to `min_value`, after conversion to RGB as necessary, are mapped to this minimum value in the `target_bit_depth` representation.

max_value specifies the RGB sample value that maps to the maximum value in the bit depth indicated by `target_bit_depth`. It is used in combination with the `min_value` parameter. All sample values in the decoded picture that are greater than or equal to `max_value`, after conversion to RGB as necessary, are mapped to this maximum value in the `target_bit_depth` representation.

When present, `max_value` shall be greater than or equal to `min_value`.

sigmoid_midpoint specifies the RGB sample value of the coded data that are mapped to the centre point of the `target_bit_depth` representation. It is used in combination with the `sigmoid_width` parameter.

sigmoid_width specifies the distance between two coded data values that approximately correspond to the 5% and 95% values of the `target_bit_depth` representation, respectively. It is used in combination with the `sigmoid_midpoint` parameter and is interpreted according to the following function:

$$f(i) = \text{Round} \left(\frac{2^{\text{target_bit_depth} - 1}}{1 + \exp \left(\frac{-6 * (i - \text{sigmoid_midpoint})}{\text{sigmoid_width}} \right)} \right) \quad (\text{D-17})$$

where $f(i)$ denotes the function that maps an RGB sample value i from the coded data to a resulting RGB sample value in the `target_bit_depth` representation.

start_of_coded_interval[i] specifies the beginning point of an interval in the coded data such that all RGB sample values that are greater than or equal to `start_of_coded_interval[i]` and less than `start_of_coded_interval[i + 1]` are mapped to i

in the target bit depth representation. The value of `start_of_coded_interval[2target_bit_depth]` is equal to `2coded_data_bit_depth`. The number of bits used for the representation of the `start_of_coded_interval` is $((\text{coded_data_bit_depth} + 7) \gg 3) \ll 3$.

num_pivots specifies the number of pivot points in the piece-wise linear mapping function without counting the two default end points, (0, 0) and $(2^{\text{coded_data_bit_depth}} - 1, 2^{\text{target_bit_depth}} - 1)$.

coded_pivot_value[i] specifies the value in the `coded_data_bit_depth` corresponding to the *i*-th pivot point. The number of bits used for the representation of the `coded_pivot_value` is $((\text{coded_data_bit_depth} + 7) \gg 3) \ll 3$.

target_pivot_value[i] specifies the value in the reference `target_bit_depth` corresponding to the *i*-th pivot point. The number of bits used for the representation of the `target_pivot_value` is $((\text{target_bit_depth} + 7) \gg 3) \ll 3$.

camera_iso_speed_idc indicates the camera ISO speed for daylight illumination as specified in ISO 12232, interpreted as specified in Table D.7. When `camera_iso_speed_idc` indicates EXTENDED_ISO, the ISO speed is indicated by `camera_iso_speed_value`.

camera_iso_speed_value indicates the camera ISO speed for daylight illumination as specified in ISO 12232 when `camera_iso_speed_idc` indicates EXTENDED_ISO. The value of `camera_iso_speed_value` shall not be equal to 0.

exposure_idx_idc indicates the exposure index setting of the camera as specified in ISO 12232, interpreted as specified in Table D.7. When `exposure_idx_idc` indicates EXTENDED_ISO, the exposure index is indicated by `exposure_idx_value`.

The values of `camera_iso_speed_idc` and `exposure_idx_idc` in the range of 31 to 254, inclusive, are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders conforming to this version of this Specification shall ignore tone mapping SEI messages that contain these values.

exposure_idx_value indicates the exposure index setting of the camera as specified in ISO 12232 when `exposure_idx_idc` indicates EXTENDED_ISO. The value of `exposure_idx_value` shall not be equal to 0.

Table D.7 – Interpretation of camera_iso_speed_idc and exposure_idx_idc

camera_iso_speed_idc or exposure_idx_idc	Indicated value
0	Unspecified
1	10
2	12
3	16
4	20
5	25
6	32
7	40
8	50
9	64
10	80
11	100
12	125
13	160
14	200
15	250
16	320
17	400
18	500
19	640
20	800
21	1 000
22	1 250
23	1 600
24	2 000
25	2 500
26	3 200
27	4 000
28	5 000
29	6 400
30	8 000
31..254	Reserved
255	EXTENDED_ISO

exposure_compensation_value_sign_flag, when applicable as specified below, specifies the sign of the variable ExposureCompensationValue that indicates the exposure compensation value setting used for the process of image production.

exposure_compensation_value_numerator, when applicable as specified below, specifies the numerator of the variable ExposureCompensationValue that indicates the exposure compensation value setting used for the process of image production.

exposure_compensation_value_denom_idc, when not equal to 0, specifies the denominator of the variable ExposureCompensationValue that indicates the exposure compensation value setting used for the process of image production.

When `exposure_compensation_value_denom_idc` is present and not equal to 0, the variable `ExposureCompensationValue` is derived from `exposure_compensation_value_sign_flag`, `exposure_compensation_value_numerator` and `exposure_compensation_value_denom_idc`. `exposure_compensation_value_sign_flag` equal to 0 indicates that the `ExposureCompensationValue` is positive. `exposure_compensation_value_sign_flag` equal to 1 indicates that the `ExposureCompensationValue` is negative. When `ExposureCompensationValue` is positive, the image is indicated to have been further sensitized through the process of production, relative to the recommended exposure index of the camera as specified in ISO 12232. When `ExposureCompensationValue` is negative, the image is indicated to have been further desensitized through the process of production, relative to the recommended exposure index of the camera as specified in ISO 12232.

When `exposure_compensation_value_denom_idc` is present and not equal to 0, the variable `ExposureCompensationValue` is derived as follows:

$$\text{ExposureCompensationValue} = (1 - 2 * \text{exposure_compensation_value_sign_flag}) * \frac{\text{exposure_compensation_value_numerator}}{\text{exposure_compensation_value_denom_idc}}$$

(D-18)

The value of `ExposureCompensationValue` is interpreted in units of exposure steps such that an increase of 1 in `ExposureCompensationValue` corresponds to a doubling of exposure in units of lux-seconds. For example, the exposure compensation value equal to $+1 \div 2$ at the production stage may be indicated by setting `exposure_compensation_value_sign_flag` to 0, `exposure_compensation_value_numerator` to 1 and `exposure_compensation_value_denom_idc` to 2.

When `exposure_compensation_value_denom_idc` is present and equal to 0, the exposure compensation value is indicated as unknown or unspecified.

ref_screen_luminance_white indicates the reference screen brightness setting for the extended white level used for image production process in units of candelas per square metre.

extended_range_white_level indicates the luminance dynamic range for extended dynamic-range display of the associated pictures, after conversion to the linear light domain for display, expressed as an integer percentage relative to the nominal white level. The value of `extended_range_white_level` should be greater than or equal to 100.

nominal_black_level_code_value indicates the luma sample value of the associated decoded pictures to which the nominal black level is assigned. For example, when `coded_data_bit_depth` is equal to 8, `video_full_range_flag` is equal to 0, and `matrix_coeffs` is equal to 1, `nominal_black_level_code_value` should be equal to 16.

nominal_white_level_code_value indicates the luma sample value of the associated decoded pictures to which the nominal white level is assigned. For example, when `coded_data_bit_depth` is equal to 8, `video_full_range_flag` is equal to 0 and `matrix_coeffs` is equal to 1, `nominal_white_level_code_value` should be equal to 235. When present, the value of `nominal_white_level_code_value` shall be greater than `nominal_black_level_code_value`.

extended_white_level_code_value indicates the luma sample value of the associated decoded pictures to which the white level associated with an extended dynamic range is assigned. When present, the value of `extended_white_level_code_value` shall be greater than or equal to `nominal_white_level_code_value`.

D.3.16 Frame packing arrangement SEI message semantics

This SEI message informs the decoder that the output cropped decoded picture contains samples of multiple distinct spatially packed constituent frames that are packed into one frame, or that the output cropped decoded pictures in output order form a temporal interleaving of alternating first and second constituent frames, using an indicated frame packing arrangement scheme. This information can be used by the decoder to appropriately rearrange the samples and process the samples of the constituent frames appropriately for display or other purposes (which are outside the scope of this Specification).

This SEI message may be associated with pictures that are either frames (when `field_seq_flag` is equal to 0) or fields (when `field_seq_flag` is equal to 1). The frame packing arrangement of the samples is specified in terms of the sampling structure of a frame in order to define a frame packing arrangement structure that is invariant with respect to whether a picture is a single field of such a packed frame or is a complete packed frame.

When `general_non_packed_constraint_flag` is equal to 1 for a CVS, there shall be no frame packing arrangement SEI messages in the CVS.

frame_packing_arrangement_id contains an identifying number that may be used to identify the usage of the frame packing arrangement SEI message. The value of `frame_packing_arrangement_id` shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of `frame_packing_arrangement_id` from 0 to 255, inclusive, and from 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of `frame_packing_arrangement_id` from 256 to 511, inclusive, and from 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `frame_packing_arrangement_id` in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

`frame_packing_arrangement_cancel_flag` equal to 1 indicates that the SEI message cancels the persistence of any previous frame packing arrangement SEI message in output order that applies to the current layer. `frame_packing_arrangement_cancel_flag` equal to 0 indicates that frame packing arrangement information follows.

`frame_packing_arrangement_type` identifies the indicated interpretation of the sample arrays of the output cropped decoded picture as specified in Table D.8.

When `frame_packing_arrangement_type` is equal to 3 or 4, each component plane of the output cropped decoded picture contains all samples (when `field_pic_flag` is equal to 0) or the samples corresponding to the top or bottom field (when `field_pic_flag` is equal to 1) of the samples of a frame packing arrangement structure.

Table D.8 – Definition of `frame_packing_arrangement_type`

Value	Interpretation
3	The frame packing arrangement structure contains a side-by-side packing arrangement of corresponding planes of two constituent frames as illustrated in Figure D.4, Figure D.5 and Figure D.8.
4	The frame packing arrangement structure contains a top-bottom packing arrangement of corresponding planes of two constituent frames as illustrated in Figure D.6 and Figure D.7.
5	The component planes of the output cropped decoded pictures in output order form a temporal interleaving of alternating first and second constituent frames as illustrated in Figure D.9.

NOTE 1 – Figure D.4 to Figure D.8 provide typical examples of rearrangement and upconversion processing for various packing arrangement schemes. Actual characteristics of the constituent frames are signalled in detail by the subsequent syntax elements of the frame packing arrangement SEI message. In Figure D.4 to Figure D.8, an upconversion processing is performed on each constituent frame to produce frames having the same resolution as that of the decoded frame. An example of the upsampling method to be applied to a quincunx sampled frame as shown in Figure D.8 is to fill in missing positions with an average of the available spatially neighbouring samples (the average of the values of the available samples above, below, to the left and to the right of each sample to be generated). The actual upconversion process to be performed, if any, is outside the scope of this Specification.

NOTE 2 – When the output time of the samples of constituent frame 0 differs from the output time of the samples of constituent frame 1 (i.e., when `field_views_flag` is equal to 1 or `frame_packing_arrangement_type` is equal to 5) and the display system in use presents two views simultaneously, the display time for constituent frame 0 should be delayed to coincide with the display time for constituent frame 1. (The display process is not specified in this Specification.)

NOTE 3 – When `field_views_flag` is equal to 1 or `frame_packing_arrangement_type` is equal to 5, the value 0 for `fixed_pic_rate_within_cvs_flag` is not expected to be prevalent in industry use of this SEI message.

NOTE 4 – `frame_packing_arrangement_type` equal to 5 describes a temporal interleaving process of different views.

All other values of `frame_packing_arrangement_type` are reserved for future use by ITU-T | ISO/IEC. It is a requirement of bitstream conformance that bitstreams conforming to this version of this Specification shall not contain such other values of `frame_packing_arrangement_type`. Decoders shall ignore frame packing arrangement SEI messages that contain reserved values of `frame_packing_arrangement_type`.

`quincunx_sampling_flag` equal to 1 indicates that each colour component plane of each constituent frame is quincunx sampled as illustrated in Figure D.8 and `quincunx_sampling_flag` equal to 0 indicates that the colour component planes of each constituent frame are not quincunx sampled.

When `frame_packing_arrangement_type` is equal to 5, it is a requirement of bitstream conformance that `quincunx_sampling_flag` shall be equal to 0.

NOTE 5 – For any chroma format (4:2:0, 4:2:2 or 4:4:4), the luma plane and each chroma plane is quincunx sampled as illustrated in Figure D.8 when `quincunx_sampling_flag` is equal to 1.

`content_interpretation_type` indicates the intended interpretation of the constituent frames as specified in Table D.9. Values of `content_interpretation_type` that do not appear in Table D.9 are reserved for future specification by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore frame packing arrangement SEI messages that contain reserved values of `content_interpretation_type`.

For each specified frame packing arrangement scheme, there are two constituent frames that are referred to as frame 0 and frame 1.

Table D.9 – Definition of content_interpretation_type

Value	Interpretation
0	Unspecified relationship between the frame packed constituent frames
1	Indicates that the two constituent frames form the left and right views of a stereo view scene, with frame 0 being associated with the left view and frame 1 being associated with the right view
2	Indicates that the two constituent frames form the right and left views of a stereo view scene, with frame 0 being associated with the right view and frame 1 being associated with the left view

NOTE 6 – The value 2 for content_interpretation_type is not expected to be prevalent in industry use of this SEI message. However, the value was specified herein for purposes of completeness.

spatial_flipping_flag equal to 1, when frame_packing_arrangement_type is equal to 3 or 4, indicates that one of the two constituent frames is spatially flipped relative to its intended orientation for display or other such purposes.

When frame_packing_arrangement_type is equal to 3 or 4 and spatial_flipping_flag is equal to 1, the type of spatial flipping that is indicated is as follows:

- If frame_packing_arrangement_type is equal to 3, the indicated spatial flipping is horizontal flipping.
- Otherwise (frame_packing_arrangement_type is equal to 4), the indicated spatial flipping is vertical flipping.

When frame_packing_arrangement_type is not equal to 3 or 4, it is a requirement of bitstream conformance that spatial_flipping_flag shall be equal to 0. When frame_packing_arrangement_type is not equal to 3 or 4, the value 1 for spatial_flipping_flag is reserved for future use by ITU-T | ISO/IEC. When frame_packing_arrangement_type is not equal to 3 or 4, decoders shall ignore the value 1 for spatial_flipping_flag.

frame0_flipped_flag, when spatial_flipping_flag is equal to 1, indicates which one of the two constituent frames is flipped.

When spatial_flipping_flag is equal to 1, frame0_flipped_flag equal to 0 indicates that frame 0 is not spatially flipped and frame 1 is spatially flipped and frame0_flipped_flag equal to 1 indicates that frame 0 is spatially flipped and frame 1 is not spatially flipped.

When spatial_flipping_flag is equal to 0, it is a requirement of bitstream conformance that frame0_flipped_flag shall be equal to 0. When spatial_flipping_flag is equal to 0, the value 1 for spatial_flipping_flag is reserved for future use by ITU-T | ISO/IEC. When spatial_flipping_flag is equal to 0, decoders shall ignore the value of frame0_flipped_flag.

field_views_flag equal to 1 indicates that all pictures in the current CVS are coded as fields, all fields of a particular parity are considered a first constituent frame and all fields of the opposite parity are considered a second constituent frame. It is a requirement of bitstream conformance that the field_views_flag shall be equal to 0, the value 1 for field_views_flag is reserved for future use by ITU-T | ISO/IEC and decoders shall ignore the value of field_views_flag.

current_frame_is_frame0_flag equal to 1, when frame_packing_arrangement_type is equal to 5, indicates that the current decoded frame is constituent frame 0 and the next decoded frame in output order is constituent frame 1 and the display time of the constituent frame 0 should be delayed to coincide with the display time of constituent frame 1. current_frame_is_frame0_flag equal to 0, when frame_packing_arrangement_type is equal to 5, indicates that the current decoded frame is constituent frame 1 and the previous decoded frame in output order is constituent frame 0 and the display time of the constituent frame 1 should not be delayed for purposes of stereo-view pairing.

When frame_packing_arrangement_type is not equal to 5, the constituent frame associated with the upper-left sample of the decoded frame is considered to be constituent frame 0 and the other constituent frame is considered to be constituent frame 1. When frame_packing_arrangement_type is not equal to 5, it is a requirement of bitstream conformance that current_frame_is_frame0_flag shall be equal to 0. When frame_packing_arrangement_type is not equal to 5, the value 1 for current_frame_is_frame0_flag is reserved for future use by ITU-T | ISO/IEC. When frame_packing_arrangement_type is not equal to 5, decoders shall ignore the value of current_frame_is_frame0_flag.

frame0_self_contained_flag equal to 1 indicates that no inter prediction operations within the decoding process for the samples of constituent frame 0 of the CVS refer to samples of any constituent frame 1. frame0_self_contained_flag equal to 0 indicates that some inter prediction operations within the decoding process for the samples of constituent frame 0 of the CVS may or may not refer to samples of some constituent frame 1. Within a CVS, the value of frame0_self_contained_flag in all frame packing arrangement SEI messages shall be the same.

frame1_self_contained_flag equal to 1 indicates that no inter prediction operations within the decoding process for the samples of constituent frame 1 of the CVS refer to samples of any constituent frame 0. **frame1_self_contained_flag** equal to 0 indicates that some inter prediction operations within the decoding process for the samples of constituent frame 1 of the CVS may or may not refer to samples of some constituent frame 0. Within a CVS, the value of **frame1_self_contained_flag** in all frame packing arrangement SEI messages shall be the same.

When **quincunx_sampling_flag** is equal to 0 and **frame_packing_arrangement_type** is not equal to 5, two (x, y) coordinate pairs are specified to determine the indicated luma sampling grid alignment for constituent frame 0 and constituent frame 1, relative to the upper left corner of the rectangular area represented by the samples of the corresponding constituent frame.

NOTE 7 – The location of chroma samples relative to luma samples can be indicated by the **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** syntax elements in the video usability information (VUI) parameters.

frame0_grid_position_x (when present) specifies the x component of the (x, y) coordinate pair for constituent frame 0.

frame0_grid_position_y (when present) specifies the y component of the (x, y) coordinate pair for constituent frame 0.

frame1_grid_position_x (when present) specifies the x component of the (x, y) coordinate pair for constituent frame 1.

frame1_grid_position_y (when present) specifies the y component of the (x, y) coordinate pair for constituent frame 1.

When **quincunx_sampling_flag** is equal to 0 and **frame_packing_arrangement_type** is not equal to 5 the (x, y) coordinate pair for each constituent frame is interpreted as follows:

- If the (x, y) coordinate pair for a constituent frame is equal to (0, 0), this indicates a default sampling grid alignment specified as follows:
 - If **frame_packing_arrangement_type** is equal to 3, the indicated position is the same as for the (x, y) coordinate pair value (4, 8), as illustrated in Figure D.4.
 - Otherwise (**frame_packing_arrangement_type** is equal to 4), the indicated position is the same as for the (x, y) coordinate pair value (8, 4), as illustrated in Figure D.6.
- Otherwise, if the (x, y) coordinate pair for a constituent frame is equal to (15, 15), this indicates that the sampling grid alignment is unknown or unspecified or specified by other means not specified in this Specification.
- Otherwise, the x and y elements of the (x, y) coordinate pair specify the indicated horizontal and vertical sampling grid alignment positioning to the right of and below the upper left corner of the rectangular area represented by the corresponding constituent frame, respectively, in units of one sixteenth of the luma sample grid spacing between the samples of the columns and rows of the constituent frame that are present in the decoded frame (prior to any upsampling for display or other purposes).

NOTE 8 – The spatial location reference information **frame0_grid_position_x**, **frame0_grid_position_y**, **frame1_grid_position_x**, and **frame1_grid_position_y** is not provided when **quincunx_sampling_flag** is equal to 1 because the spatial alignment in this case is assumed to be such that constituent frame 0 and constituent frame 1 cover corresponding spatial areas with interleaved quincunx sampling patterns as illustrated in Figure D.8.

frame_packing_arrangement_reserved_byte is reserved for future use by ITU-T | ISO/IEC. It is a requirement of bitstream conformance that the value of **frame_packing_arrangement_reserved_byte** shall be equal to 0. All other values of **frame_packing_arrangement_reserved_byte** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **frame_packing_arrangement_reserved_byte**.

frame_packing_arrangement_persistence_flag specifies the persistence of the frame packing arrangement SEI message for the current layer.

frame_packing_arrangement_persistence_flag equal to 0 specifies that the frame packing arrangement SEI message applies to the current decoded frame only.

Let **picA** be the current picture. **frame_packing_arrangement_persistence_flag** equal to 1 specifies that the frame packing arrangement SEI message persists for the current layer in output order until any of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A frame **picB** in the current layer in an access unit containing a frame packing arrangement SEI message with the same value of **frame_packing_arrangement_id** and applicable to the current layer is output for which **PicOrderCnt(picB)** is greater than **PicOrderCnt(picA)**, where **PicOrderCnt(picB)** and **PicOrderCnt(picA)** are the **PicOrderCntVal** values of **picB** and **picA**, respectively, immediately after the invocation of the decoding process for picture order count for **picB**.

upsampled_aspect_ratio_flag equal to 1 indicates that the sample aspect ratio (SAR) indicated by the VUI parameters of the SPS identifies the SAR of the samples after the application of an upconversion process to produce a higher resolution

frame from each constituent frame as illustrated in Figure D.4 to Figure D.8. `upsampled_aspect_ratio_flag` equal to 0 indicates that the SAR indicated by the VUI parameters of the SPS identifies the SAR of the samples before the application of any such upconversion process.

NOTE 9 – The default display window parameters in the VUI parameters of the SPS can be used by an encoder to indicate to a decoder that does not interpret the frame packing arrangement SEI message that the default display window is an area within only one of the two constituent frames.

NOTE 10 – The SAR indicated in the VUI parameters should indicate the preferred display picture shape for the packed decoded frame output by a decoder that does not interpret the frame packing arrangement SEI message. When `upsampled_aspect_ratio_flag` is equal to 1, the SAR produced in each up-converted colour plane is indicated to be the same as the SAR indicated in the VUI parameters in the examples shown in Figure D.4 to Figure D.8. When `upsampled_aspect_ratio_flag` is equal to 0, the SAR produced in each colour plane prior to upconversion is indicated to be the same as the SAR indicated in the VUI parameters in the examples shown in Figure D.4 to Figure D.8.

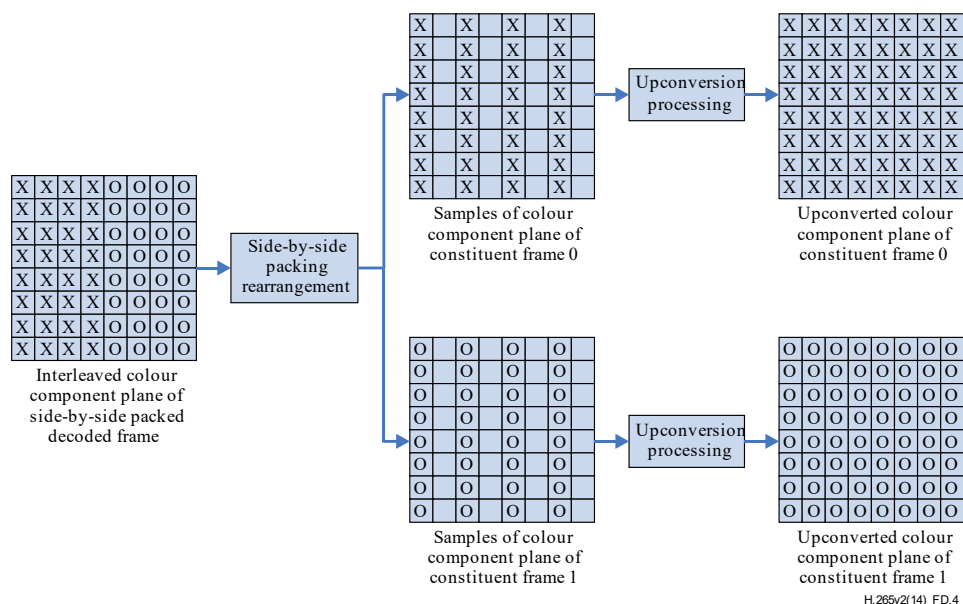

Figure D.4 – Rearrangement and upconversion of side-by-side packing arrangement with `frame_packing_arrangement_type` equal to 3, `quincunx_sampling_flag` equal to 0 and `(x, y)` equal to `(0, 0)` or `(4, 8)` for both constituent frames

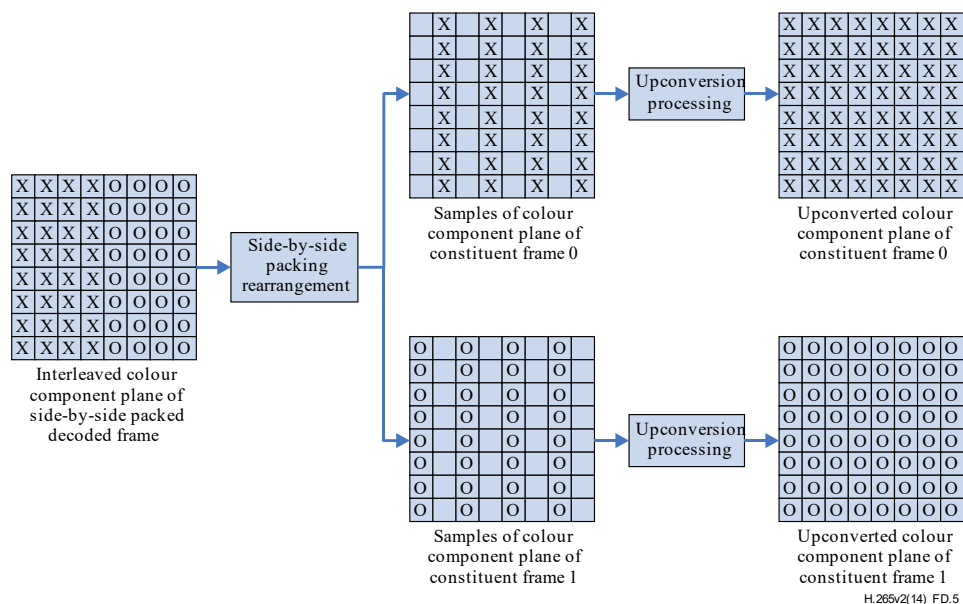

Figure D.5 – Rearrangement and upconversion of side-by-side packing arrangement with frame_packing_arrangement_type equal to 3, quincunx_sampling_flag equal to 0, (x, y) equal to (12, 8) for constituent frame 0 and (x, y) equal to (0, 0) or (4, 8) for constituent frame 1

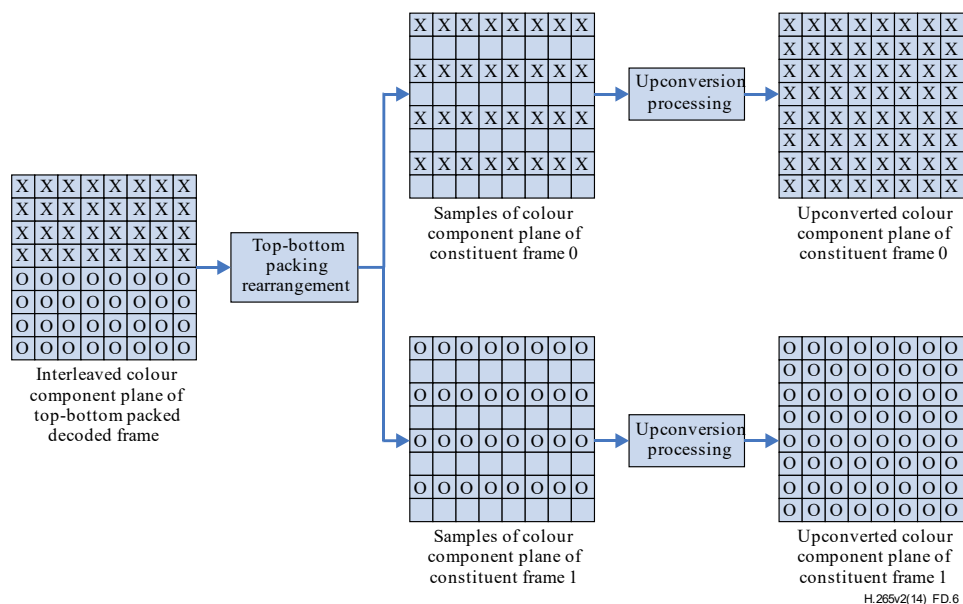

Figure D.6 – Rearrangement and upconversion of top-bottom packing arrangement with frame_packing_arrangement_type equal to 4, quincunx_sampling_flag equal to 0 and (x, y) equal to (0, 0) or (8, 4) for both constituent frames

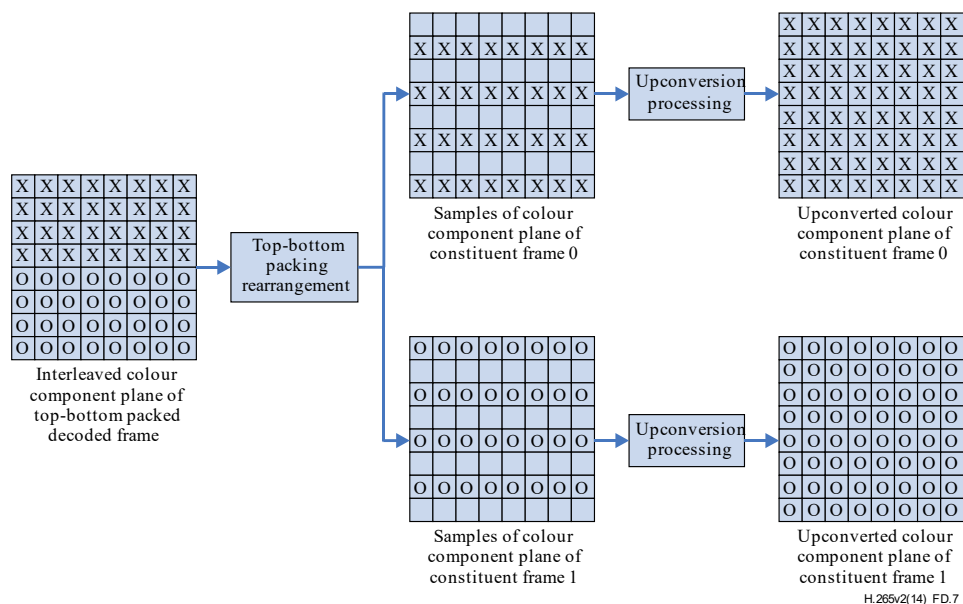

Figure D.7 – Rearrangement and upconversion of top-bottom packing arrangement with frame_packing_arrangement_type equal to 4, quincunx_sampling_flag equal to 0, (x, y) equal to (8, 12) for constituent frame 0 and (x, y) equal to (0, 0) or (8, 4) for constituent frame 1

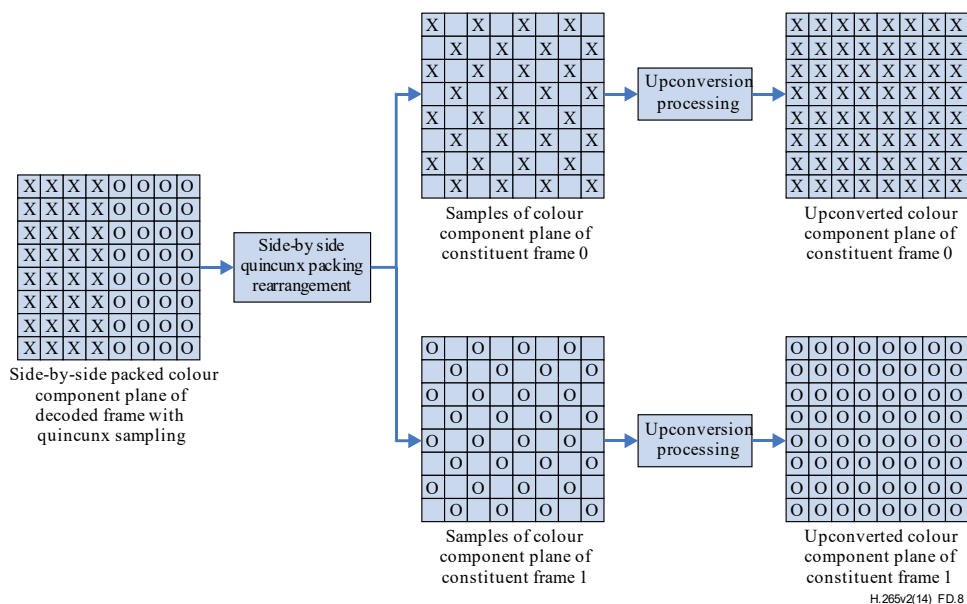

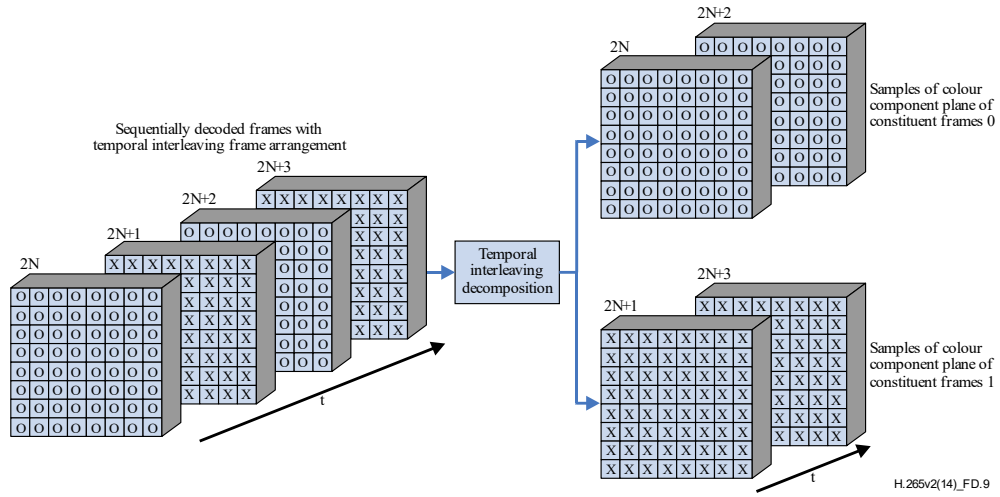

Figure D.8 – Rearrangement and upconversion of side-by-side packing arrangement with quincunx sampling (frame_packing_arrangement_type equal to 3 with quincunx_sampling_flag equal to 1)

**Figure D.9 – Rearrangement of a temporal interleaving frame arrangement
(frame_packing_arrangement_type equal to 5)**

D.3.17 Display orientation SEI message semantics

When the associated picture has PicOutputFlag equal to 1, the display orientation SEI message informs the decoder of a transformation that is recommended to be applied to the cropped decoded picture prior to display.

display_orientation_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous display orientation SEI message in output order. display_orientation_cancel_flag equal to 0 indicates that display orientation information follows.

hor_flip equal to 1 indicates that the cropped decoded picture should be flipped horizontally for display. hor_flip equal to 0 indicates that the decoded picture should not be flipped horizontally.

When hor_flip is equal to 1, the cropped decoded picture should be flipped as follows for each component Z equal to Y, Cb and Cr, letting dZ be the final cropped array of output samples for the component Z:

$$\begin{aligned} &\text{for}(x = 0; x < \text{croppedWidthZ}; x++) \\ &\quad \text{for}(y = 0; y < \text{croppedHeightZ}; y++) \\ &\quad \quad dZ[x][y] = Z[\text{croppedWidthZ} - x - 1][y] \end{aligned} \quad (\text{D-19})$$

Where croppedWidthZ is the width of the component Z of the cropped decoded picture in samples, croppedHeightZ is the height of the component Z of the cropped decoded picture in samples, and Z[x][y] and dZ[x][y] are the sample value before and after the horizontal flipping, respectively, for the sample at the location (x, y) of the component Z of the cropped decoded picture.

ver_flip equal to 1 indicates that the cropped decoded picture should be flipped vertically (in addition to any horizontal flipping when hor_flip is equal to 1) for display. ver_flip equal to 0 indicates that the decoded picture should not be flipped vertically.

When ver_flip is equal to 1, the cropped decoded picture should be flipped as follows for each component Z equal to Y, Cb and Cr, letting dZ be the final cropped array of output samples for the component Z:

$$\begin{aligned} &\text{for}(x = 0; x < \text{croppedWidthZ}; x++) \\ &\quad \text{for}(y = 0; y < \text{croppedHeightZ}; y++) \\ &\quad \quad dZ[x][y] = Z[x][\text{croppedWidthZ} - y - 1] \end{aligned} \quad (\text{D-20})$$

Where croppedWidthZ is the width of the component Z of the cropped decoded picture in samples, croppedHeightZ is the height of the component Z of the cropped decoded picture in samples, and Z[x][y] and dZ[x][y] are the sample value before and after the vertical flipping, respectively, for the sample at the location (x, y) of the component Z of the cropped decoded picture.

anticlockwise_rotation specifies the recommended anticlockwise rotation of the decoded picture (after applying horizontal or vertical flipping when hor_flip or ver_flip is set) prior to display. The decoded picture should be rotated by $360 * \text{anticlockwise_rotation} \div 2^{16}$ degrees ($2 * \pi * \text{anticlockwise_rotation} \div 2^{16}$ radians, where π is Archimedes' constant 3.141 592 653 589 793...) in the anticlockwise direction prior to display. For example, anticlockwise_rotation equal to 0

indicates no rotation and anticlockwise_rotation equal to 16 384 indicates 90 degrees ($\pi \div 2$ radians) rotation in the anticlockwise direction.

NOTE – It is possible for equivalent transformations to be expressed in multiple ways using these syntax elements. For example, the combination of having both hor_flip and ver_flip equal to 1 with anticlockwise_rotation equal to 0 can alternatively be expressed by having both hor_flip and ver_flip equal to 1 with anticlockwise_rotation equal to 0x8000, and the combination of hor_flip equal to 1 with ver_flip equal to 0 and anticlockwise_rotation equal to 0 can alternatively be expressed by having hor_flip equal to 0 with ver_flip equal to 1 and anticlockwise_rotation equal to 0x8000.

display_orientation_persistence_flag specifies the persistence of the display orientation SEI message for the current layer.

display_orientation_persistence_flag equal to 0 specifies that the display orientation SEI message applies to the current decoded picture only.

Let picA be the current picture. display_orientation_persistence_flag equal to 1 specifies that the display orientation SEI message persists for the current layer in output order until one or more of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture picB in the current layer in an access unit containing a display orientation SEI message that is applicable to the current layer is output for which PicOrderCnt(picB) is greater than PicOrderCnt(picA), where PicOrderCnt(picB) and PicOrderCnt(picA) are the PicOrderCntVal values of picB and picA, respectively, immediately after the invocation of the decoding process for picture order count for picB.

D.3.18 Green metadata SEI message semantics

The semantics for this SEI message are specified in ISO/IEC 23001-11 (Green metadata). Green metadata facilitates reduced power consumption in decoders, encoders, displays and in media selection.

D.3.19 Structure of pictures information SEI message semantics

The structure of pictures information SEI message provides information for a list of entries, some of which correspond to the target picture set that consists of a series of pictures starting from the current picture until the last picture in decoding order in the current layer in the CLVS.

The first entry in the structure of pictures information SEI message corresponds to the current picture. When there is a picture in the target picture set that has PicOrderCntVal equal to the variable entryPicOrderCnt[i] as specified below, the entry i corresponds to a picture in the target picture set. The decoding order of the pictures in the target picture set that correspond to entries in the structure of pictures information SEI message corresponds to increasing values of i in the list of entries.

Any picture picB in the target picture set that has PicOrderCntVal equal to entryPicOrderCnt[i] for any i in the range of 0 to num_entries_in_sop_minus1, inclusive, where PicOrderCntVal is the value of PicOrderCntVal of picB immediately after the invocation of the decoding process for picture order count for picB, shall correspond to an entry in the list of entries.

The structure of pictures information SEI message shall not be present in a CVS and applicable for a layer for which the active SPS has long_term_ref_pics_present_flag equal to 1 or num_short_term_ref_pic_sets equal to 0.

The structure of pictures information SEI message shall not be present in any access unit that has TemporalId greater than 0 or contains a RASL, RADL or SLNR picture in the current layer. Any picture in the target picture set that corresponds to an entry other than the first entry described in the structure of pictures information SEI message shall not be an IRAP picture.

sop_seq_parameter_set_id indicates and shall be equal to the sps_seq_parameter_set_id value of the active SPS. The value of sop_seq_parameter_set_id shall be in the range of 0 to 15, inclusive.

num_entries_in_sop_minus1 plus 1 specifies the number of entries in the structure of pictures information SEI message. num_entries_in_sop_minus1 shall be in the range of 0 to 1 023, inclusive.

sop_vcl_nut[i], when the i-th entry corresponds to a picture in the target picture set, indicates and shall be equal to the nal_unit_type value of the picture corresponding to the i-th entry.

sop_temporal_id[i], when the i-th entry corresponds to a picture in the target picture set, indicates and shall be equal to the TemporalId value of the picture corresponding to the i-th entry. The value of 7 for sop_temporal_id[i] is reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore structure of pictures information SEI messages that contain the value 7 for sop_temporal_id[i].

sop_short_term_rps_idx[i], when the i-th entry corresponds to a picture in the target picture set, indicates and shall be equal to the index, into the list of candidate short-term RPSs included in the active SPS, of the candidate short-term RPS used by the picture corresponding to the i-th entry for derivation of the short-term reference picture set. **sop_short_term_rps_idx**[i] shall be in the range of 0 to **num_short_term_ref_pic_sets** – 1, inclusive.

sop_poc_delta[i] is used to specify the value of the variable **entryPicOrderCnt**[i] for the i-th entry described in the structure of pictures information SEI message. **sop_poc_delta**[i] shall be in the range of (–**MaxPicOrderCntLsb**) / 2 + 1 to **MaxPicOrderCntLsb** / 2 – 1, inclusive.

The variable **entryPicOrderCnt**[i] is derived as follows:

$$\begin{aligned} \text{entryPicOrderCnt}[0] &= \text{PicOrderCnt}(\text{currPic}) \\ \text{for}(i = 1; i \leq \text{num_entries_in_sop_minus1}; i++) \\ \quad \text{entryPicOrderCnt}[i] &= \text{entryPicOrderCnt}[i - 1] + \text{sop_poc_delta}[i] \end{aligned} \quad (\text{D-21})$$

where **currPic** is the current picture.

D.3.20 Decoded picture hash SEI message semantics

This message provides a hash for each colour component of the current decoded picture.

NOTE 1 – The decoded picture hash SEI message is a suffix SEI message and cannot be contained in a scalable nesting SEI message.

Prior to computing the hash, the decoded picture data are arranged into one or three strings of bytes called **pictureData**[cIdx] of lengths **dataLen**[cIdx] as follows:

$$\begin{aligned} &\text{for}(cIdx = 0; cIdx < (\text{chroma_format_idc} == 0) ? 1 : 3; cIdx++) \{ \\ &\quad \text{if}(cIdx == 0) \{ \\ &\quad \quad \text{compWidth}[cIdx] = \text{pic_width_in_luma_samples} \\ &\quad \quad \text{compHeight}[cIdx] = \text{pic_height_in_luma_samples} \\ &\quad \quad \text{compDepth}[cIdx] = \text{BitDepth}_Y \\ &\quad \} \text{ else } \{ \\ &\quad \quad \text{compWidth}[cIdx] = \text{pic_width_in_luma_samples} / \text{SubWidthC} \\ &\quad \quad \text{compHeight}[cIdx] = \text{pic_height_in_luma_samples} / \text{SubHeightC} \\ &\quad \quad \text{compDepth}[cIdx] = \text{BitDepth}_C \\ &\quad \} \\ &\quad iLen = 0 \\ &\quad \text{for}(i = 0; i < \text{compWidth}[cIdx] * \text{compHeight}[cIdx]; i++) \{ \\ &\quad \quad \text{pictureData}[cIdx][iLen++] = \text{component}[cIdx][i] \& 0xFF \\ &\quad \quad \text{if}(\text{compDepth}[cIdx] > 8) \\ &\quad \quad \quad \text{pictureData}[cIdx][iLen++] = \text{component}[cIdx][i] >> 8 \\ &\quad \} \\ &\quad \text{dataLen}[cIdx] = iLen \\ &\} \end{aligned} \quad (\text{D-22})$$

where **component**[cIdx][i] is an array in raster scan of decoded sample values in two's complement representation.

hash_type indicates the method used to calculate the checksum according to Table D.10. Values of **hash_type** that are not listed in Table D.10 are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore decoded picture hash SEI messages that contain reserved values of **hash_type**.

Table D.10 – Interpretation of hash_type

hash_type	Method
0	MD5 (IETF RFC 1321)
1	CRC
2	Checksum

picture_md5[cIdx][i] is the 16-byte MD5 hash of the cIdx-th colour component of the decoded picture. The value of **picture_md5**[cIdx][i] shall be equal to the value of **digestVal**[cIdx] obtained as follows, using the MD5 functions defined in IETF RFC 1321:

```

MD5Init( context )
MD5Update( context, pictureData[ cIdx ], dataLen[ cIdx ] )
MD5Final( digestVal[ cIdx ], context )

```

(D-23)

picture_crc[cIdx] is the cyclic redundancy check (CRC) of the colour component cIdx of the decoded picture. The value of picture_crc[cIdx] shall be equal to the value of crcVal[cIdx] obtained as follows:

```

crc = 0xFFFF
pictureData[ cIdx ][ dataLen[ cIdx ] ] = 0
pictureData[ cIdx ][ dataLen[ cIdx ] + 1 ] = 0
for( bitIdx = 0; bitIdx < ( dataLen[ cIdx ] + 2 ) * 8; bitIdx++ ) {
    dataByte = pictureData[ cIdx ][ bitIdx >> 3 ]
    crcMsb = ( crc >> 15 ) & 1
    bitVal = ( dataByte >> ( 7 - ( bitIdx & 7 ) ) ) & 1
    crc = ( ( ( crc << 1 ) + bitVal ) & 0xFFFF ) ^ ( crcMsb * 0x1021 )
}
crcVal[ cIdx ] = crc

```

(D-24)

NOTE 2 – The same CRC specification is found in Rec. ITU-T H.271.

picture_checksum[cIdx] is the checksum of the colour component cIdx of the decoded picture. The value of picture_checksum[cIdx] shall be equal to the value of checksumVal[cIdx] obtained as follows:

```

sum = 0
for( y = 0; y < compHeight[ cIdx ]; y++ )
    for( x = 0; x < compWidth[ cIdx ]; x++ ) {
        xorMask = ( x & 0xFF ) ^ ( y & 0xFF ) ^ ( x >> 8 ) ^ ( y >> 8 )
        sum = ( sum + ( ( component[ cIdx ][ y * compWidth[ cIdx ] + x ] & 0xFF ) ^ xorMask ) )
        &
        0xFFFFFFFF

```

(D-25)

D.3.21 Active parameter sets SEI message semantics

The active parameter sets SEI message indicates which VPS is active for the VCL NAL units of the access unit associated with the SEI message. The SEI message may also provide information on which SPS is active for the VCL NAL units of the access unit associated with the SEI message and other information related to parameter sets.

active_video_parameter_set_id indicates and shall be equal to the value of the vps_video_parameter_set_id of the VPS that is referred to by the VCL NAL units of the access unit associated with the SEI message. The value of active_video_parameter_set_id shall be in the range of 0 to 15, inclusive.

self_contained_cvs_flag equal to 1 indicates that each parameter set that is (directly or indirectly) referenced by any VCL NAL unit of the CVS that is not a VCL NAL unit of a RASL picture is present within the CVS at a position that precedes, in decoding order, any NAL unit that (directly or indirectly) references the parameter set. self_contained_cvs_flag equal to 0 indicates that this property may or may not apply.

no_parameter_set_update_flag equal to 1 indicates that there is no parameter set update in the CVS, i.e., each VPS in the CVS is an exact copy of the previous VPS in decoding order in the bitstream that has the same value of vps_video_parameter_set_id, when present; each SPS in the CVS is an exact copy of the previous SPS in decoding order in the bitstream that has the same value of sps_seq_parameter_set_id, when present; and each PPS in the CVS is an exact copy of the previous PPS in decoding order in the bitstream that has the same value of pps_pic_parameter_set_id, when present. no_parameter_set_update_flag equal to 0 indicates that there may or may not be parameter set update in the CVS.

NOTE 1 – If no_parameter_set_update_flag equal to 1 is indicated for each CVS in a bitstream, i.e., there is no parameter set update in the bitstream, it is possible to transmit all parameter sets out-of-band before sending the first VCL NAL unit of the bitstream or to place all parameter sets at the beginning of the bitstream. Otherwise, out-of-band transmission of all parameter sets before sending VCL NAL units is not possible.

num_sps_ids_minus1 plus 1 shall be less than or equal to the number of SPSs that are referred to by the VCL NAL units of the access unit associated with the active parameter sets SEI message. The value of **num_sps_ids_minus1** shall be in the range of 0 to 15, inclusive.

active_seq_parameter_set_id[*i*] indicates a value of the **sps_seq_parameter_set_id** of the SPS that may be referred to by any VCL NAL unit of the access unit associated with the SEI message. When **vps_base_layer_internal_flag** is equal to 1 and **vps_base_layer_available_flag** is equal to 1, **active_seq_parameter_set_id**[0] indicates and shall be equal to the value of the **sps_seq_parameter_set_id** of the SPS that is referred to by the VCL NAL units with **nuh_layer_id** equal to 0 in the access unit associated with the SEI message. The value of **active_seq_parameter_set_id**[*i*] shall be in the range of 0 to 15, inclusive.

layer_sps_idx[*i*] indicates that the **sps_seq_parameter_set_id** value of the SPS that is referred to by the VCL NAL units with **nuh_layer_id** equal to **layer_id_in_nuh**[*i*] in the access unit associated with the SEI message, if any, is equal to **active_seq_parameter_set_id**[**layer_sps_idx**[*i*]].

NOTE 2 – When decoding a single-layer bitstream or only the base layer of a multi-layer bitstream, the decoder does not need to parse **layer_sps_idx**[*i*] syntax elements, because they do not affect the decoding of the base layer.

D.3.22 Decoding unit information SEI message semantics

The decoding unit information SEI message provides CPB removal delay information for the decoding unit associated with the SEI message.

When the buffering period SEI message is non-scalable-nested or is directly contained in a scalable nesting SEI message within an SEI NAL unit with **nuh_layer_id** equal to 0, the following applies for the decoding unit information SEI message syntax and semantics:

- The syntax elements **sub_pic_hrd_params_present_flag**, **sub_pic_cpb_params_in_pic_timing_sei_flag** and **dpb_output_delay_du_length_minus1**, and the variable **CpbDpbDelaysPresentFlag** are found in or derived from syntax elements in the **hrd_parameters()** syntax structure that is applicable to at least one of the operation points to which the decoding unit information SEI message applies.
- The bitstream (or a part thereof) refers to the bitstream subset (or a part thereof) associated with any of the operation points to which the decoding unit information SEI message applies.

The presence of decoding unit information SEI messages for an operation point including the base layer is specified as follows:

- If **CpbDpbDelaysPresentFlag** is equal to 1, **sub_pic_hrd_params_present_flag** is equal to 1 and **sub_pic_cpb_params_in_pic_timing_sei_flag** is equal to 0, one or more decoding unit information SEI messages applicable to the operation point shall be associated with each decoding unit in the CVS.
- Otherwise, if **CpbDpbDelaysPresentFlag** is equal to 1, **sub_pic_hrd_params_present_flag** is equal to 1 and **sub_pic_cpb_params_in_pic_timing_sei_flag** is equal to 1, one or more decoding unit information SEI messages applicable to the operation point may or may not be associated with each decoding unit in the CVS.
- Otherwise (**CpbDpbDelaysPresentFlag** is equal to 0 or **sub_pic_hrd_params_present_flag** is equal to 0), in the CVS there shall be no decoding unit that is associated with a decoding unit information SEI message applicable to the operation point.

When the buffering period SEI message is non-scalable-nested or is directly contained in a scalable nesting SEI message within an SEI NAL unit with **nuh_layer_id** equal to 0, the set of NAL units associated with a decoding unit information SEI message consists, in decoding order, of the SEI NAL unit containing the decoding unit information SEI message and all subsequent NAL units in the access unit up to but not including any subsequent SEI NAL unit containing a decoding unit information SEI message with a different value of **decoding_unit_idx**. Each decoding unit shall include at least one VCL NAL unit. All non-VCL NAL units associated with a VCL NAL unit shall be included in the decoding unit containing the VCL NAL unit.

decoding_unit_idx specifies the index, starting from 0, to the list of decoding units in the current access unit, of the decoding unit associated with the decoding unit information SEI message. The value of **decoding_unit_idx** shall be in the range of 0 to **PicSizeInCtbsY** – 1, inclusive.

A decoding unit identified by a particular value of **duIdx** includes and only includes all NAL units associated with all decoding unit information SEI messages that have **decoding_unit_idx** equal to **duIdx**. Such a decoding unit is also referred to as associated with the decoding unit information SEI messages having **decoding_unit_idx** equal to **duIdx**.

For any two decoding units **duA** and **duB** in one access unit with **decoding_unit_idx** equal to **duIdxA** and **duIdxB**, respectively, where **duIdxA** is less than **duIdxB**, **duA** shall precede **duB** in decoding order.

A NAL unit of one decoding unit shall not be present, in decoding order, between any two NAL units of another decoding unit.

du_spt_cpb_removal_delay_increment specifies the duration, in units of clock sub-ticks, between the nominal CPB times of the last decoding unit in decoding order in the current access unit and the decoding unit associated with the decoding unit information SEI message. This value is also used to calculate an earliest possible time of arrival of decoding unit data into the CPB for the HSS, as specified in Annex C or clause F.13. The syntax element is represented by a fixed length code whose length in bits is given by `du_cpb_removal_delay_increment_length_minus1 + 1`. When the decoding unit associated with the decoding unit information SEI message is the last decoding unit in the current access unit, the value of `du_spt_cpb_removal_delay_increment` shall be equal to 0.

dpb_output_du_delay_present_flag equal to 1 specifies the presence of the `pic_spt_dpb_output_du_delay` syntax element in the decoding unit information SEI message. `dpb_output_du_delay_present_flag` equal to 0 specifies the absence of the `pic_spt_dpb_output_du_delay` syntax element in the decoding unit information SEI message.

pic_spt_dpb_output_du_delay is used to compute the DPB output time of the picture when `SubPicHrdFlag` is equal to 1. It specifies how many sub clock ticks to wait after removal of the last decoding unit in an access unit from the CPB before the decoded picture is output from the DPB. When not present, the value of `pic_spt_dpb_output_du_delay` is inferred to be equal to `pic_dpb_output_du_delay`.

The length of the syntax element `pic_spt_dpb_output_du_delay` is given in bits by `dpb_output_delay_du_length_minus1 + 1`.

When the buffering period SEI message is non-scalable-nested or is directly contained in a scalable nesting SEI message within an SEI NAL unit with `nuh_layer_id` equal to 0, it is a requirement of bitstream conformance that all decoding unit information SEI messages that are associated with the same access unit, apply to the same operation point, and have `dpb_output_du_delay_present_flag` equal to 1 shall have the same value of `pic_spt_dpb_output_du_delay`.

The output time derived from the `pic_spt_dpb_output_du_delay` of any picture that is output from an output timing conforming decoder shall precede the output time derived from the `pic_spt_dpb_output_du_delay` of all pictures in any subsequent CVS in decoding order.

The picture output order established by the values of this syntax element shall be the same order as established by the values of `PicOrderCntVal`.

For pictures that are not output by the "bumping" process because they precede, in decoding order, an IRAP picture with `NoRaslOutputFlag` equal to 1 that has `no_output_of_prior_pics_flag` equal to 1 or inferred to be equal to 1, the output times derived from `pic_spt_dpb_output_du_delay` shall be increasing with increasing value of `PicOrderCntVal` relative to all pictures within the same CVS.

For any two pictures in the CVS, the difference between the output times of the two pictures when `SubPicHrdFlag` is equal to 1 shall be identical to the same difference when `SubPicHrdFlag` is equal to 0.

D.3.23 Temporal sub-layer zero index SEI message semantics

The temporal sub-layer zero index SEI message provides information that can assist the decoder for detection of missing coded pictures that have `TemporalId` equal to 0 and are not RASL, RADL or SLNR pictures.

When a temporal sub-layer zero index SEI message is present in the current access unit and applies to the current layer and the current picture is not an IRAP picture, a temporal sub-layer zero index SEI message that applies to the current layer shall also be present in the preceding access unit in decoding order with `TemporalId` equal to 0 and containing a picture that is not a RASL, RADL or SLNR picture in the current layer.

NOTE – Encoders should be cautious when setting `discardable_flag` equal to 1 for any picture with `TemporalId` equal to 0, as based on temporal sub-layer zero index SEI messages decoders may consider intentionally discarded pictures with `TemporalId` equal to 0 and `discardable_flag` equal to 1 as lost and take unnecessary error recovery actions, such as requesting retransmission of a missing picture with `TemporalId` equal to 0.

Let `ReferencedTsl0Pic` denote a picture that has `TemporalId` equal to 0 and is not a RASL, RADL or SLNR picture.

temporal_sub_layer_zero_idx indicates a temporal sub-layer zero index as follows:

- If the current picture is a `ReferencedTsl0Pic`, `temporal_sub_layer_zero_idx` indicates the temporal sub-layer zero index for the current picture.
- Otherwise, `temporal_sub_layer_zero_idx` indicates the temporal sub-layer zero index of the preceding picture in the current layer in decoding order that is a `ReferencedTsl0Pic`.

When the bitstream contains a preceding access unit in decoding order that contained a `ReferencedTsl0Pic`, and that preceding access unit has an associated temporal sub-layer zero index SEI message `seiMsgB` that applies to the current layer, the variable `prevTsl0Idx` is set equal to the value of `temporal_sub_layer_zero_idx` of `seiMsgB`.

The following constraints apply to the value of `temporal_sub_layer_zero_idx`:

- If the current picture is an IRAP picture, `temporal_sub_layer_zero_idx` shall be equal to 0.

- Otherwise, the following applies:
 - If the current picture is a ReferencedTsl0Pic, temporal_sub_layer_zero_idx shall be equal to $(\text{prevTsl0Idx} + 1) \% 256$.
 - Otherwise, temporal_sub_layer_zero_idx shall be equal to prevTsl0Idx.

irap_pic_id is an IRAP picture identifier for the current layer. When the current picture is not the first picture in the current layer in the bitstream in decoding order and the preceding IRAP picture in the current layer in decoding order has an associated temporal sub-layer zero index SEI message, the following constraints apply to the value of irap_pic_id:

- If the current picture is an IRAP picture, irap_pic_id shall differ in value from the value of irap_pic_id of the temporal sub-layer zero index SEI message of the preceding IRAP picture in the current layer in decoding order.

NOTE – It is suggested for the value of irap_pic_id to be set to a random value (subject to the constraints specified herein), to minimize the likelihood of duplicate values appearing in a layer in the bitstream due to picture losses or splicing operations.
- Otherwise, irap_pic_id shall be equal to the value of irap_pic_id of the temporal sub-layer zero index SEI message associated with the preceding IRAP picture in the current layer in decoding order.

D.3.24 Scalable nesting SEI message semantics

The scalable nesting SEI message provides a mechanism to associate SEI messages with bitstream subsets corresponding to various operation points or with specific layers or sub-layers.

A scalable nesting SEI message contains one or more SEI messages.

NOTE – A scalable nesting SEI message can only be the last SEI message in the SEI NAL unit containing the scalable nesting SEI message. The sei_payload() of the scalable nesting SEI message cannot contain any reserved_payload_extension_data.

It is a requirement of bitstream conformance that the following restrictions apply on containing of SEI messages in a scalable nesting SEI message:

- An SEI message that has payloadType equal to 129 (active parameter sets), 132 (decoded picture hash) or 133 (scalable nesting) shall not be contained in a scalable nesting SEI message.
- When a scalable nesting SEI message contains a buffering period SEI message, a picture timing SEI message or a decoding unit information SEI message, the scalable nesting SEI message shall not contain any other SEI message with payloadType not equal to 0 (buffering period), 1 (picture timing) or 130 (decoding unit information).

bitstream_subset_flag equal to 0 specifies that the SEI messages contained in the scalable nesting SEI message apply to specific layers or sub-layers. bitstream_subset_flag equal to 1 specifies that the SEI messages contained in the scalable nesting SEI message apply to one or more sub-bitstreams as specified below.

Depending on the value of bitstream_subset_flag, the layers or sub-layers, or the operation points to which the SEI messages contained in the scalable nesting SEI message apply are specified by deriving the lists nestingLayerIdList[i] and the variables MaxTemporalId[i] based on syntax element values as specified below.

It is a requirement of bitstream conformance that the following restrictions apply on the value of bitstream_subset_flag:

- When the scalable nesting SEI message contains a buffering period SEI message, a picture timing SEI message or a decoding unit information SEI message, bitstream_subset_flag shall be equal to 1.
- When the scalable nesting SEI message contains an SEI message that has payloadType equal to any value among SingleLayerSeiList, bitstream_subset_flag shall be equal to 0.

nesting_op_flag equal to 0 specifies that the list nestingLayerIdList[0] is specified by all_layers_flag and, when present, nesting_layer_id[i] for all i values in the range of 0 to nesting_num_layers_minus1, inclusive, and that the variable MaxTemporalId[0] is specified by nesting_no_op_max_temporal_id_plus1. nesting_op_flag equal to 1 specifies that the list nestingLayerIdList[i] and the variable MaxTemporalId[i] are specified by nesting_num_ops_minus1, default_op_flag, nesting_max_temporal_id_plus1[i], when present, and nesting_op_idx[i], when present.

default_op_flag equal to 1 specifies that MaxTemporalId[0] is equal to nuh_temporal_id_plus1 of the current SEI NAL unit minus 1 and that nestingLayerIdList[0] contains all integer values in the range of 0 to nuh_layer_id of the current SEI NAL unit, inclusive, in increasing order of the values.

nesting_num_ops_minus1 plus 1 minus default_op_flag specifies the number of the following nesting_op_idx[i] syntax elements. The value of nesting_num_ops_minus1 shall be in the range of 0 to 1 023, inclusive.

If nesting_op_flag is equal to 0, the variable nestingNumOps is set equal to 1. Otherwise, the variable nestingNumOps is set equal to nesting_num_ops_minus1 + 1.

nesting_max_temporal_id_plus1[*i*] is used to specify the variable **MaxTemporalId**[*i*]. The value of **nesting_max_temporal_id_plus1**[*i*] shall be greater than or equal to **nuh_temporal_id_plus1** of the current SEI NAL unit. The variable **MaxTemporalId**[*i*] is set equal to **nesting_max_temporal_id_plus1**[*i*] – 1.

nesting_op_idx[*i*] is used to specify the list **nestingLayerIdList**[*i*]. The value of **nesting_op_idx**[*i*] shall be in the range of 0 to 1 023, inclusive.

The list **nestingLayerIdList**[*i*] is set equal to the **OpLayerIdList** of the **nesting_op_idx**[*i*]-th layer set specified by the active VPS.

It is a requirement of bitstream conformance that when **nesting_op_flag** is equal to 1 and **nesting_op_idx**[*i*] is greater than **vps_num_layer_sets_minus1** for any value of *i* in the range of **default_op_flag** to **nesting_num_ops_minus1**, inclusive, the value of **nuh_layer_id** of the SEI NAL unit containing the scalable nesting SEI message shall be greater than 0.

all_layers_flag equal to 0 specifies that the list **nestingLayerIdList**[0] is specified by **nesting_layer_id**[*i*] for all *i* values in the range of 0 to **nesting_num_layers_minus1**, inclusive. **all_layers_flag** equal to 1 specifies that the list **nestingLayerIdList**[0] consists of all values of **nuh_layer_id** present in the current access unit that are greater than or equal to **nuh_layer_id** of the current SEI NAL unit, in increasing order of the values.

When **nesting_op_flag** is equal to 0 and **all_layers_flag** is equal to 1, **MaxTemporalId**[0] is set equal to 6.

nesting_no_op_max_temporal_id_plus1 minus 1 specifies the value of **MaxTemporalId**[0] when **nesting_op_flag** is equal to 0 and **all_layers_flag** is equal to 0. The value of **nesting_no_op_max_temporal_id_plus1** shall not be equal to 0.

nesting_num_layers_minus1 plus 1 specifies the number of the following **nesting_layer_id**[*i*] syntax elements. The value of **nesting_num_layers_minus1** shall be in the range of 0 to 63, inclusive.

nesting_layer_id[*i*] specifies the *i*-th **nuh_layer_id** value included in the list **nestingLayerIdList**[0].

For any *i* and *j* in the range of 0 to **nesting_num_layers_minus1**, inclusive, with *i* less than *j*, **nesting_layer_id**[*i*] shall be less than **nesting_layer_id**[*j*].

The list **nestingLayerIdList**[0] is set to consist of **nesting_layer_id**[*i*] for all *i* values in the range of 0 to **nesting_num_layers_minus1**, inclusive, in increasing order of *i* values.

When **bitstream_subset_flag** is equal to 0, the following applies:

- The SEI messages contained in the scalable nesting SEI message apply to the sets of layers or sub-layers **subLayerSet**[*i*] for all *i* values in the range of 0 to **nestingNumOps** – 1, inclusive, where the VCL NAL units of the layers or sub-layers in each set **subLayerSet**[*i*] have **nuh_layer_id** values that are included in the list **nestingLayerIdList**[*i*] and **TemporalId** values that are in the range of the **TemporalId** of the current SEI NAL unit to **MaxTemporalId**[*i*], inclusive.
- When a scalable-nested SEI message has **payloadType** equal to any value among **VclAssociatedSeiList**, the value of **TemporalId** of the SEI NAL unit containing the scalable nesting SEI message shall be equal to 0 and **MaxTemporalId**[*i*] for all values of *i* in the range of 0 to **nestingNumOps** – 1, inclusive, shall be equal to 6.
- When a scalable-nested SEI message has **payloadType** equal to any value among **VclAssociatedSeiList** and the value of **nestingNumOps** is greater than 0, the scalable-nested SEI message applies to all layers for which each **nuh_layer_id** is included in at least one of the lists **nestingLayerIdList**[*i*] with *i* ranging from 0 to **nestingNumOps** – 1, inclusive.

When **bitstream_subset_flag** is equal to 1, the SEI messages contained in the scalable nesting SEI message apply to the operation points corresponding to the sub-bitstreams **subBitstream**[*i*] for all *i* values in the range of 0 to **nestingNumOps** – 1, inclusive, where each sub-bitstream **subBitstream**[*i*] is derived as follows:

- If **nestingLayerIdList**[*i*][0] is equal to 0 and **vps_base_layer_internal_flag** is equal to 1, the sub-bitstream **subBitstream**[*i*] is the output of the sub-bitstream extraction process of clause 10 with the bitstream, **MaxTemporalId**[*i*] and **nestingLayerIdList**[*i*] as inputs.
- Otherwise, if **nestingLayerIdList**[*i*][0] is equal to 0 and **vps_base_layer_internal_flag** is equal to 0, the sub-bitstream **subBitstream**[*i*] is the output of the sub-bitstream extraction process of clause F.10.1 with the bitstream, **MaxTemporalId**[*i*] and **nestingLayerIdList**[*i*] as inputs.
- Otherwise, the sub-bitstream **subBitstream**[*i*] is the output of the sub-bitstream extraction process of clause F.10.3 with the bitstream, **MaxTemporalId**[*i*] and **nestingLayerIdList**[*i*] as inputs.

nesting_zero_bit shall be equal to 0.

D.3.25 Region refresh information SEI message semantics

The region refresh information SEI message indicates whether the slice segments that the current SEI message applies to belong to a refreshed region of the current picture (as defined below).

An access unit that is not an IRAP access unit and that contains a recovery point SEI message is referred to as a gradual decoding refresh (GDR) access unit, and its corresponding picture is referred to as a GDR picture. The access unit corresponding to the indicated recovery point picture is referred to as the recovery point access unit.

If there is a picture that follows the GDR picture in decoding order in the CVS and that has `PicOrderCntVal` equal to the `PicOrderCntVal` of the GDR picture plus the value of `recovery_poc_cnt` in the recovery point SEI message, let the variable `lastPicInSet` be the recovery point picture. Otherwise, let `lastPicInSet` be the picture that immediately precedes the recovery point picture in output order. The picture `lastPicInSet` shall not precede the GDR picture in decoding order.

Let `gdrPicSet` be the set of pictures starting from a GDR picture to the picture `lastPicInSet`, inclusive, in output order. When the decoding process is started from a GDR access unit, the refreshed region in each picture of the `gdrPicSet` is indicated to be the region of the picture that is correct or approximately correct in content, and, when `lastPicInSet` is the recovery point picture, the refreshed region in `lastPicInSet` covers the entire picture.

The slice segments to which a region refresh information SEI message applies consist of all slice segments within the access unit that follow the SEI NAL unit containing the region refresh information SEI message and precede the next SEI NAL unit containing a region refresh information SEI message (if any) in decoding order. These slice segments are referred to as the slice segments associated with the region refresh information SEI message.

Let `gdrAuSet` be the set of access units corresponding to `gdrPicSet`. A `gdrAuSet` and the corresponding `gdrPicSet` are referred to as being associated with the recovery point SEI message contained in the GDR access unit.

Region refresh information SEI messages shall not be present in an access unit unless the access unit is included in a `gdrAuSet` associated with a recovery point SEI message. When any access unit that is included in a `gdrAuSet` contains one or more region refresh information SEI messages, all access units in the `gdrAuSet` shall contain one or more region refresh information SEI messages.

refreshed_region_flag equal to 1 indicates that the slice segments associated with the current SEI message belong to the refreshed region in the current picture. **refreshed_region_flag** equal to 0 indicates that the slice segments associated with the current SEI message may not belong to the refreshed region in the current picture.

When one or more region refresh information SEI messages are present in an access unit and the first slice segment of the access unit in decoding order does not have an associated region refresh information SEI message, the value of **refreshed_region_flag** for the slice segments that precede the first region refresh information SEI message is inferred to be equal to 0.

When `lastPicInSet` is the recovery point picture, and any region refresh SEI message is included in a recovery point access unit, the first slice segment of the access unit in decoding order shall have an associated region refresh SEI message, and the value of **refreshed_region_flag** shall be equal to 1 in all region refresh SEI messages in the access unit.

When one or more region refresh information SEI messages are present in an access unit, the refreshed region in the picture is specified as the set of CTUs in all slice segments of the access unit that are associated with region refresh information SEI messages that have **refreshed_region_flag** equal to 1. Other slice segments belong to the non-refreshed region of the picture.

It is a requirement of bitstream conformance that when a dependent slice segment belongs to the refreshed region, the preceding slice segment in decoding order shall also belong to the refreshed region.

Let `gdrRefreshedSliceSegmentSet` be the set of all slice segments that belong to the refreshed regions in the `gdrPicSet`. When a `gdrAuSet` contains one or more region refresh information SEI messages, it is a requirement of bitstream conformance that the following constraints all apply:

- The refreshed region in the first picture included in the corresponding `gdrPicSet` in decoding order that contains any refreshed region shall contain only coding units that are coded in an intra coding mode.
- For each picture included in the `gdrPicSet`, the syntax elements in `gdrRefreshedSliceSegmentSet` shall be constrained such that no samples or motion vector values outside of `gdrRefreshedSliceSegmentSet` are used for inter prediction in the decoding process of any samples within `gdrRefreshedSliceSegmentSet`.
- For any picture that follows the picture `lastPicInSet` in output order, the syntax elements in the slice segments of the picture shall be constrained such that no samples or motion vector values outside of `gdrRefreshedSliceSegmentSet` are used for inter prediction in the decoding process of the picture other than those of the other pictures that follow the picture `lastPicInSet` in output order.

reserved_sei_message_payload_byte is a byte reserved for future use by ITU-T | ISO/IEC.

D.3.26 No display SEI message semantics

The no display SEI message indicates that the current picture should not be displayed.

D.3.27 Time code SEI message semantics

The time code SEI message provides time code information similar to that defined by SMPTE ST 12-1 (2014) for field(s) or frame(s) of the current picture. When `vps_timing_info_present_flag` is equal to 1, it also defines a time offset for use in calculating a reference clock timestamp from the time code syntax elements to indicate a time of origin, capture, or alternative ideal display.

num_clock_ts specifies the number of sets of clock timestamp syntax elements that may be present for the current picture, the presence of each of which is specified by a syntax flag `clock_timestamp_flag[i]` for a corresponding value of *i*. When `frame_field_info_present_flag` is equal to 1, the *i*-th set of clock timestamp syntax elements applies to the *i*-th field or frame associated with the indicated display of the current picture in the order specified by `pic_struct` in Table D.2. The value of `num_clock_ts` shall not be equal to 0.

When `field_seq_flag` is equal to 1, the value of `num_clock_ts` shall be equal to 1.

When `frame_field_info_present_flag` is equal to 1, the value of `num_clock_ts` shall be equal to the value of `DeltaToDivisor` specified in Table E.7.

When `vps_timing_info_present_flag` is equal to 1, the contents of the clock timestamp syntax elements indicate a time of origin, capture, or alternative ideal display. This indicated time is computed as

$$\text{clockTimestamp}[i] = ((\text{hH} * 60 + \text{mM}) * 60 + \text{sS}) * \text{vui_time_scale} + \text{nFrames} * (\text{vui_num_units_in_tick} * (1 + \text{units_field_based_flag}[i])) + \text{tOffset} \quad (\text{D-26})$$

in units of clock ticks of a clock with clock frequency equal to `vui_time_scale` Hz, relative to some unspecified point in time for which `clockTimestamp[i]` would be equal to 0. Output order and DPB output timing are not affected by the value of `clockTimestamp[i]`. When `frame_field_info_present_flag` is equal to 1 and two or more pictures with `pic_struct` equal to 0 are consecutive in output order and have equal values of `clockTimestamp[i]`, the indication is that the pictures represent the same content and that the last such picture in output order is the preferred representation.

NOTE 1 – `clockTimestamp[i]` time indications may aid display on devices with refresh rates other than those well-matched to DPB output times. However, the time code SEI message does not affect the output order and DPB output timing defined in this Specification.

clock_timestamp_flag[i] equal to 1 indicates that associated set of clock timestamp syntax elements are present for the *i*-th set of clock timestamp syntax elements of the current picture. `clock_timestamp_flag[i]` equal to 0 indicates that the associated set of clock timestamp syntax elements is not present. When `vps_timing_info_present_flag` is equal to 1, `num_clock_ts` is greater than 1 and `clock_timestamp_flag[i]` is equal to 1 for more than one value of *i*, the value of `clockTimestamp[i]` shall be non-decreasing with increasing value of *i*.

For the *i*-th set of clock timestamp syntax elements of the current picture, the previous set of clock timestamp syntax elements in decoding order (or in output order, respectively), is defined as follows:

- If *i* is equal to 0, the previous set of clock timestamp syntax elements in decoding order (or in output order, respectively) is the set of syntax elements for the highest value of *i* for the previous picture in decoding order (or in output order, respectively) that contained a time code SEI message.
- Otherwise, the previous set of clock timestamp syntax elements in decoding order (or in output order, respectively) is the (*i* – 1)-th set of clock timestamp syntax elements of the current picture.

units_field_based_flag[i] is used in calculating `clockTimestamp[i]`, as specified in Equation D-26.

NOTE 2 – `units_field_based_flag[i]` should be the same for all values of *i* for all pictures in the CVS. When `field_seq_flag` is equal to 1 or `frame_field_info_present_flag` is equal to 1 and `pic_struct` is in the range of 1 to 6 or 9 to 12, inclusive, `units_field_based_flag[i]` should be equal to 1.

counting_type[i] specifies the method of dropping values of the `n_frames[i]` syntax element as specified in Table D.11.

NOTE 3 – `counting_type[i]` should be the same for all values of *i* for all pictures in the CVS.

Table D.11 – Definition of `counting_type[i]` values

Value	Interpretation
-------	----------------

0	No dropping of $n_frames[i]$ count values and no use of $time_offset_value[i]$
1	No dropping of $n_frames[i]$ count values
2	Dropping of individual zero values of $n_frames[i]$ count
3	Dropping of individual values of $n_frames[i]$ count equal to $MaxFPS - 1$
4	Dropping of the two lowest (value 0 and 1) $n_frames[i]$ counts when $seconds_value[i]$ is equal to 0 and $minutes_value[i]$ is not an integer multiple of 10
5	Dropping of unspecified individual $n_frames[i]$ count values
6	Dropping of unspecified numbers of unspecified $n_frames[i]$ count values
7..31	Reserved

full_timestamp_flag[i] equal to 1 specifies that the $n_frames[i]$ syntax element is followed by $seconds_value[i]$, $minutes_value[i]$ and $hours_value[i]$. **full_timestamp_flag[i]** equal to 0 specifies that the $n_frames[i]$ syntax element is followed by $seconds_flag[i]$.

discontinuity_flag[i] equal to 0 indicates that the difference between the current value of $clockTimestamp[i]$ and the value of $clockTimestamp[i]$ computed from the previous set of clock timestamp syntax elements in output order can be interpreted as the time difference between the times of origin or capture of the associated frames or fields. **discontinuity_flag[i]** equal to 1 indicates that the difference between the current value of $clockTimestamp[i]$ and the value of $clockTimestamp[i]$ computed from the previous set of clock timestamp syntax elements in output order should not be interpreted as the time difference between the times of origin or capture of the associated frames or fields. When **vps_timing_info_present_flag** is equal to 1 and **discontinuity_flag[i]** is equal to 0, the value of $clockTimestamp[i]$ shall be greater than or equal to the value of $clockTimestamp[i]$ for the previous set of clock timestamp syntax elements in output order (when present).

cnt_dropped_flag[i] specifies the skipping of one or more values of $n_frames[i]$ using the counting method specified by **counting_type[i]**.

n_frames[i] specifies the value of $nFrames$ used to compute $clockTimestamp[i]$. When **vps_timing_info_present_flag** is equal to 1, $n_frames[i]$ shall be less than $MaxFPS$, where $MaxFPS$ is specified by

$$MaxFPS = \text{Ceil}(vui_time_scale \div ((1 + units_field_based_flag[i]) * vui_num_units_in_tick)) \quad (D-27)$$

NOTE 4 – $n_frames[i]$ is a frame-based counter. To provide field-specific timing indications when the current picture is a frame, $time_offset_value[i]$ should be used to indicate a distinct $clockTimestamp[i]$ for each field of the frame.

When **counting_type[i]** is equal to 2 and **cnt_dropped_flag[i]** is equal to 1, $n_frames[i]$ shall be equal to 1 and the value of $n_frames[i]$ for the previous set of clock timestamp syntax elements in output order (when present) shall not be equal to 0 unless **discontinuity_flag[i]** is equal to 1.

NOTE 5 – When **counting_type[i]** is equal to 2, the need for increasingly large magnitudes of $tOffset$ in Equation D-26 when using fixed non-integer frame rates (e.g., 12.5 frames per second with vui_time_scale equal to 50 and $vui_num_units_in_tick$ equal to 2 and **units_field_based_flag[i]** equal to 0) can be avoided by occasionally skipping over the value $n_frames[i]$ equal to 0 when counting (e.g., counting $n_frames[i]$ from 0 to 12, then incrementing $seconds_value[i]$ and counting $n_frames[i]$ from 1 to 12, then incrementing $seconds_value[i]$ and counting $n_frames[i]$ from 0 to 12, etc.).

When **vps_timing_info_present_flag** is equal to 1, **counting_type[i]** is equal to 3 and **cnt_dropped_flag[i]** is equal to 1, $n_frames[i]$ shall be equal to 0 and the value of $n_frames[i]$ for the previous set of clock timestamp syntax elements in output order (when present) shall not be equal to $MaxFPS - 1$ unless **discontinuity_flag[i]** is equal to 1.

NOTE 6 – When **counting_type[i]** is equal to 3, the need for increasingly large magnitudes of $tOffset$ in Equation D-26 when using fixed non-integer frame rates (e.g., 12.5 frames per second with vui_time_scale equal to 50 and $vui_num_units_in_tick$ equal to 2 and **units_field_based_flag[i]** equal to 0) can be avoided by occasionally skipping over the value $n_frames[i]$ equal to $MaxFPS - 1$ when counting (e.g., counting $n_frames[i]$ from 0 to 12, then incrementing $seconds_value[i]$ and counting $n_frames[i]$ from 0 to 11, then incrementing $seconds_value[i]$ and counting $n_frames[i]$ from 0 to 12, etc.).

When **counting_type[i]** is equal to 4 and **cnt_dropped_flag[i]** is equal to 1, $n_frames[i]$ shall be equal to 2 and $seconds_value[i]$ shall be equal to zero and $minutes_value[i]$ shall not be an integer multiple of 10 and $n_frames[i]$ for the previous set of clock timestamp syntax elements in output order (when present) shall not be equal to 0 or 1 unless **discontinuity_flag[i]** is equal to 1.

NOTE 7 – When **counting_type[i]** is equal to 4, the need for increasingly large magnitudes of $tOffset$ in Equation D-26 when using fixed non-integer frame rates (e.g., $30000 \div 1001$ frames per second with vui_time_scale equal to 60 000 and $vui_num_units_in_tick$ equal to 1 001 and **units_field_based_flag[i]** equal to 1) can be reduced by occasionally skipping over the values of $n_frames[i]$

equal to 0 and 1 when counting (e.g., counting `n_frames[i]` from 0 to 29, then incrementing `seconds_value[i]` and counting `n_frames[i]` from 0 to 29, etc., until the `seconds_value[i]` is zero and `minutes_value[i]` is not an integer multiple of ten, then counting `n_frames[i]` from 2 to 29, then incrementing `seconds_value[i]` and counting `n_frames[i]` from 0 to 29, etc.). This counting method is well known in the industry and is often referred to as "NTSC drop-frame" counting.

When `vps_timing_info_present_flag` is equal to 1, `counting_type[i]` is equal to 5 or 6 and `cnt_dropped_flag[i]` is equal to 1, `n_frames[i]` shall not be equal to 1 plus the value of `n_frames[i]` for the previous set of clock timestamp syntax elements in output order (when present) modulo `MaxFPS` unless `discontinuity_flag[i]` is equal to 1.

NOTE 8 – When `counting_type[i]` is equal to 5 or 6, the need for increasingly large magnitudes of `tOffset` in Equation D-26 when using fixed non-integer frame rates can be avoided by occasionally skipping over some values of `n_frames[i]` when counting. The specific values of `n_frames[i]` that are skipped are not specified when `counting_type[i]` is equal to 5 or 6.

`seconds_flag[i]` equal to 1 specifies that `seconds_value[i]` and `minutes_flag[i]` are present when `full_timestamp_flag[i]` is equal to 0. `seconds_flag[i]` equal to 0 specifies that `seconds_value[i]` and `minutes_flag[i]` are not present.

`seconds_value[i]` specifies the value of `sS` used to compute `clockTimestamp[i]`. The value of `seconds_value[i]` shall be in the range of 0 to 59, inclusive. When `seconds_value[i]` is not present, its value is inferred to be equal to the value of `seconds_value[i]` for the previous set of clock timestamp syntax elements in decoding order, and it is required that such a previous `seconds_value[i]` shall have been present.

`minutes_flag[i]` equal to 1 specifies that `minutes_value[i]` and `hours_flag[i]` are present when `full_timestamp_flag[i]` is equal to 0 and `seconds_flag[i]` is equal to 1. `minutes_flag[i]` equal to 0 specifies that `minutes_value[i]` and `hours_flag[i]` are not present.

`minutes_value[i]` specifies the value of `mM` used to compute `clockTimestamp[i]`. The value of `minutes_value[i]` shall be in the range of 0 to 59, inclusive. When `minutes_value[i]` is not present, its value is inferred to be equal to the value of `minutes_value[i]` for the previous set of clock timestamp syntax elements in decoding order, and it is required that such a previous `minutes_value[i]` shall have been present.

`hours_flag[i]` equal to 1 specifies that `hours_value[i]` is present when `full_timestamp_flag[i]` is equal to 0 and `seconds_flag[i]` is equal to 1 and `minutes_flag[i]` is equal to 1.

`hours_value[i]` specifies the value of `hH` used to compute `clockTimestamp[i]`. The value of `hours_value[i]` shall be in the range of 0 to 23, inclusive. When `hours_value[i]` is not present, its value is inferred to be equal to the value of `hours_value[i]` for the previous set of clock timestamp syntax elements in decoding order, and it is required that such a previous `hours_value[i]` shall have been present.

`time_offset_length[i]` greater than 0 specifies the length in bits of the `time_offset_value[i]` syntax element. `time_offset_length[i]` equal to 0 specifies that the `time_offset_value[i]` syntax element is not present. When `counting_type[i]` is equal to 0, `time_offset_length[i]` shall be equal to 0.

NOTE 9 – `time_offset_length[i]` should be the same for all values of `i` for all pictures in the CVS.

`time_offset_value[i]` specifies the value of `tOffset` used to compute `clockTimestamp[i]`. The number of bits used to represent `time_offset_value[i]` is equal to `time_offset_length[i]`. When `time_offset_value[i]` is not present, its value is inferred to be equal to 0.

D.3.28 Mastering display colour volume SEI message semantics

This SEI message identifies the colour volume (the colour primaries, white point, and luminance range) of a display considered to be the mastering display for the associated video content – e.g., the colour volume of a display that was used for viewing while authoring the video content. The described mastering display is a three-colour additive display system that has been configured to use the indicated mastering colour volume.

This SEI message does not identify the measurement methodologies and procedures used for determining the indicated values or provide any description of the mastering environment. It also does not provide information on colour transformations that would be appropriate to preserve creative intent on displays with colour volumes different from that of the described mastering display.

The information conveyed in this SEI message is intended to be adequate for purposes corresponding to the use of SMPTE ST 2086 (2018).

When a mastering display colour volume SEI message is present for any picture of a CLVS of a particular layer, a mastering display colour volume SEI message shall be present for the first picture of the CLVS. The mastering display colour volume SEI message persists for the current layer in decoding order from the current picture until the end of the CLVS. All mastering display colour volume SEI messages that apply to the same CLVS shall have the same content.

`display_primaries_x[c]`, when in the range of 5 to 37 000, inclusive, specifies the normalized `x` chromaticity coordinate of the colour primary component `c` of the mastering display, according to the CIE 1931 definition of `x` as specified in ISO

11664-1 (see also ISO 11664-3 and CIE 15), in increments of 0.00002. When `display primaries_x[c]` is not in the range of 5 to 37 000, inclusive, the normalized x chromaticity coordinate of the colour primary component c of the mastering display is unknown or unspecified or specified by other means not specified in this Specification.

display_primaries_y[c], when in the range of 5 to 42 000, inclusive, specifies the normalized y chromaticity coordinate of the colour primary component c of the mastering display, according to the CIE 1931 definition of y as specified in ISO 11664-1 (see also ISO 11664-3 and CIE 15), in increments of 0.00002. When `display_primaries_y[c]` is not in the range of 5 to 42 000, inclusive, the normalized y chromaticity coordinate of the colour primary component c of the mastering display is unknown or unspecified or specified by other means not specified in this Specification.

For describing mastering displays that use red, green, and blue colour primaries, it is suggested that index value c equal to 0 should correspond to the green primary, c equal to 1 should correspond to the blue primary, and c equal to 2 should correspond to the red colour primary (see also Annex E and Table E.3).

white_point_x, when in the range of 5 to 37 000, inclusive, specifies the normalized x chromaticity coordinate of the white point of the mastering display, according to the CIE 1931 definition of x as specified in ISO 11664-1 (see also ISO 11664-3 and CIE 15), in normalized increments of 0.00002. When `white_point_x` is not in the range of 5 to 37 000, inclusive, the normalized x chromaticity coordinate of the white point of the mastering display is indicated to be unknown or unspecified or specified by other means not specified in this Specification.

white_point_y, when in the range of 5 to 42 000, inclusive, specifies the normalized y chromaticity coordinate of the white point of the mastering display, according to the CIE 1931 definition of y as specified in ISO 11664-1 (see also ISO 11664-3 and CIE 15), in normalized increments of 0.00002. When `white_point_y` is not in the range of 5 to 42 000, inclusive, the normalized y chromaticity coordinate of the white point of the mastering display is indicated to be unknown or unspecified or specified by other means not specified in this Specification.

NOTE 1 – SMPTE ST 2086 (2018) specifies that the normalized x and y chromaticity coordinate values for the mastering display colour primaries and white point are to be represented with four decimal places. This would correspond with using values of the syntax elements `display_primaries_x[c]`, `display_primaries_y[c]`, `white_point_x`, and `white_point_y`, as defined in this Specification, that are multiples of 5.

NOTE 2 – An example of the use of values outside the range for which semantics are specified in this Specification is that ANSI/CTA 861-G (2016) uses normalized (x, y) chromaticity coordinate values of (0,0) for the white point to indicate that the white point chromaticity is unknown.

max_display_mastering_luminance, when in the range of 50 000 to 100 000 000, specifies the nominal maximum display luminance of the mastering display in units of 0.0001 candelas per square metre. When `max_display_mastering_luminance` is not in the range of 50 000 to 100 000 000, the nominal maximum display luminance of the mastering display is indicated to be unknown or unspecified or specified by other means not specified in this Specification.

NOTE 3 – SMPTE ST 2086 (2018) specifies that the nominal maximum display luminance of the mastering display is to be specified as a multiple of 1 candela per square meter. This would correspond with using values of the syntax element `max_display_mastering_luminance`, as defined in this Specification, that are a multiple of 10 000.

NOTE 4 – An example of the use of values outside the range for which semantics are specified in this Specification is that ANSI/CTA 861-G (2016) uses the value 0 for the nominal maximum display luminance of the mastering display to indicate that the nominal maximum display luminance of the mastering display is unknown.

min_display_mastering_luminance, when in the range of 1 to 50 000, specifies the nominal minimum display luminance of the mastering display in units of 0.0001 candelas per square metre. When `min_display_mastering_luminance` is not in the range of 1 to 50 000, the nominal maximum display luminance of the mastering display is unknown or unspecified or specified by other means not specified in this Specification. When `max_display_mastering_luminance` is equal to 50 000, `min_display_mastering_luminance` shall not be equal to 50 000.

NOTE 5 – SMPTE ST 2086 (2018) specifies that the nominal minimum display luminance of the mastering display is to be specified as a multiple of 0.0001 candelas per square metre, which corresponds to the semantics specified in this Specification.

NOTE 6 – An example of the use of values outside the range for which semantics are specified in this Specification is that ANSI/CTA 861-G (2016) uses the value 0 for the nominal minimum display luminance of the mastering display to indicate that the nominal minimum display luminance of the mastering display is unknown.

NOTE 7 – Another example of the potential use of values outside the range for which semantics are specified in this Specification is that SMPTE ST 2086 (2018) indicates that values outside the specified range could be used to indicate that the black level and contrast of the mastering display have been adjusted using picture line-up generation equipment (PLUGE).

At the minimum luminance, the mastering display is considered to have the same nominal chromaticity as the white point.

D.3.29 Segmented rectangular frame packing arrangement SEI message semantics

This SEI message informs the decoder that the output cropped decoded picture contains samples of multiple distinct spatially packed constituent frames that are packed into one frame using a rectangular region frame packing arrangement. This information can be used by the decoder to appropriately rearrange the samples and process the samples of the constituent frames appropriately for display or other purposes (which are outside the scope of this Specification).

Each colour component plane of the output cropped decoded pictures contains a rectangular region frame packing arrangement of corresponding planes of two constituent frames as illustrated in Figure D.10.

NOTE 1 – Figure D.10 provides an illustration of the rearrangement process for the rectangular region frame packing arrangement.

This SEI message may be associated with pictures that are either frames (when `field_seq_flag` is equal to 0) or fields (when `field_seq_flag` is equal to 1). The rectangular region frame packing arrangement of the samples is specified in terms of the sampling structure of a frame in order to define a frame packing arrangement structure that is invariant with respect to whether a picture is a single field of such a packed frame or is a complete packed frame.

When `general_non_packed_constraint_flag` is equal to 1 in the active SPS for the current layer, there shall be no segmented rectangular frame packing arrangement SEI messages applicable for any picture of the CLVS of the current layer.

When a frame packing arrangement SEI message is applicable for any picture of the CLVS of the current layer, there shall be no segmented rectangular frame packing arrangement SEI messages applicable for any picture of the CLVS of the current layer.

`segmented_rect_frame_packing_arrangement_cancel_flag` equal to 1 indicates that the SEI message cancels the persistence of any previous segmented rectangular frame packing arrangement SEI message in output order. `segmented_rect_frame_packing_arrangement_cancel_flag` equal to 0 indicates that rectangular region frame packing arrangement information follows.

`segmented_rect_content_interpretation_type` indicates the intended interpretation of the constituent frames as specified in Table D.12. Values of `segmented_rect_content_interpretation_type` that do not appear in Table D.12 are reserved for future specification by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore rectangular region frame packing arrangement SEI messages that contain reserved values of `segmented_rect_content_interpretation_type`.

For the specified frame packing arrangement scheme, there are two constituent frames that are referred to as frame 0 and frame 1.

Table D.12 – Definition of `segmented_rect_content_interpretation_type`

Value	Interpretation
0	Unspecified relationship between the frame packed constituent frames
1	Indicates that the two constituent frames form the left and right views of a stereo view scene, with frame 0 being associated with the left view and frame 1 being associated with the right view
2	Indicates that the two constituent frames form the right and left views of a stereo view scene, with frame 0 being associated with the right view and frame 1 being associated with the left view

NOTE 2 – The value 2 for `segmented_rect_content_interpretation_type` is not expected to be prevalent in industry use of this SEI message. However, the value was specified herein for purposes of completeness.

`segmented_rect_frame_packing_arrangement_persistence_flag` specifies the persistence of the segmented rectangular frame packing arrangement SEI message for the current layer.

`segmented_rect_frame_packing_arrangement_persistence_flag` equal to 0 specifies that the rectangular region frame packing arrangement SEI message applies to the current decoded frame only.

Let `picA` be the current picture. `segmented_rect_frame_packing_arrangement_persistence_flag` equal to 1 specifies that the segmented rectangular frame packing arrangement SEI message persists for the current layer in output order until any of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A frame `picB` in the current layer in an access unit containing a segmented rectangular frame packing arrangement SEI message applicable to the current layer is output for which `PicOrderCnt(picB)` is greater than `PicOrderCnt(picA)`, where `PicOrderCnt(picB)` and `PicOrderCnt(picA)` are the `PicOrderCntVal` values of `picB` and `picA`, respectively, immediately after the invocation of the decoding process for picture order count for `picB`.

NOTE 3 – The default display window parameters in the VUI parameters of the SPS should be used by an encoder to indicate to a decoder that does not interpret the rectangular region frame packing arrangement SEI message that the default display window is an area within only one of the two constituent frames.

Let `croppedWidth` and `croppedHeight` be the width and height, respectively, of the cropped frame output from the decoder in units of luma samples, derived as follows:

$$\text{croppedWidth} = \text{pic_width_in_luma_samples} - \text{SubWidthC} * (\text{conf_win_right_offset} + \text{conf_win_left_offset}) \quad (\text{D-28})$$

$$\text{croppedHeight} = \text{pic_height_in_luma_samples} - \text{SubHeightC} * (\text{conf_win_bottom_offset} + \text{conf_win_top_offset}) \quad (\text{D-29})$$

It is a requirement of bitstream conformance for the rectangular region frame packing arrangement that `croppedWidth` and `croppedHeight` shall be integer multiples of 3.

Let `oneThirdWidth` and `oneThirdHeight` be derived as follows:

$$\text{oneThirdWidth} = \text{croppedWidth} / 3 \quad (\text{D-30})$$

$$\text{oneThirdHeight} = \text{croppedHeight} / 3 \quad (\text{D-31})$$

The rectangular region frame packing arrangement is composed of five rectangular regions identified as R0, R1, R2, R3 and R4 as illustrated in Figure D.10.

The width and height of the region R0 are specified in units of frame luma samples as follows:

$$\text{r0}_W = 2 * \text{oneThirdWidth} \quad (\text{D-32})$$

$$\text{r0}_H = 2 * \text{oneThirdHeight} \quad (\text{D-33})$$

The width and height of the region R1 are specified in units of frame luma samples as follows:

$$\text{r1}_W = \text{oneThirdWidth} \quad (\text{D-34})$$

$$\text{r1}_H = 2 * \text{oneThirdHeight} \quad (\text{D-35})$$

The width and height of the region R2 are specified in units of frame luma samples as follows:

$$\text{r2}_W = \text{oneThirdWidth} \quad (\text{D-36})$$

$$\text{r2}_H = \text{oneThirdHeight} \quad (\text{D-37})$$

The width and height of the region R3 are specified in units of frame luma samples as follows:

$$\text{r3}_W = \text{oneThirdWidth} \quad (\text{D-38})$$

$$\text{r3}_H = \text{oneThirdHeight} \quad (\text{D-39})$$

The width and height of the region R4 are specified in units of frame luma samples as follows:

$$\text{r4}_W = \text{oneThirdWidth} \quad (\text{D-40})$$

$$\text{r4}_H = \text{oneThirdHeight} \quad (\text{D-41})$$

Constituent frame 0 is obtained by cropping from the decoded frames the region R0 and constituent frame 1 is obtained by stacking vertically the regions R2 and R3 and placing the resulting rectangle to the right of the region R1. The region R4 is not part of either constituent frame and is discarded.

Figure D.10 – Rearrangement of a segmented rectangular frame packing arrangement

D.3.30 Temporal motion-constrained tile sets SEI message semantics

The temporal motion-constrained tile sets SEI message indicates that the following constraints apply:

- No sample values outside each identified tile set or outside the picture are referenced for inter prediction.
- For PUs located directly left of the right tile boundary of each identified tile set except the last one at the bottom right, the following applies when $\text{CuPredMode}[xPb][yPb]$ is equal to MODE_INTER , where (xPb, yPb) specifies the top-left sample of the corresponding luma prediction block relative to the top-left sample of the current picture:
 - With the number of spatial merging candidates $\text{numSpatialMergeCand}$ derived as follows:

$$\begin{aligned} \text{numSpatialMergeCand} = & \text{availableFlagA}_0 + \text{availableFlagA}_1 + \\ & \text{availableFlagB}_0 + \text{availableFlagB}_1 + \text{availableFlagB}_2 \end{aligned} \quad (\text{D-42})$$

where availableFlagA_0 , availableFlagA_1 , availableFlagB_0 , availableFlagB_1 , and availableFlagB_2 are the output of the derivation process for spatial merging candidates specified in clause 8.5.3.2.3, the following applies:

- If $\text{numSpatialMergeCand}$ is equal to 0, $\text{merge_flag}[xPb][yPb]$ is equal to 0.
- Otherwise ($\text{numSpatialMergeCand}$ is greater than 0), $\text{merge_idx}[xPb][yPb]$ is in the range of 0 to $\text{numSpatialMergeCand} - 1$, inclusive.
- With the number of spatial motion vector predictor candidates numSpatialMvpCand derived as follows:

$$\begin{aligned} \text{if}(\text{availableFlagLXA}) \\ \text{numSpatialMvpCand} = & \text{availableFlagLXA} + ((\text{mvLXA} \neq \text{mvLXB}) ? \text{availableFlagLXB} : 0) \\ \text{else} \\ \text{numSpatialMvpCand} = & \text{availableFlagLXB} \end{aligned} \quad (\text{D-43})$$

where availableFlagLXA , availableFlagLXB , mvLXA , and mvLXB are the output of the derivation process for motion vector predictor candidates from neighbouring prediction unit partitions specified in clause 8.5.3.2.7, the following applies:

- If numSpatialMvpCand is equal to 0, $\text{mvp_l0_flag}[xPb][yPb]$ and $\text{mvp_l1_flag}[xPb][yPb]$ are equal to 1.
- Otherwise (numSpatialMvpCand is greater than 0), $\text{mvp_l0_flag}[xPb][yPb]$ and $\text{mvp_l1_flag}[xPb][yPb]$ are in the range of 0 to $\text{numSpatialMvpCand} - 1$, inclusive.

NOTE 1 – The first constraint restricts motion vector values to only those that refer either to full-sample locations inside each identified tile set or to fractional-sample locations that require only full-sample locations inside each identified tile set for

interpolation. The second constraint prohibits the usage of motion vector candidates for temporal motion vector prediction that are derived from blocks outside each identified tile set.

Let a set of pictures associatedPicSet be the pictures with nuh_layer_id equal to targetLayerId from the access unit containing the SEI message, inclusive, up to but not including the first of any of the following in decoding order:

- The next access unit, in decoding order, that contains a temporal motion-constrained tile sets SEI message applicable to targetLayerId.
- The next IRAP picture with NoRaslOutputFlag equal to 1, in decoding order, with nuh_layer_id equal to targetLayerId.
- The next IRAP access unit, in decoding order, with NoClasOutputFlag equal to 1.

The scope of the temporal motion-constrained tile sets SEI message is the set of pictures associatedPicSet.

When a temporal motion-constrained tile sets SEI message is present for any picture in associatedPicSet, a temporal motion-constrained tile sets SEI message applicable to targetLayerId shall be present for the first picture of associatedPicSet in decoding order and may also be present for other pictures of associatedPicSet.

When a temporal motion-constrained tile sets SEI message applicable to targetLayerId is present for a picture in associatedPicSet and tiles_enabled_flag is equal to 0 for the PPS that is active for the picture, the picture contains only one tile, which forms the only MCTS, and the values of mc_all_tiles_exact_sample_value_match_flag and each_tile_one_tile_set_flag shall both be equal to 1.

The temporal motion-constrained tile sets SEI message applicable to targetLayerId shall not be present for any picture in associatedPicSet unless every PPS that is active for any picture in associatedPicSet has the same values of the syntax elements num_tile_columns_minus1, num_tile_rows_minus1, uniform_spacing_flag, column_width_minus1[i] and row_height_minus1[i].

NOTE 2 – This constraint is similar to the constraint associated with tiles_fixed_structure_flag equal to 1 and it may be desirable for tiles_fixed_structure_flag to be equal to 1 when the temporal motion-constrained tile sets SEI message is present (although this is not required).

NOTE 3 – When loop filtering is applied across tile boundaries, inter prediction of any samples within a temporal motion-constrained tile set that refers to samples within four samples from a temporal motion-constrained tile set boundary that is not also a picture boundary may result in propagation of mismatch error. An encoder can avoid such potential error propagation by avoiding the use of motion vectors that cause such references.

When more than one temporal motion-constrained tile sets SEI message applicable to targetLayerId is present for the pictures of associatedPicSet, they shall contain identical content.

When a temporal motion-constrained tile sets SEI message is present, a slice segment that contains one or more tiles in any particular temporal motion-constrained tile set shall not be a dependent slice segment of an independent slice segment that contains one or more tiles that do not belong to that temporal motion-constrained tile set.

For purposes of referencing a particular temporal motion-constrained tile set that is identified in a temporal motion-constrained tile sets SEI message (e.g., for use with a motion-constrained tile sets extraction information sets SEI message or a motion-constrained tile sets extraction information nesting SEI message), an MCTS index is defined as follows:

- If the value of each_tile_one_tile_set_flag of the temporal motion-constrained tile sets SEI message is equal to 0, the MCTS index is the value of the variable i within the loop of the num_sets_in_message_minus1 + 1 sets of MCTS information specified by the temporal MCTS SEI message.
- Otherwise, the MCTS index of each MCTS is the tile position of the tile in tile raster scan order.

mc_all_tiles_exact_sample_value_match_flag equal to 0 indicates that when the CTUs that do not belong to any tile in the motion-constrained tile sets are not decoded and the boundaries of the tiles in the motion-constrained tile sets are treated as picture boundaries for purposes of the decoding process, the decoded value of each sample in the tiles in the motion-constrained tile sets may not be exactly the same as the decoded value of the same sample when all the CTUs of the picture are decoded. mc_all_tiles_exact_sample_value_match_flag equal to 1 indicates that when the CTUs that do not belong to any tile in the motion-constrained tile sets are not decoded and the boundaries of the tiles in the motion-constrained tile sets are treated as picture boundaries for purposes of the decoding process, the decoded value of each sample in the tiles in the motion-constrained tile sets is exactly the same as the decoded value of the sample that would be obtained when all the CTUs of all pictures in associatedPicSet are decoded.

each_tile_one_tile_set_flag equal to 1 indicates that each and every tile in the picture is included in a separate temporal motion-constrained tile set. each_tile_one_tile_set_flag equal to 0 indicates that such constraint may not be applied.

limited_tile_set_display_flag equal to 1 specifies that the display_tile_set_flag[i] syntax element is present and indicates that the tiles not included within any tile set with display_tile_set_flag[i] equal to 1 are not intended for display. limited_tile_set_display_flag equal to 0 specifies that the display_tile_set_flag[i] syntax element is not present.

num_sets_in_message_minus1 plus 1 specifies the number of temporal motion-constrained tile sets identified in the SEI message. The value of **num_sets_in_message_minus1** shall be in the range of 0 to 255, inclusive.

mcts_id[i] contains an identifying number that may be used to identify the purpose of the *i*-th identified tile set (for example, to identify an area to be extracted from associatedPicSet for a particular purpose). The value of **mcts_id[i]** shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of **mcts_id[i]** from 0 to 255, inclusive, and from 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of **mcts_id[i]** from 256 to 511, inclusive, and from 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC and bitstreams shall not contain such values. Decoders encountering a value of **mcts_id[i]** in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

display_tile_set_flag[i] equal to 1 indicates that the *i*-th tile set is intended for display. **display_tile_set_flag[i]** equal to 0 indicates that the *i*-th tile set is not intended for display. When not present, the value of **display_tile_set_flag[i]** is inferred to be equal to 1.

num_tile_rects_in_set_minus1[i] plus 1 specifies the number of rectangular regions of tiles in the *i*-th identified temporal motion-constrained tile set. The value of **num_tile_rects_in_set_minus1[i]** shall be in the range of 0 to $(\text{num_tile_columns_minus1} + 1) * (\text{num_tile_rows_minus1} + 1) - 1$, inclusive.

top_left_tile_idx[i][j] and **bottom_right_tile_idx[i][j]** identify the tile position of the top-left tile and the tile position of the bottom-right tile in a rectangular region of the *i*-th identified temporal motion-constrained tile set, respectively, in tile raster scan order.

The value of **top_left_tile_idx[i][j]** and **bottom_right_tile_idx[i][j]** shall be in the range of 0 to $(\text{num_tile_columns_minus1} + 1) * (\text{num_tile_rows_minus1} + 1) - 1$, inclusive.

mc_exact_sample_value_match_flag[i] equal to 0 indicates that when the CTUs that are outside of the *i*-th identified temporal motion-constrained tile set are not decoded and the boundaries of the temporal motion-constrained tile set are treated as picture boundaries for purposes of the decoding process, the value of each sample in the identified tile set may not be exactly the same as the value of the same sample when all the CTUs of the picture are decoded. **mc_exact_sample_value_match_flag[i]** equal to 1 indicates that when the CTUs that do not belong to the temporal motion-constrained tile set are not decoded and the boundaries of the temporal motion-constrained tile set are treated as picture boundaries for purposes of the decoding process, the value of each sample in the temporal motion-constrained tile set would be exactly the same as the value of the sample that would be obtained when all the CTUs of all pictures in associatedPicSet are decoded.

NOTE 4 – It should be feasible to use **mc_exact_sample_value_match_flag[i]** equal to 1 when using certain combinations of **loop_filter_across_tiles_enabled_flag**, **pps_loop_filter_across_slices_enabled_flag**, **pps_deblocking_filter_disabled_flag**, **slice_loop_filter_across_slices_enabled_flag**, **slice_deblocking_filter_disabled_flag**, **sample_adaptive_offset_enabled_flag**, **slice_sao_luma_flag** and **slice_sao_chroma_flag**.

mcts_tier_level_idc_present_flag[i] equal to 1 specifies that the **mcts_tier_flag[i]** and **mcts_level_idc[i]** syntax elements are present. **mcts_tier_level_idc_present_flag[i]** equal to 0 specifies that the **mcts_tier_flag[i]** and **mcts_level_idc[i]** syntax elements are not present. When **mcts_tier_level_idc_present_flag[i]** is equal to 1, **num_tile_rects_in_set_minus1[i]** shall be equal to 0 and a slice segment containing one or more CTUs within the *i*-th motion-constrained tile set shall not include any CTU outside the *i*-th motion-constrained tile set. When not present, **mcts_tier_level_idc_present_flag[i]** is inferred to be equal to 0.

mcts_tier_flag[i] specifies the tier context for the interpretation of **mcts_level_idc[i]** corresponding to the *i*-th motion-constrained tile set. **mcts_tier_flag[i]** equal to 0 indicates conformance to the Main tier, and **mcts_tier_flag[i]** equal to 1 indicates conformance to the High tier, according to the tier constraints specified in Table A.8. **mcts_tier_flag[i]** shall be equal to 0 when **mcts_level_idc[i]** is less than 120. When not present, the value of **mcts_tier_flag[i]** is inferred to be equal to **general_tier_flag**.

mcts_level_idc[i] indicates a level to which the *i*-th tile set region, corresponding to the *i*-th motion-constrained tile set, conforms. The value of **mcts_level_idc[i]** shall be less than or equal to the value of **general_level_idc** in the active SPS RBSP. When not present, the value of **mcts_level_idc[i]** is inferred to be equal to **general_level_idc**.

mcts_max_tier_level_idc_present_flag equal to 1 specifies that the **mcts_max_tier_flag** and **mcts_max_level_idc** syntax elements are present. **mcts_max_tier_level_idc_present_flag** equal to 0 specifies that the **mcts_max_tier_flag** and **mcts_max_level_idc** syntax elements are not present. When **mcts_max_tier_level_idc_present_flag** is equal to 1, a slice segment containing one or more CTUs within a tile shall not include any CTU outside the tile. When not present, **mcts_max_tier_level_idc_present_flag** is inferred to be equal to 0.

mcts_max_tier_flag specifies the tier context for the interpretation of **mcts_max_level_idc** to which all motion-constrained tile sets conform. **mcts_max_tier_flag** equal to 0 indicates conformance to the Main tier, and **mcts_max_tier_flag** equal to 1 indicates conformance to the High tier, according to the tier constraints specified in Table A.8. **mcts_max_tier_flag** shall be equal to 0 when **mcts_max_level_idc** is less than 120. When not present, the value of **mcts_max_tier_flag** is inferred to be equal to **general_tier_flag**.

mcts_max_level_idc indicates a level to which all motion-constrained tile sets conform. The value of **mcts_max_level_idc** shall be less than or equal to the value of **general_level_idc** in the active SPS RBSP. When not present, the value of **mcts_max_level_idc** is inferred to be equal to **general_level_idc**.

The following describes the tier and level restrictions on the bitstreams of each motion-constrained tile set:

- If **mcts_tier_level_idc_present_flag[i]** and **mcts_max_tier_level_idc_present_flag** are both equal to 0, the **mctsLevelIdc[i]** of all motion-constrained tile sets are inferred to be equal to **general_level_idc** and the **mctsTierFlag[i]** of all motion-constrained tile sets are inferred to be equal to **general_tier_flag** and the specifications of Annex A apply to all motion-constrained tile sets.
- Otherwise (**mcts_tier_level_idc_present_flag[i]** or **mcts_max_tier_level_idc_present_flag** is equal to 1), the following applies:
 - The variables **mctsLevelIdc[i]**, **mctsTierFlag[i]**, **mctsWidthInSamplesY[i]**, **mctsHeightInSamplesY[i]**, **NumTileColumnsInMCTS[i]** and **NumTileRowsInMCTS[i]** are derived as follows:
 - If **each_tile_one_tile_set_flag** is equal to 0, for each tile set with index *i* in the range of 0 to **num_sets_in_message_minus1**, inclusive, the following applies:
 - **mctsLevelIdc[i]** is set equal to **mcts_level_idc[i]**.
 - **mctsTierFlag[i]** is set equal to **mcts_tier_flag[i]**.
 - **mctsWidthInSamplesY[i]** is set equal to the sum of **ColumnWidthInLumaSamples[k]**, for all *k* in the range of (**top_left_tile_idx[i][0] % (num_tile_rows_minus1 + 1)**) to (**bottom_right_tile_idx[i][0] % (num_tile_rows_minus1 + 1)**), inclusive.
 - **mctsHeightInSamplesY[i]** is set equal to the sum of **RowHeightInLumaSamples[k]**, for all *k* in the range of (**top_left_tile_idx[i][0] / (num_tile_rows_minus1 + 1)**) to (**bottom_right_tile_idx[i][0] / (num_tile_rows_minus1 + 1)**), inclusive.
 - **NumTileColumnsInMCTS[i]** is set equal to $(\text{bottom_right_tile_idx}[i][0] \% (\text{num_tile_rows_minus1} + 1)) - (\text{top_left_tile_idx}[i][0] \% (\text{num_tile_rows_minus1} + 1)) + 1$.
 - **NumTileRowsInMCTS[i]** is set equal to $(\text{bottom_right_tile_idx}[i][0] / (\text{num_tile_rows_minus1} + 1)) - (\text{top_left_tile_idx}[i][0] / (\text{num_tile_rows_minus1} + 1)) + 1$.
 - Otherwise (**each_tile_one_tile_set_flag** is equal to 1), for each tile with **TileId i**, with *i* in the range of 0 to $(\text{num_tile_columns_minus1} + 1) * (\text{num_tile_rows_minus1} + 1) - 1$, inclusive, the following applies:
 - **mctsLevelIdc[i]** is set equal to **mcts_max_level_idc**.
 - **mctsTierFlag[i]** is set equal to **mcts_max_tier_flag**.
 - **mctsWidthInSamplesY[i]** is set equal to **ColumnWidthInLumaSamples[i % (num_tile_rows_minus1 + 1)]**.
 - **mctsHeightInSamplesY[i]** is set equal to **RowHeightInLumaSamples[i / (num_tile_rows_minus1 + 1)]**.
 - **NumTileColumnsInMCTS[i]** is set equal to 1.
 - **NumTileRowsInMCTS[i]** is set equal to 1.
 - The variables **mctsSizeInSamplesY[i]** and **NumSliceSegmentsInMCTS[i]** are derived as follows:
 - **mctsSizeInSamplesY[i]** is set equal to **mctsWidthInSamplesY[i] * mctsHeightInSamplesY[i]**.
 - **NumSliceSegmentsInMCTS[i]** is set equal to the number of slice segments in the *i*-th motion-constrained tile set.
 - The variables **mctsMaxLumaPs[i]**, **mctsMaxCPB[i]**, **mctsMaxSliceSegments[i]**, **mctsMaxTileRows[i]**, **mctsMaxTileCols[i]**, **mctsMaxBR[i]** and **mctsMinCr[i]** are set equal to **MaxLumaPs**, **MaxCPB**, **MaxSliceSegmentsPerPicture**, **MaxTileRows**, **MaxTileCols** and **MaxBR**, respectively, specified in Table A.8 for the level indicated by **mctsLevelIdc[i]** with the tier indicated by **mctsTierFlag[i]**.
 - The variable **mctsMinCr[i]** is set equal to **MinCr** specified in Table A.9 for the level indicated by **mctsLevelIdc[i]** with the tier indicated by **mctsTierFlag[i]**.
 - **mctsLevelIdc[i]** and **mctsTierFlag[i]** indicate the level and tier to which the *i*-th motion-constrained tile set conforms, as specified in Annex A with the following modifications and additions:
 - The variable **PicSizeInSamplesY** is replaced with the variable **mctsSizeInSamplesY[i]**.
 - The value of **num_tile_columns_minus1** is replaced with the variable **NumTileColumnsInMCTS[i] - 1**.
 - The value of **num_tile_rows_minus1** is replaced with the variable **NumTileRowsInMCTS[i] - 1**.

- The number of slice segments for the i-th motion-constrained tile set is set to NumSliceSegmentsInMCTS[i].
- The variable MaxTileCols, MaxTileRows, MaxSliceSegmentsPerPicture, MaxLumaPs, MaxBR and MinCr are replaced with the variables mctsMaxTileCols[i], mctsMaxTileRows[i], mctsMaxSliceSegments[i], mctsMaxLumaPs[i], mctsMaxBR[i] and mctsMinCr[i], respectively.
- The nominal removal time of motion-constrained tile set from the CPB shall be the same as removal time of corresponding access unit.
- The difference between consecutive output times of motion-constrained tile sets from the DPB shall be same as difference between the output times of corresponding access unit.
- The value of NumBytesInNalUnit is replaced with the sum of the sizes of all NAL units belonging to the i-th motion-constrained tile set in bytes.

D.3.31 Chroma resampling filter hint SEI message semantics

The chroma resampling filter hint SEI message signals one downsampling process and one upsampling process for the chroma components of decoded pictures. When the sampling processes signalled in the chroma resampling filter hint SEI message are used, for any number of upsampling and downsampling iterations performed on the decoded pictures, the degradation of the colour components is expected to be minimized.

The chroma resampling filter hint SEI message shall not be present in a CLVS that has chroma_format_idc equal to 0.

It is a requirement of bitstream conformance that when a chroma resampling filter hint SEI message is present in a CLVS, chroma_sample_loc_type_top_field shall be equal to chroma_sample_loc_type_bottom_field in the same CLVS.

All chroma resampling filter hint SEI messages that apply to the same CLVS shall have the same content.

ver_chroma_filter_idc identifies the vertical components of the downsampling and upsampling sets of filters as specified in Table D.13. Based on the value of ver_chroma_filter_idc, the values of verFilterCoeff[][] are derived from Table D.18. The value of ver_chroma_filter_idc shall be in the range of 0 to 2, inclusive. Values of ver_chroma_filter_idc greater than 2 are reserved for future use by ITU-T | ISO/IEC.

When ver_chroma_filter_idc is equal to 0, the chroma resampling filter in the vertical direction is unspecified.

When chroma_format_idc is equal to 1, ver_chroma_filter_idc shall be equal to 1 or 2.

Table D.13 – ver_chroma_filter_idc values

Value	Description
0	Unspecified
1	Filters signalled by ver_filter_coeff[][]
2	Filters as described in SMPTE RP 2050-1 (2012)
>2	Reserved

hor_chroma_filter_idc identifies the horizontal components of the downsampling and upsampling sets of filters as specified in Table D.14. Based on the value of hor_chroma_filter_idc, the values of horFilterCoeff[][] are derived from Table D.19. The value of hor_chroma_filter_idc shall be in the range of 0 to 2, inclusive. Values of hor_chroma_filter_idc greater than 2 are reserved for future use by ITU-T | ISO/IEC.

When hor_chroma_filter_idc is equal to 0, the chroma resampling filter in the horizontal direction is unspecified.

When chroma_format_idc is equal to 3, hor_chroma_filter_idc shall be equal to 1 or 2.

When chroma_format_idc is equal to 2 and ver_chroma_filter_idc is equal to 2, hor_chroma_filter_idc shall be equal to 0.

It is a requirement of bitstream conformance that ver_chroma_filter_idc and hor_chroma_filter_idc shall not be both equal to 0.

Table D.14 – hor_chroma_filter_idc values

Value	Description
0	Unspecified
1	Filters signalled by hor_filter_coeff[][]
2	Filters as described in the 5/3 filter description of Rec. ITU-T T.800 ISO/IEC 15444-1
>2	Reserved

ver_filtering_field_processing_flag indicates whether the vertical operations of the downsampling and the upsampling sets of filters should be applied on a field-basis or a frame-basis. When **field_seq_flag** is equal to 1 and **pic_struct** is not within the range of 9 to 12 inclusive, **ver_filtering_field_processing_flag** shall be equal to 1.

Based on the values of **ver_filtering_field_processing_flag** and **field_seq_flag**, the following applies:

- If **ver_filtering_field_processing_flag** is equal to 1:
 - If **field_seq_flag** is equal to 1, each output field should be filtered independently.
 - Otherwise (**field_seq_flag** is equal to 0), for each decoded frame the filtering process should be applied to chroma samples belonging to the top field and to chroma samples belonging to the bottom field separately.
- Otherwise (**ver_filtering_field_processing_flag** is equal to 0):
 - If **field_seq_flag** is equal to 1, the filtering process should be performed on a frame basis. The input of the filtering process should be frames resulting from the interleaving of fields in accordance with the information conveyed by the **pic_struct** values.
 - Otherwise (**field_seq_flag** is equal to 0), the filtering process should be performed on a frame basis.

The variable **chromaSampleLocType** is derived as follows:

- If **chroma_format_idc** is equal to 1, **chromaSampleLocType** is set equal to **chroma_sample_loc_type_top_field**.
- Otherwise (**chroma_format_idc** is not equal to 1), **chromaSampleLocType** is set equal to 0.

When **chromaSampleLocType** is greater than 1, **ver_chroma_filter_idc** shall not be equal to 2.

When **chromaSampleLocType** is equal to 1, 3 or 5, **hor_chroma_filter_idc** shall not be equal to 2.

target_format_idc indicates the output sampling format of the chroma components (i.e., the position of chroma samples relative to that of the luma samples) after filtering, as specified in Table D.15. The value of **target_format_idc** shall be in the range of 1 to 3, inclusive. The value of **target_format_idc** shall not be equal to the value of **chroma_format_idc**.

When not present, the value of **target_format_idc** is inferred as follows:

- If **chroma_format_idc** is equal to 1 and **ver_chroma_filter_idc** is equal to 2, the following applies:
 - If **hor_chroma_filter_idc** is not equal to 2, the value of **target_format_idc** is inferred to be equal to 2.
 - Otherwise (**hor_chroma_filter_idc** is equal to 2), the value of **target_format_idc** is inferred to be equal to 3.
- Otherwise, if **chroma_format_idc** is equal to 2, the following applies:
 - If **ver_chroma_filter_idc** is equal to 2, the value of **target_format_idc** is inferred to be equal to 1.
 - Otherwise (**ver_chroma_filter_idc** is not equal to 2), the value of **target_format_idc** is inferred to be equal to 3.
- Otherwise, if **chroma_format_idc** is equal to 3, the following applies:
 - If **ver_chroma_filter_idc** is equal to 2, the value of **target_format_idc** is inferred to be equal to 1.
 - Otherwise (**ver_chroma_filter_idc** is not equal to 2), the value of **target_format_idc** is inferred to be equal to 2.

When **chroma_format_idc** is greater than 1 and **target_format_idc** is greater than 1, **ver_chroma_filter_idc** shall be equal to 0.

When **chroma_format_idc** is less than 3 and **target_format_idc** is less than 3, **hor_chroma_filter_idc** shall be equal to 0.

Table D.15 – Chroma sampling format indicated by target_format_idc

target_format_idc	Chroma sampling format
1	4:2:0
2	4:2:2
3	4:4:4

NOTE 1 – The logic associating sampling formats to numeric values of `target_format_idc` here is the same as the one used to associate sampling formats to numeric values of `chroma_format_idc`, as described in clause 6.2.

The variable `upsamplingFlag` is derived as follows:

- If `chroma_format_idc` is greater than `target_format_idc`, `upsamplingFlag` is set equal to 0.
- Otherwise (`chroma_format_idc` is less than `target_format_idc`), `upsamplingFlag` is set equal to 1.

num_vertical_filters specifies the number of filters signalled for chroma downsampling and upsampling in the vertical direction. When `ver_chroma_filter_idc` is equal to 1, depending on the values of `chromaSampleLocType` and `ver_filtering_field_processing_flag`, the value of `num_vertical_filters` shall be equal to the values specified in Table D.16.

Table D.16 – Constraints on the value of num_vertical_filters

Conditions		Mandatory value of num_vertical_filters
chromaSampleLocType	ver_filtering_field_processing_flag	
0, 1	0	2
	1	3
2, 3	0	3
	1	5
4, 5	0	3
	1	5

ver_tap_length_minus1[i] plus 1 specifies the length of the *i*-th filter in the vertical direction. The value of `ver_tap_length_minus1[i]` shall be in the range of 0 to 31, inclusive.

ver_filter_coeff[i][j] specifies the value of the *j*-th coefficient of the *i*-th filter in the vertical direction. The value of `ver_filter_coeff[i][j]` shall be in the range of $-2^{31} + 1$ to $2^{31} - 1$, inclusive.

The variable `verTapLength[]` is derived as follows:

- If `ver_chroma_filter_idc` is equal to 1, `verTapLength[i]` is set equal to `ver_tap_length_minus1[i]` plus 1 for *i* in the range of 0..`num_vertical_filters` – 1.
- Otherwise (`ver_chroma_filter_idc` is equal to 2), the value of `verTapLength[]` is derived as specified in Table D.18.

The variable `verFilterCoeff[i][j]` is derived as follows:

- If `ver_chroma_filter_idc` is equal to 1, `verFilterCoeff[i][j]` is set equal to `ver_filter_coeff[i][j]` for *i* in the range of 0..`num_vertical_filters` – 1, inclusive, and *j* in the range of 0..`ver_tap_length_minus1[i]`, inclusive.
- Otherwise (`ver_chroma_filter_idc` is equal to 2), the values of `verFilterCoeff[][]` are derived as specified in Table D.18.

num_horizontal_filters specifies the number of filters indicated for chroma downsampling and upsampling in the horizontal direction. When `hor_chroma_filter_idc` is equal to 1, depending on the value of `chromaSampleLocType`, the value of `num_horizontal_filters` shall be equal to the values specified in Table D.17.

Table D.17 – Constraints on the value of num_horizontal_filters

chromaSampleLocType	Mandatory value of num_horizontal_filters
0, 2, 4	3
1, 3, 5	2

hor_tap_length_minus1[i] plus 1 specifies the length of the *i*-th filter in the horizontal direction. The value of `hor_tap_length_minus1[i]` shall be in the range of 0 to 31, inclusive.

hor_filter_coeff[i][j] specifies the value of the *j*-th coefficient of the *i*-th filter in the horizontal direction. The value of `hor_filter_coeff[i][j]` shall be in the range of $-2^{31} + 1$ to $2^{31} - 1$, inclusive.

The variable `horTapLength[]` is derived as follows:

- If `hor_chroma_filter_idc` is equal to 1, `horTapLength[i]` is set equal to `hor_tap_length_minus1[i]` plus 1 for *i* in the range of 0 to `num_horizontal_filters` – 1, inclusive.

- Otherwise (hor_chroma_filter_idc is equal to 2), the values of horTapLength[] are derived as specified in Table D.19.

The variable horFilterCoeff[][] is derived as follows:

- If hor_chroma_filter_idc is equal to 1, horFilterCoeff[i][j] is set equal to hor_filter_coeff[i][j] for i in the range of 0 to num_horizontal_filters – 1, inclusive, and j in the range of 0 to hor_tap_length_minus1[i], inclusive.
- Otherwise (hor_chroma_filter_idc is equal to 2), the values of horFilterCoeff[][] are derived as specified in Table D.19.

Table D.18 specifies the coefficients of the sets of chroma downsampling and upsampling filters in the vertical direction when ver_chroma_filter_idc is equal to 2.

NOTE 2 – When ver_chroma_filter_idc is equal to 2, the filter coefficient values specified in Table D.18 correspond to those described in SMPTE RP 2050-1 (2012).

Table D.19 specifies the coefficients of the sets of chroma downsampling and upsampling filters in the horizontal direction when hor_chroma_filter_idc is equal to 2.

NOTE 3 – When hor_chroma_filter_idc is equal to 2, the filter coefficient values specified in Table D.19 correspond to those described in the 5/3 filter specification part of Rec. ITU-T T.800 | ISO/IEC 15444-1.

Table D.18 – Values of verFilterCoeff and verTapLength when ver_chroma_filter_idc is equal to 2

chromaSampleLocType	ver_filtering_field_processing_flag	upsamplingFlag	verFilterCoeff[][]	verTapLength[]
0, 1	0	0	verFilterCoeff[0][] = { -3, -19, 34, 500, 500, 34, -19, -3 }	verTapLength[0] = 8
		1	verFilterCoeff[1][] = { 19, 103, 1037, -135 }	verTapLength[1] = 4
	1	0	verFilterCoeff[0][] = { -8, -26, 115, 586, 409, -48, -4, 0 }	verTapLength[0] = 8
		1	verFilterCoeff[1][] = { 24, -41, 1169, -128 }	verTapLength[1] = 4
			verFilterCoeff[2][] = { -76, 783, 330, -13 }	verTapLength[2] = 4

Table D.19 – Values of horFilterCoeff and horTapLength when hor_chroma_filter_idc is equal to 2

chromaSampleLocType	upsamplingFlag	horFilterCoeff[][]	horTapLength[]
0, 2, 4	0	horFilterCoeff[0][] = { -1, 2, 6, 2, -1 }	horTapLength[0] = 5
	1	horFilterCoeff[1][] = { 1 }	horTapLength[1] = 1
		horFilterCoeff[2][] = { 1, 1 }	horTapLength[2] = 2

The chroma resampling filtering process is applied as follows:

- The variable bottomFlag is derived as follows:
 - If field_seq_flag is equal to 1 and pic_struct is equal to 2, 10 or 12, bottomFlag is set equal to 1.
 - Otherwise, if field_seq_flag is equal to 0 and ver_filtering_field_processing_flag is equal to 1 and the output field being processed is a bottom field, bottomFlag is set equal to 1.
 - Otherwise, bottomFlag is set equal to 0.
- The variables phaseOffsetUp and phaseOffsetDown are derived as follows:
 - If bottomFlag is equal to 1, phaseOffsetUp is set equal to 2 and phaseOffsetDown is set equal to 1.
 - Otherwise (bottomFlag is equal to 0), phaseOffsetUp is set equal to 0 and phaseOffsetDown is set equal to 0.
- The vertical downsampling and upsampling filter coefficients fDv[] and fUv[] are specified in Table D.20.
- The horizontal downsampling and upsampling filter coefficients fDh[] and fUh[] are specified in Table D.21.
- The vertical downsampling and upsampling filter tap lengths lenDv[] and lenUv[] are specified in Table D.20.
- The horizontal downsampling and upsampling filter tap lengths lenDh[] and lenUh[] are specified in Table D.21.
- When chroma_format_idc is equal to 1 and target_format_idc is equal to either 2 or 3, the chroma upsampling filtering process in the vertical direction is applied once on the Cb samples and once on the Cr samples of the decoded cropped output picture as follows:
 - The variables w0 and h0 are derived as follows:

$$\begin{aligned} w0 &= (\text{pic_width_in_luma_samples} / \text{SubWidthC}) - (\text{conf_win_right_offset} + \text{conf_win_left_offset}) \\ h0 &= (\text{pic_height_in_luma_samples} \gg 1) - (\text{conf_win_top_offset} + \text{conf_win_bottom_offset}) \end{aligned} \quad (\text{D-44})$$

- Let p0X[i][j], with i in the range of 0 to w0 – 1, inclusive, j in the range of 0 to h0 – 1, inclusive, and X being either Cb or Cr, be the input array of Cb or Cr chroma samples from the decoded cropped output picture, and p1X[i][j], with i in the range of 0 to w0 – 1, inclusive, j in the range of 0 to (h0 << 1) – 1, inclusive, and X being either Cb or Cr, be the output array of Cb or Cr chroma samples of the vertical chroma upsampling process.

```

divUv[ 0 ] = 0
divUv[ 1 ] = 0
for( j = 0; j < lenUv[ phaseOffsetUp ]; j++ )
    divUv[ 0 ] += fUv[ phaseOffsetUp ][ j ]
for( j = 0; j < lenUv[ 1 + phaseOffsetUp ]; j++ )
    divUv[ 1 ] += fUv[ 1 + phaseOffsetUp ][ j ]
for( u = 0; u < w0; u++ )
    for( v = 0; v < ( h0 << 1 ); v++ ) {
        sum = 0
        posOffsetUp = v % 2 + phaseOffsetUp
        for( j = - ( lenUv[ posOffsetUp ] - 1 ) / 2; j <= lenUv[ posOffsetUp ] / 2; j++ ) {
            sum += p0X[ u ][ Clip3( 0, h0 - 1, ( v >> 1 ) + j ) ]
                * fUv[ posOffsetUp ][ j + ( lenUv[ posOffsetUp ] - 1 ) / 2 ]
        }
        p1X[ u ][ v ] = ( sum + ( divUv[ v % 2 ] >> 1 ) ) / divUv[ v % 2 ]
    }

```

(D-45)

- When ver_filtering_field_process_flag is equal to 1 and field_seq_flag is equal to 0, the chroma upsampling filtering process in the vertical direction is applied to each field of the Cb or Cr chroma components of the cropped output frame picture p0X[i][j], with i in the range of 0 to w0 – 1, inclusive, j in the range of 0 to h0 – 1, inclusive, and X being either Cb or Cr. The following ordered steps apply:
 1. The array p0X is deinterleaved into two fields, p0XTop with height being equal to h0 >> 1 and p0XBottom with height being equal to h0 – (h0 >> 1).
 2. The chroma upsampling filtering process in the vertical direction according to Equation D-45 is applied to p0XTop and p0XBottom to derive the output of the filtering process p1XTop and p1XBottom.
 3. The arrays p1XTop and p1XBottom are interleaved to form the output array p1X of the upsampling filtering process.
- When chroma_format_idc is equal to either 1 or 2 and target_format_idc is equal to 3, the chroma upsampling filtering process in the horizontal direction is applied once on the Cb samples and once on the Cr samples of the decoded picture as follows:

- The variables $w0$ and $h0$ are derived as follows:

$$\begin{aligned} h0 &= (\text{pic_height_in_luma_samples} / \text{SubHeightC}) - (\text{conf_win_top_offset} + \text{conf_win_bottom_offset}) \\ w0 &= (\text{pic_width_in_luma_samples} \gg 1) - (\text{conf_win_right_offset} + \text{conf_win_left_offset}) \end{aligned} \quad (\text{D-46})$$

- Let $p0X[i][j]$, with i in the range of 0 to $w0 - 1$, inclusive, j in the range of 0 to $h0 - 1$, inclusive, and X being either Cb or Cr, be the input array of Cb or Cr chroma samples from the decoded cropped output picture, and $p1X[i][j]$, with i in the range of 0 to $(w0 \ll 1) - 1$, inclusive, j in the range of 0 to $h0 - 1$, inclusive and X being either Cb or Cr, be the output array of Cb or Cr chroma samples of the horizontal chroma upsampling process.

```
divUh[ 0 ] = 0
divUh[ 1 ] = 0
for( j = 0; j < lenUh[ 0 ]; j++ )
    divUh[ 0 ] += fUh[ 0 ][ j ]
for( j = 0; j < lenUh[ 1 ]; j++ )
    divUh[ 1 ] += fUh[ 1 ][ j ]
for( v = 0; v < h0; v++ )
    for( u = 0; u < ( w0 << 1 ); u++ ) {
        sum = 0
        for( i = -( lenUh[ u % 2 ] - 1 ) / 2; i <= lenUh[ u % 2 ] / 2; i++ )
            sum += p0X[ Clip3( 0, w0 - 1, ( u >> 1 ) + i ) ][ v ] * fUh[ u % 2 ][ i + ( lenUh[ u % 2 ] - 1 ) / 2 ]
        p1X[ u ][ v ] = ( sum + ( divUh[ u % 2 ] >> 1 ) ) / divUh[ u % 2 ]
    }
```

(D-47)

- When chroma_format_idc is equal to either 3 or 2 and target_format_idc is equal to 1, the chroma downsampling filtering process in the vertical direction is applied once on the Cb samples and once on the Cr samples of the decoded picture as follows:

- The variables $w0$ and $h0$ are derived as follows:

$$\begin{aligned} w0 &= (\text{pic_width_in_luma_samples} / \text{SubWidthC}) - (\text{conf_win_right_offset} + \text{conf_win_left_offset}) \\ h0 &= \text{pic_height_in_luma_samples} - (\text{conf_win_top_offset} + \text{conf_win_bottom_offset}) \end{aligned} \quad (\text{D-48})$$

- Let $p0X[i][j]$, with i in the range of 0 to $w0 - 1$, inclusive, j in the range of 0 to $h0 - 1$, inclusive, and X being either Cb or Cr, be the input array of Cb or Cr chroma samples from the decoded cropped output picture, and $p1X[i][j]$, with i in the range of 0 to $w0 - 1$, inclusive, j in the range of 0 to $(h0 \gg 1) - 1$, inclusive, and X being either Cb or Cr, be the output array of Cb or Cr chroma samples of the vertical chroma downsampling process.

```
divDv = 0
for( j = 0; j < lenDv[ phaseOffsetDown ]; j++ )
    divDv += fDv[ phaseOffsetDown ][ j ]
for( u = 0; u < w0; u++ )
    for( v = 0; v < ( h0 >> 1 ); v++ ) {
        sum = 0
        for( j = -( lenDv[ phaseOffsetDown ] - 1 ) / 2; j <= lenDv[ phaseOffsetDown ] / 2; j++ )
            sum += p0X[ u ][ Clip3( 0, h0 - 1, ( v << 1 ) + j ) ]
                * fDv[ phaseOffsetDown ][ j + ( lenDv[ phaseOffsetDown ] - 1 ) / 2 ]
        p1X[ u ][ v ] = ( sum + ( divDv >> 1 ) ) / divDv
    }
```

(D-49)

- When $\text{ver_filtering_field_process_flag}$ is equal to 1 and field_seq_flag is equal to 0, the chroma downsampling filtering process in the vertical direction is applied to each field of each of the Cb and Cr chroma components of the cropped output frame picture $p0X[i][j]$, with i in the range of 0 to $w0 - 1$, inclusive, j in the range of 0 to $h0 - 1$, inclusive, and X being either Cb or Cr. The following ordered steps apply:

1. The array $p0X$ is deinterleaved into two fields, $p0X_{\text{Top}}$ with height being equal to $h0 \gg 1$ and $p0X_{\text{Bottom}}$ with height being equal to $h0 - (h0 \gg 1)$.
2. The chroma downsampling filtering process in the vertical direction according to Equation D-49 is applied to $p0X_{\text{Top}}$ and $p0X_{\text{Bottom}}$ to derive the output of the filtering process $p1X_{\text{Top}}$ and $p1X_{\text{Bottom}}$.

3. The arrays p1XTop and p1XBottom are interleaved to form the output array p1X of the downsampling filtering process.

– When chroma_format_idc is equal to 3 and target_format_idc is equal to either 1 or 2, the chroma downsampling filtering process in the horizontal direction is applied once on the Cb samples and once on the Cr samples of the decoded picture as follows:

– The variables w0 and h0 are derived as follows:

$$\begin{aligned} h0 &= (\text{pic_height_in_luma_samples} / \text{SubHeightC}) - (\text{conf_win_top_offset} + \text{conf_win_bottom_offset}) \\ w0 &= \text{pic_width_in_luma_samples} - (\text{conf_win_right_offset} + \text{conf_win_left_offset}) \end{aligned} \quad (\text{D-50})$$

– Let p0X[i][j], with i in the range of 0 to w0 – 1, inclusive, j in the range of 0 to h0 – 1, inclusive, and X being either Cb or Cr, be the input array of Cb or Cr chroma samples from the decoded cropped output picture, and p1X[i][j], with i in the range of 0 to (w0 >> 1) – 1, inclusive, j in the range of 0 to h0 – 1, inclusive, and X being either Cb or Cr, be the output array of Cb or Cr chroma samples of the horizontal chroma downsampling process.

```
divUh = 0
for( j = 0; j < lenDh; j++ )
    divDh += fDh[ 0 ][ j ]
for( v = 0; v < h0; v++ )
    for( u = 0; u < ( w0 >> 1 ); u++ ) {
        sum = 0
        for( i = -( lenDh - 1 ) / 2; i <= lenDh / 2; i++ )
            sum += p0X[ Clip3( 0, w0 - 1, ( u << 1 ) + i ) ][ v ] * fDh[ 0 ][ i + ( lenDh - 1 ) / 2 ]
        p1X[ u ][ v ] = ( sum + ( divDh >> 1 ) ) / divDh
    }
```

(D-51)

D.3.32 Knee function information SEI message semantics

The knee function information SEI message provides information to enable mapping of the colour samples of decoded pictures for customisation to particular display environments. The process uses a knee function to map the white level of sample values in the normalized linear RGB colour space to an appropriate luminance level and should be applied to each RGB component produced by the colour space conversion of a decoded image.

A knee function is a piece-wise linear function that starts with the point (0.0, 0.0), ends with the point (1.0, 1.0) and is specified by knee points in ascending order of index i . The coordinate of the i -th knee point is specified by ($\text{input_knee_point}[i] \div 1\,000$, $\text{output_knee_point}[i] \div 1\,000$). A knee function maps the input luminance level normalized in the range of 0.0 to 1.0 to the output luminance level normalized in the range of 0.0 to 1.0. An example of a knee function is shown in Figure D.11.

Figure D.11 – A knee function with `num_knee_points_minus1` equal to 2

knee_function_id contains an identifying number that may be used to identify the purpose of the knee functions. The value of `knee_function_id` shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of `knee_function_id` from 0 to 255, inclusive, and from 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of `knee_function_id` from 256 to 511, inclusive, and from 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `knee_function_id` in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

NOTE 1 – The `knee_function_id` can be used to support knee function processes that are suitable for different display scenarios. For example, different values of `knee_function_id` may correspond to different display bit depths.

knee_function_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous knee function information SEI message in output order that applies to the current layer. `knee_function_cancel_flag` equal to 0 indicates that knee function information follows.

knee_function_persistence_flag specifies the persistence of the knee function information SEI message for the current layer.

`knee_function_persistence_flag` equal to 0 specifies that the knee function information applies to the current decoded picture only.

Let `picA` be the current picture. `knee_function_persistence_flag` equal to 1 specifies that the knee function information persists for the current layer in output order until any of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture `picB` in the current layer in an access unit containing a knee function information SEI message with the same value of `knee_function_id` and applicable to the current layer is output for which `PicOrderCnt(picB)` is greater

than `PicOrderCnt(picA)`, where `PicOrderCnt(picB)` and `PicOrderCnt(picA)` are the `PicOrderCntVal` values of `picB` and `picA`, respectively, immediately after the invocation of the decoding process for picture order count for `picB`.

input_d_range specifies the peak luminance level for the input picture of the knee function process relative to the nominal luminance level in units of 0.1%. When the value of `input_d_range` is equal to 0, the peak luminance level of the input picture is unspecified.

input_disp_luminance specifies the expected display brightness of peak luminance level for the input picture of the knee function process. The value of `input_disp_luminance` is in units of candelas per square metre. When the value of `input_disp_luminance` is equal to 0, the expected display brightness of peak luminance level for the input picture is unspecified.

output_d_range specifies the peak luminance level for the output picture of the knee function process relative to the nominal luminance level in units of 0.1%. When the value of `output_d_range` is equal to 0, the peak luminance level of the output picture is unspecified.

output_disp_luminance specifies the expected display brightness of peak luminance level for the output picture of the knee function process. The value of `output_disp_luminance` is in units of candelas per square metre. When the value of `output_disp_luminance` is equal to 0, the expected display brightness of peak luminance level for the output picture is unspecified.

num_knee_points_minus1 plus 1 specifies the number of knee points used to define the knee function. `num_knee_points_minus1` shall be in the range of 0 to 998, inclusive.

input_knee_point[i] specifies the luminance level of the *i*-th knee point of the input picture. The luminance level of the knee point of the input picture is normalized to the range of 0 to 1.0 in units of 0.1%. The value of `input_knee_point[i]` shall be in the range of 1 to 999, inclusive. The value of `input_knee_point[i]` shall be greater than the value of `input_knee_point[i - 1]`, for *i* in the range of 1 to `num_knee_points_minus1`, inclusive.

output_knee_point[i] specifies the luminance level of the *i*-th knee of the output picture. The luminance level of the knee point of the output picture is normalized to the range of 0 to 1.0 in units of 0.1%. The value of `output_knee_point[i]` shall be in the range of 0 to 1 000, inclusive. The value of `output_knee_point[i]` shall be greater than or equal to the value of `output_knee_point[i - 1]`, for *i* in the range of 1 to `num_knee_points_minus1`, inclusive.

NOTE 2 – The luminance level conversion process between an input signal *x* and an output signal *y*, where the luminance levels for both input and output are normalized to be in the range of 0.0 to 1.0, is specified as follows:

```

if( x <= input_knee_point[ 0 ] ÷ 1 000 )
    y = ( output_knee_point[ 0 ] ÷ input_knee_point[ 0 ] ) * x
else if( x > input_knee_point[ num_knee_points_minus1 ] )
    y = ( ( 1 000 - output_knee_point[ num_knee_points_minus1 ] ) ÷
          ( 1 000 - input_knee_point[ num_knee_points_minus1 ] ) ) *
          ( x - input_knee_point[ num_knee_points_minus1 ] ÷ 1 000 ) +
          ( output_knee_point[ num_knee_points_minus1 ] ÷ 1 000 )
else
    for( i = 1; i <= num_knee_points_minus1; i++ )
        if( input_knee_point[ i - 1 ] ÷ 1 000 < x && x <= input_knee_point[ i ] ÷ 1 000 )
            y = ( ( output_knee_point[ i ] - output_knee_point[ i - 1 ] ) ÷
                  ( input_knee_point[ i ] - input_knee_point[ i - 1 ] ) ) *
                  ( x - input_knee_point[ i - 1 ] ÷ 1 000 ) + ( output_knee_point[ i - 1 ] ÷ 1 000 )

```

(D-52)

D.3.33 Colour remapping information SEI message semantics

The colour remapping information SEI message provides information to enable remapping of the reconstructed colour samples of the output pictures for purposes such as converting the output pictures to a representation that is more suitable for an alternative display. The colour remapping model used in the colour remapping information SEI message is composed of a first piece-wise linear function applied to each colour component (specified by the "pre" set of syntax elements herein), followed by a three-by-three matrix applied to the three resulting colour components, followed by a second piece-wise linear function applied to each resulting colour component (specified by the "post" set of syntax elements herein).

NOTE 1 – Colour remapping of the output pictures for the display process (which is outside the scope of this Specification) is optional and does not affect the decoding process specified in this Specification.

Unless indicated otherwise by some means not specified in this Specification, the input to the indicated remapping process is the set of decoded sample values after applying an (unspecified) upsampling conversion process to the 4:4:4 colour sampling format as necessary when the colour remapping three-by-three matrix coefficients are present in the SEI message and `chroma_format_idc` is equal to 1 (4:2:0 chroma format) or 2 (4:2:2 chroma format). When `chroma_format_idc` is equal to 0 (monochrome), the colour remapping information SEI message shall not be present, although decoders shall allow such messages to be present and shall ignore any such colour remapping information SEI messages that may be present.

colour_remap_id contains an identifying number that may be used to identify the purpose of the colour remapping information. The value of colour_remap_id may be used (in a manner not specified in this Specification) to indicate that the input to the remapping process is the output of some conversion process that is not specified in this Specification, such as a conversion of the picture to some alternative colour representation (e.g., conversion from a YCbCr colour representation to a GBR colour representation). When more than one colour remapping information SEI message is present with the same value of colour_remap_id, the content of these colour remapping information SEI messages shall be the same. When colour remapping information SEI messages are present that have more than one value of colour_remap_id, this may indicate that the remapping processes indicated by the different values of colour_remap_id are alternatives that are provided for different purposes or that a cascading of remapping processes is to be applied in a sequential order (an order that is not specified in this Specification). The value of colour_remap_id shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of colour_remap_id from 0 to 255, inclusive, and from 512 to $2^{31} - 1$, inclusive, may be used as determined by the application. Values of colour_remap_id from 256 to 511, inclusive, and from 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of colour_remap_id in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

NOTE 2 – The colour_remap_id can be used to support different colour remapping processes that are suitable for different display scenarios. For example, different values of colour_remap_id may correspond to different remapped colour spaces supported by displays.

colour_remap_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous colour remapping information SEI message in output order that applies to the current layer. colour_remap_cancel_flag equal to 0 indicates that colour remapping information follows.

colour_remap_persistence_flag specifies the persistence of the colour remapping information SEI message for the current layer.

colour_remap_persistence_flag equal to 0 specifies that the colour remapping information applies to the current picture only.

Let picA be the current picture. colour_remap_persistence_flag equal to 1 specifies that the colour remapping information persists for the current layer in output order until either of the following conditions is true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture picB in the current layer in an access unit containing a colour remapping information SEI message with the same value of colour_remap_id and applicable to the current layer is output for which PicOrderCnt(picB) is greater than PicOrderCnt(picA), where PicOrderCnt(picB) and PicOrderCnt(picA) are the PicOrderCntVal values of picB and picA, respectively, immediately after the invocation of the decoding process for picture order count for picB.

colour_remap_video_signal_info_present_flag equal to 1 specifies that syntax elements colour_remap_full_range_flag, colour_remap_primaries, colour_remap_transfer_function and colour_remap_matrix_coefficients are present, colour_remap_video_signal_info_present_flag equal to 0 specifies that syntax elements colour_remap_full_range_flag, colour_remap_primaries, colour_remap_transfer_function and colour_remap_matrix_coefficients are not present.

colour_remap_full_range_flag has the same semantics as specified in clause E.3.1 for the video_full_range_flag syntax element, except that colour_remap_full_range_flag identifies the colour space of the remapped reconstructed picture, rather than the colour space used for the CLVS. When not present, the value of colour_remap_full_range_flag is inferred to be equal to the value of video_full_range_flag.

colour_remap_primaries has the same semantics as specified in clause E.3.1 for the colour_primaries syntax element, except that colour_remap_primaries identifies the colour space of the remapped reconstructed picture, rather than the colour space used for the CLVS. When not present, the value of colour_remap_primaries is inferred to be equal to the value of colour_primaries.

colour_remap_transfer_function has the same semantics as specified in clause E.3.1 for the transfer_characteristics syntax element, except that colour_remap_transfer_function identifies the colour space of the remapped reconstructed picture, rather than the colour space used for the CLVS. When not present, the value of colour_remap_transfer_function is inferred to be equal to the value of transfer_characteristics.

colour_remap_matrix_coefficients has the same semantics as specified in clause E.3.1 for the matrix_coeffs syntax element, except that colour_remap_matrix_coefficients identifies the colour space of the remapped reconstructed picture, rather than the colour space used for the CLVS. When not present, the value of colour_remap_matrix_coefficients is inferred to be equal to the value of matrix_coeffs.

colour_remap_input_bit_depth specifies the bit depth of the colour components of the associated pictures for purposes of interpretation of the colour remapping information SEI message. When any colour remapping information SEI message is present with the value of colour_remap_input_bit_depth not equal to the bit depth of the decoded colour components,

the SEI message refers to the hypothetical result of a conversion operation performed to convert the decoded colour component samples to the bit depth equal to colour_remap_input_bit_depth.

The value of colour_remap_input_bit_depth shall be in the range of 8 to 16, inclusive. Values of colour_remap_input_bit_depth from 0 to 7, inclusive, and from 17 to 255, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore all colour remapping SEI messages that contain a colour_remap_input_bit_depth in the range of 0 to 7, inclusive, or in the range of 17 to 255, inclusive, and bitstreams shall not contain such values.

colour_remap_output_bit_depth specifies the bit depth of the output of the colour remapping function described by the colour remapping information SEI message.

The value of colour_remap_output_bit_depth shall be in the range of 8 to 16, inclusive. Values of colour_remap_output_bit_depth from 0 to 7, inclusive, and in the range of 17 to 255, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore all colour remapping SEI messages that contain a value of colour_remap_output_bit_depth from 0 to 7, inclusive, or in the range of 17 to 255, inclusive, and bitstreams shall not contain such values.

pre_lut_num_val_minus1[c] plus 1 specifies the number of pivot points in the piece-wise linear remapping function for the c-th component, where c equal to 0 refers to the luma or G component, c equal to 1 refers to the Cb or B component and c equal to 2 refers to the Cr or R component. When pre_lut_num_val_minus1[c] is equal to 0, the default end points of the input values are 0 and $2^{\text{colour_remap_input_bit_depth}} - 1$, and the corresponding default end points of the output values are 0 and $2^{\text{colour_remap_output_bit_depth}} - 1$, for the c-th component. In bitstreams conforming to this version of this Specification, the value of pre_lut_num_val_minus1[c] shall be in the range of 0 to 32, inclusive.

pre_lut_coded_value[c][i] specifies the input value of the i-th pivot point for the c-th component. The number of bits used to represent pre_lut_coded_value[c][i] is $((\text{colour_remap_input_bit_depth} + 7) \gg 3) \ll 3$.

pre_lut_target_value[c][i] specifies the output value of the i-th pivot point for the c-th component. The number of bits used to represent pre_lut_target_value[c][i] is $((\text{colour_remap_output_bit_depth} + 7) \gg 3) \ll 3$.

When pre_lut_coded_value[c][0] is greater than 0, an initial linear segment should be inferred that maps input values ranging from 0 to pre_lut_coded_value[c][0], inclusive, to target values ranging from 0 to pre_lut_target_value[c][0], inclusive.

When pre_lut_coded_value[c][pre_lut_num_val_minus1[c]] is not equal to $2^{\text{colour_remap_input_bit_depth}} - 1$, a final linear segment should be inferred that maps input values ranging from pre_lut_coded_value[c][pre_lut_num_val_minus1[c]] to $2^{\text{colour_remap_input_bit_depth}} - 1$, inclusive, to target values ranging from pre_lut_target_value[c][pre_lut_num_val_minus1[c]] to $2^{\text{colour_remap_output_bit_depth}} - 1$, inclusive.

colour_remap_matrix_present_flag equal to 1 indicates that the syntax elements log2_matrix_denom and colour_remap_coeffs[c][i], for c and i in the range of 0 to 2, inclusive, are present. colour_remap_matrix_present_flag equal to 0 indicates that the syntax elements log2_matrix_denom and colour_remap_coeffs[c][i], for c and i in the range of 0 to 2, inclusive, are not present.

log2_matrix_denom specifies the base 2 logarithm of the denominator for all matrix coefficients. The value of log2_matrix_denom shall be in the range of 0 to 15, inclusive. When not present, the value of log2_matrix_denom is inferred to be equal to 0.

colour_remap_coeffs[c][i] specifies the value of the three-by-three colour remapping matrix coefficients. The value of colour_remap_coeffs[c][i] shall be in the range of -2^{15} to $2^{15} - 1$, inclusive. When colour_remap_coeffs[c][i] is not present, it is inferred to be equal to 1 if c is equal to i, and inferred to be equal to 0 otherwise.

NOTE 3 – When colour_remap_matrix_present_flag is equal to 0, the colour remapping matrix is inferred to be equal to the identity matrix of size 3x3.

The variable matrixOutput[c] for c = 0, 1 and 2 is derived as follows:

```
roundingOffset = log2_matrix_denom == 0 ? 0 : 1 << ( log2_matrix_denom - 1 )
matrixOutput[ c ] = Clip3( 0, ( 1 << colour_remap_output_bit_depth ) - 1,
    ( colour_remap_coeffs[ c ][ 0 ] * matrixInput[ 0 ] + colour_remap_coeffs[ c ][ 1 ] * matrixInput[ 1 ]
    + colour_remap_coeffs[ c ][ 2 ] * matrixInput[ 2 ] + roundingOffset ) >> log2_matrix_denom )
(D-53)
```

where matrixInput[c] is the input sample value of the c-th colour component and matrixOutput[c] is the output sample value of the c-th colour component.

post_lut_num_val_minus1[c] has the same semantics as pre_lut_num_val_minus1[c], with "pre" replaced by "post", except that the default end points of the input values are 0 and $2^{\text{colour_remap_output_bit_depth}} - 1$ for the c-th colour component. The value of post_lut_num_val_minus1[c] shall be in the range of 0 to 32, inclusive.

post_lut_coded_value[c][i] has the same semantics as **pre_lut_coded_value**[c][i], with "pre" replaced by "post", except that the number of bits used to represent **post_lut_coded_value**[c][i] is $((\text{colour_remap_output_bit_depth} + 7) \gg 3) \ll 3$.

post_lut_target_value[c][i] has the same semantics as **pre_lut_target_value**[c][i], with "pre" replaced by "post" except that **colour_remap_input_bit_depth** is replaced by **colour_remap_output_bit_depth** in the semantics.

D.3.34 Deinterlaced field identification SEI message semantics

The deinterlaced picture information SEI message indicates that the current picture represents a frame that was interpolated via a deinterlacing process prior to encoding, and indicates the field parity of the associated source field prior to the deinterlacing process. When a progressive-to-interlace conversion process is applied to the decoded picture prior to display, it is recommended that the field of the decoded frame with the indicated field parity should be used.

When the value of **field_seq_flag** of any active SPS for any picture in the current access unit is equal to 1, the deinterlaced field identification SEI message shall not be present.

deinterlaced_picture_source_parity_flag equal to 0 indicates that the current picture was deinterlaced using a top field picture as the associated source field. **deinterlaced_picture_source_parity_flag** equal to 1 indicates that the current picture was deinterlaced using a bottom field picture as the associated source field.

D.3.35 Content light level information SEI message semantics

This SEI message identifies upper bounds for the nominal target brightness light level of the pictures of the CLVS.

The information conveyed in this SEI message is intended to be adequate for purposes corresponding to the use of the Consumer Electronics Association 861.3 specification.

The semantics of the content light level information SEI message are defined in relation to the values of samples in a 4:4:4 representation of red, green, and blue colour primary intensities in the linear light domain for the pictures of the CLVS, in units of candelas per square metre. However, this SEI message does not, by itself, identify a conversion process for converting the sample values of a decoded picture to the samples in a 4:4:4 representation of red, green, and blue colour primary intensities in the linear light domain for the picture.

NOTE 1 – Other syntax elements, such as **colour primaries**, **transfer characteristics**, **matrix coeffs**, and the chroma resampling filter hint SEI message, when present, may assist in the identification of such a conversion process.

Given the red, green, and blue colour primary intensities in the linear light domain for the location of a luma sample in a corresponding 4:4:4 representation, denoted as E_R , E_G , and E_B , the maximum component intensity is defined as $E_{\text{Max}} = \text{Max}(E_R, \text{Max}(E_G, E_B))$. The light level corresponding to the stimulus is then defined as the CIE 1931 luminance corresponding to equal amplitudes of E_{Max} for all three colour primary intensities for red, green, and blue (with appropriate scaling to reflect the nominal luminance level associated with peak white – e.g., ordinarily scaling to associate peak white with 10 000 candelas per square metre when **transfer_characteristics** is equal to 16).

NOTE 2 – Since the maximum value E_{Max} is used in this definition at each sample location, rather than a direct conversion from E_R , E_G , and E_B to the corresponding CIE 1931 luminance, the CIE 1931 luminance at a location may in some cases be less than the indicated light level. This situation would occur, for example, when E_R and E_G are very small and E_B is large, in which case the indicated light level would be much larger than the true CIE 1931 luminance associated with the (E_R, E_G, E_B) triplet.

All content light level information SEI messages that apply to the same CLVS shall have the same content.

max_content_light_level, when not equal to 0, indicates an upper bound on the maximum light level among all individual samples in a 4:4:4 representation of red, green, and blue colour primary intensities (in the linear light domain) for the pictures of the CLVS, in units of candelas per square metre. When equal to 0, no such upper bound is indicated by **max_content_light_level**.

max_pic_average_light_level, when not equal to 0, indicates an upper bound on the maximum average light level among the samples in a 4:4:4 representation of red, green, and blue colour primary intensities (in the linear light domain) for any individual picture of the CLVS, in units of candelas per square metre. When equal to 0, no such upper bound is indicated by **max_pic_average_light_level**.

NOTE 3 – When the visually relevant region does not correspond to the entire cropped decoded picture, such as for "letterbox" encoding of video content with a wide picture aspect ratio within a taller cropped decoded picture, the indicated average should be performed only within the visually relevant region.

D.3.36 Dependent random access point indication SEI message semantics

The picture associated with a dependent random access point indication SEI message is referred to as a DRAP picture.

The presence of the dependent random access point indication SEI message indicates that the constraints on picture order and picture referencing specified in this clause apply. These constraints can enable a decoder to properly decode the DRAP

picture and the pictures that follow it in both decoding order and output order without needing to decode any other pictures except the associated IRAP picture.

The constraints indicated by the presence of the dependent random access point indication SEI message are as follows:

- The DRAP picture shall be a TRAIL_R picture with TemporalId equal to 0 and nuh_layer_id equal to 0.
- The DRAP picture shall not include any pictures in its RPS lists RefPicSetStCurrBefore, RefPicSetStCurrAfter, and RefPicSetLtCurr except its associated IRAP picture.
- Any picture that follows the DRAP picture in both decoding order and output order shall not include, in its RPS, any picture that precedes the DRAP picture in decoding order or output order with the exception of the IRAP picture associated with the DRAP picture.

D.3.37 Coded region completion SEI message semantics

The coded region completion SEI message indicates the value of the slice_segment_address of the next slice segment in the bitstream (when present) and whether the next slice segment in the bitstream (when present) is an independent slice segment or a dependent slice segment. The term "next slice segment", here and below in this clause, refers to the next slice segment, in decoding order, after the VCL NAL unit associated with the SEI NAL unit containing the coded region completion SEI message.

NOTE – The coded region completion SEI message may be used in determining that a complete slice, coded picture, or access unit has been received prior to receiving any VCL NAL unit of the next slice, coded picture, or access unit, respectively. Consequently, when an implementation of the decoding process expects a complete slice, coded picture, or access unit as input, the coded region completion SEI message may reduce the decoding latency.

next_segment_address identifies the value of the slice_segment_address of the next slice segment in the bitstream (when present). When the next slice segment has first_slice_segment_in_pic_flag equal to 1 or no subsequent slice segment is present in the bitstream, the value of next_segment_address shall be equal to 0.

independent_slice_segment_flag equal to 1 indicates that the next slice segment, when present, is an independent slice segment. independent_slice_segment_flag equal to 0 indicates that the next slice segment, when present, is a dependent slice segment. When independent_slice_segment_flag is not present, it is inferred to be equal to 1.

D.3.38 Alternative transfer characteristics SEI message semantics

The alternative transfer characteristics SEI message provides a preferred alternative value for the transfer_characteristics syntax element that is indicated by the colour description syntax of VUI parameters of the SPS. This SEI message is intended to be used in cases when some value of transfer_characteristics is preferred for interpretation of the pictures of the CLVS although some other value of transfer_characteristics may also be acceptable for interpretation of the pictures of the CLVS and that other value is provided in the colour description syntax of VUI parameters of the SPS for interpretation by decoders that do not support interpretation of the preferred value (e.g., because the preferred value had not yet been defined in a previous version of this Specification).

When an alternative transfer characteristics SEI message is present for any picture of a CLVS of a particular layer and the first picture of the CLVS is an IRAP picture, an alternative transfer characteristics SEI message shall be present for that IRAP picture. The alternative transfer characteristics SEI message persists for the current layer in decoding order from the current picture until the end of the CLVS. All alternative transfer characteristics SEI messages that apply to the same CLVS shall have the same content.

preferred_transfer_characteristics specifies a preferred alternative value for the transfer_characteristics syntax element of the colour description syntax of VUI parameters of the SPS. The semantics for preferred_transfer_characteristics are otherwise the same as for the transfer_characteristics syntax element specified in the VUI parameters of the SPS (see clause E.3.1 and Table E.4). When preferred_transfer_characteristics is not equal to the value of transfer_characteristics indicated in the VUI parameters of the SPS, decoders should ignore the value of transfer_characteristics indicated in the VUI parameters of the SPS and instead use the value indicated by preferred_transfer_characteristics.

D.3.39 Ambient viewing environment SEI message semantics

The ambient viewing environment SEI message identifies the characteristics of the nominal ambient viewing environment for the display of the associated video content. The syntax elements of the ambient viewing environment SEI message may assist the receiving system in adapting the received video content for local display in viewing environments that may be similar or may substantially differ from those assumed or intended when mastering the video content.

This SEI message does not provide information on colour transformations that would be appropriate to preserve creative intent on displays with colour volumes different from that of the described mastering display.

When an ambient viewing environment SEI message is present for any picture of a CLVS of a particular layer and the first picture of the CLVS is an IRAP picture, an ambient viewing environment SEI message shall be present for that IRAP

picture. The ambient viewing environment SEI message persists for the current layer in decoding order from the current picture until the end of the CLVS. All ambient viewing environment SEI messages that apply to the same CLVS shall have the same content.

ambient_illuminance specifies the environmental illuminance of the ambient viewing environment in units of 0.0001 lux. **ambient_illuminance** shall not be equal to 0.

ambient_light_x and **ambient_light_y** specify the normalized x and y chromaticity coordinates, respectively, of the environmental ambient light in the nominal viewing environment, according to the CIE 1931 definition of x and y as specified in ISO 11664-1 (see also ISO 11664-3 and CIE 15), in normalized increments of 0.00002. The values of **ambient_light_x** and **ambient_light_y** shall be in the range of 0 to 50 000, inclusive.

NOTE – For example, the conditions identified in Rec. ITU-R BT.2035 can be expressed using **ambient_illuminance** equal to 100 000 with background chromaticity indicating D_{65} (**ambient_light_x** equal to 15 635, **ambient_light_y** equal to 16 450), or optionally in some regions, background chromaticity indicating D_{93} (**ambient_light_x** equal to 14 155, **ambient_light_y** equal to 14 855).

D.3.40 Content colour volume SEI message semantics

The content colour volume SEI message describes the colour volume characteristics of the associated pictures. These colour volume characteristics are expressed in terms of a nominal range, although deviations from this range may occur.

The variable **transferCharacteristics** is specified as follows:

- If an alternative transfer characteristics SEI message is present for the CLVS, **transferCharacteristics** is set equal to **preferred_transfer_characteristics**;
- Otherwise, (an alternative transfer characteristics SEI message is not present for the CLVS), **transferCharacteristics** is set equal to **transfer_characteristics**.

The content colour volume SEI message shall not be present, and decoders shall ignore it, when any of the following conditions is true:

- Any of the values of **transferCharacteristics**, **colour_primaries**, and **matrix_coeffs** has a value defined as unspecified.
- The value of **transfer_characteristics** is equal to 2, 4, or 5.
- The value of **colour_primaries** is equal to 2.

The following applies when converting the signal from a non-linear to a linear representation:

- If the value of **transferCharacteristics** is equal to 1, 6, 7, 14, or 15, the Rec. ITU-R BT.1886-0 reference electro-optical transfer function should be used to convert the signal to its linear representation, where the value of screen luminance for white is set equal to 100 cd/m², the value of screen luminance for black is set equal to 0 cd/m², and the value of the exponent of the power function is set equal to 2.4.
- Otherwise, if the value of **transferCharacteristics** is equal to 18, the hybrid log-gamma reference electro-optical transfer function specified in Rec. ITU-R BT.2100-2 should be used to convert the signal to its linear representation, where the value of nominal peak luminance of the display is set equal to 1 000 cd/m², the value of the display luminance for black is set equal to 0 cd/m², and the value of system gamma is set equal to 1.2.
- Otherwise (the value of **transferCharacteristics** is not equal to 1, 6, 7, 14, 15, or 18) when the content colour volume SEI message is present, the exact inverse of the transfer function specified in Table E.4 should be used to convert the non-linear signal to a linear representation.

ccv_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous content colour volume SEI message in output order that applies to the current layer. **ccv_cancel_flag** equal to 0 indicates that content colour volume information follows.

ccv_persistence_flag specifies the persistence of the content colour volume SEI message for the current layer.

ccv_persistence_flag equal to 0 specifies that the content colour volume applies to the current decoded picture only.

Let **picA** be the current picture. **ccv_persistence_flag** equal to 1 specifies that the content colour volume SEI message persists for the current layer in output order until any of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture **picB** in the current layer in an access unit containing a content colour volume SEI message that is applicable to the current layer is output for which **PicOrderCnt(picB)** is greater than **PicOrderCnt(picA)**, where

PicOrderCnt(picB) and PicOrderCnt(picA) are the PicOrderCntVal values of picB and picA, respectively, immediately after the invocation of the decoding process for the picture order count of picB.

ccv_primaries_present_flag equal to 1 specifies that the syntax elements **ccv_primaries_x[c]** and **ccv_primaries_y[c]** are present. **ccv_primaries_present_flag** equal to 0 specifies that the syntax elements **ccv_primaries_x[c]** and **ccv_primaries_y[c]** are not present.

ccv_min_luminance_value_present_flag equal to 1 specifies that the syntax element **ccv_min_luminance_value** is present. **ccv_min_luminance_value_present_flag** equal to 0 specifies that the syntax element **ccv_min_luminance_value** is not present.

ccv_max_luminance_value_present_flag equal to 1 specifies that the syntax element **ccv_max_luminance_value** is present. **ccv_max_luminance_value_present_flag** equal to 0 specifies that the syntax element **ccv_max_luminance_value** is not present.

ccv_avg_luminance_value_present_flag equal to 1 specifies that the syntax element **ccv_avg_luminance_value** is present. **ccv_avg_luminance_value_present_flag** equal to 0 specifies that the syntax element **ccv_avg_luminance_value** is not present.

It is a requirement of bitstream conformance that the values of **ccv_primaries_present_flag**, **ccv_min_luminance_value_present_flag**, **ccv_max_luminance_value_present_flag**, and **ccv_avg_luminance_value_present_flag** shall not all be equal to 0.

ccv_reserved_zero_2bits[i] shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **reserved_zero_2bits[i]** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **reserved_zero_2bits[i]**.

ccv_primaries_x[c] and **ccv_primaries_y[c]** specify the normalized x and y chromaticity coordinates, respectively, of the colour primary component c of the nominal content colour volume, according to the CIE 1931 definition of x and y as specified in ISO 11664-1 (see also ISO 11664-3 and CIE 15), in normalized increments of 0.00002. For describing colour volumes that use red, green, and blue colour primaries, it is suggested that index value c equal to 0 should correspond to the green primary, c equal to 1 should correspond to the blue primary, and c equal to 2 should correspond to the red colour primary (see also Annex E and Table E.3).

The values of **ccv_primaries_x[c]** and **ccv_primaries_y[c]** shall be in the range of –5 000 000 to 5 000 000, inclusive.

When **ccv_primaries_x[c]** and **ccv_primaries_y[c]** are not present, they are inferred to be equal to the normalized x and y chromaticity coordinates, respectively, specified by **colour_primaries**.

ccv_min_luminance_value specifies the normalized minimum luminance value, according to CIE 1931, that is expected to be present in the content, where values are normalized to L_0 or L_c as specified in Table E.4 according to the indicated transfer characteristics of the signal. The values of **ccv_min_luminance_value** are in normalized increments of 0.0000001.

ccv_max_luminance_value specifies the maximum luminance value, according to CIE 1931, that is expected to be present in the content, where values are normalized to L_0 or L_c as specified in Table E.4 according to the transfer characteristics of the signal. The values of **ccv_max_luminance_value** are in normalized increments of 0.0000001.

ccv_avg_luminance_value specifies the average luminance value, according to CIE 1931, that is expected to be present in the content, where values are normalized to L_0 or L_c as specified in Table E.4 according to the transfer characteristics of the signal. The values of **ccv_avg_luminance_value** are in normalized increments of 0.0000001.

NOTE – The resulting domain from this conversion process may or may not represent light in a source or display domain – it is merely a gamut representation domain rather than necessarily being a representation of actual light in either the scene or display domain. Therefore, the values corresponding to **ccv_min_luminance_value**, **ccv_max_luminance_value**, and **ccv_avg_luminance_value** might not necessarily correspond to a true luminance value.

The value of **ccv_min_luminance_value**, when present, shall be less than or equal to **ccv_avg_luminance_value**, when present. The value of **ccv_avg_luminance_value**, when present, shall be less than or equal to **ccv_max_luminance_value**, when present. The value of **ccv_min_luminance_value**, when present, shall be less than or equal to **ccv_max_luminance_value**, when present.

When the visually relevant region does not correspond to the entire cropped decoded picture, such as for "letterbox" encoding of video content with a wide picture aspect ratio within a taller cropped decoded picture, the indicated **ccv_min_luminance_value**, **ccv_max_luminance_value**, and **ccv_avg_luminance_value** should correspond only to values within the visually relevant region.

D.3.41 Semantics of omnidirectional video specific SEI messages

D.3.41.1 Equirectangular projection SEI message semantics

The equirectangular projection SEI message provides information to enable remapping (through an equirectangular projection) of the colour samples of the projected pictures onto a sphere coordinate space in sphere coordinates (ϕ , θ) for use in omnidirectional video applications for which the viewing perspective is from the origin looking outward toward the inside of the sphere. The sphere coordinates are defined so that ϕ is the azimuth (longitude, increasing eastward) and θ is the elevation (latitude, increasing northward).

When an equirectangular projection SEI message is present for any picture of a CLVS of a particular layer, an equirectangular projection SEI message shall be present for the first picture of the CLVS and no SEI message indicating a different type of projection shall be present for any picture of the CLVS.

When `general_non_packed_constraint_flag` is equal to 1 in the active SPS for the current layer, there shall be no equirectangular projection SEI messages applicable for any picture of the CLVS of the current layer.

When `aspect_ratio_idc` is present and greater than 1 in the active SPS for the current layer, there should be no equirectangular projection SEI messages applicable for any picture of the CLVS of the current layer.

A frame packing arrangement SEI message for which all the following conditions are true is referred to as an effectively applicable frame packing arrangement SEI message:

- The value of `frame_packing_arrangement_cancel_flag` is equal to 0.
- The value of `frame_packing_arrangement_type` is equal to 3, 4, or 5.
- The value of `quincunx_sampling_flag` is equal to 0.
- The value of `spatial_flipping_flag` is equal to 0.
- The value of `field_views_flag` is equal to 0.
- The value of `frame0_grid_position_x` is equal to 0.
- The value of `frame0_grid_position_y` is equal to 0.
- The value of `frame1_grid_position_x` is equal to 0.
- The value of `frame1_grid_position_y` is equal to 0.

When a frame packing arrangement SEI message with `frame_packing_arrangement_cancel_flag` equal to 0 that applies to the picture is present that is not an effectively applicable frame packing arrangement SEI message, an equirectangular projection SEI message with `erp_cancel_flag` equal to 0 that applies to the picture shall not be present. Decoders shall ignore equirectangular projection SEI messages when a frame packing arrangement SEI message with `frame_packing_arrangement_cancel_flag` equal to 0 that applies to the picture is present that is not an effectively applicable frame packing arrangement SEI message.

When a segmented rectangular frame packing arrangement SEI message with `segmented_rect_frame_packing_arrangement_cancel_flag` equal to 0 is present that applies to the picture, an equirectangular projection SEI message with `erp_cancel_flag` equal to 0 shall not be present that applies to the picture. Decoders shall ignore equirectangular projection SEI messages when a segmented rectangular frame packing arrangement SEI message with `segmented_rect_frame_packing_arrangement_cancel_flag` equal to 0 is present that applies to the picture.

erp_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous equirectangular projection SEI message in output order. `erp_cancel_flag` equal to 0 indicates that equirectangular projection information follows.

erp_persistence_flag specifies the persistence of the equirectangular projection SEI message for the current layer.

`erp_persistence_flag` equal to 0 specifies that the equirectangular projection SEI message applies to the current decoded picture only.

Let `picA` be the current picture. `erp_persistence_flag` equal to 1 specifies that the equirectangular projection SEI message persists for the current layer in output order until one or more of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture `picB` in the current layer in an access unit containing an equirectangular projection SEI message that is applicable to the current layer is output for which `PicOrderCnt(picB)` is greater than `PicOrderCnt(picA)`, where

PicOrderCnt(picB) and PicOrderCnt(picA) are the PicOrderCntVal values of picB and picA, respectively, immediately after the invocation of the decoding process for picture order count for picB.

erp_guard_band_flag equal to 1 indicates that the constituent picture contains guard band areas for which the sizes are specified by the syntax elements **erp_left_guard_band_width** and **erp_right_guard_band_width**. **erp_guard_band_flag** equal to 0 indicates that the constituent picture does not contain guard band areas for which the sizes are specified by the syntax elements **erp_left_guard_band_width** and **erp_right_guard_band_width**.

erp_reserved_zero_2bits shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **erp_reserved_zero_2bits** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **erp_reserved_zero_2bits**.

erp_guard_band_type indicates the type of the guard bands as follows:

- **erp_guard_band_type** equal to 0 indicates that the content of the guard band in relation to the content of the constituent picture is unspecified.
- **erp_guard_band_type** equal to 1 indicates that the content of the guard band suffices for interpolation of sample values at sub-pel sample fractional locations within the constituent picture.

NOTE – **erp_guard_band_type** equal to 1 could be used when the boundary samples of a constituent picture have been copied horizontally to the guard band.

- **erp_guard_band_type** equal to 2 indicates that the content of the guard band represents actual picture content at a quality that gradually changes from the picture quality of the constituent picture to that of the spherically adjacent region.
- **erp_guard_band_type** equal to 3 indicates that the content of the guard bands represents actual picture content at a similar level of quality as the constituent picture.
- **erp_guard_band_type** values greater than 3 are reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value of **erp_guard_band_type** when the value is greater than 3 as equivalent to the value 0.

erp_left_guard_band_width specifies the width of the guard band on the left side of the constituent picture in units of luma samples. When **erp_guard_band_flag** is equal to 0, the value of **erp_left_guard_band_width** is inferred to be equal to 0. When **chroma_format_idc** is equal to 1 (4:2:0 chroma format) or 2 (4:2:2 chroma format), **erp_left_guard_band_width** shall be an even number.

erp_right_guard_band_width specifies the width of the guard band on the right side of the constituent picture in units of luma samples. When **erp_guard_band_flag** is equal to 0, the value of **erp_right_guard_band_width** is inferred to be equal to 0. When **chroma_format_idc** is equal to 1 (4:2:0 chroma format) or 2 (4:2:2 chroma format), **erp_right_guard_band_width** shall be an even number.

D.3.41.2 Cubemap projection SEI message semantics

The cubemap projection SEI message provides information to enable remapping (through a cubemap projection) of the colour samples of the projected pictures onto a sphere coordinate space in sphere coordinates (ϕ , θ) for use in omnidirectional video applications for which the viewing perspective is from the origin looking outward toward the inside of the sphere. The sphere coordinates are defined so that ϕ is the azimuth (longitude, increasing eastward) and θ is the elevation (latitude, increasing northward).

When a cubemap projection SEI message is present for any picture of a CLVS of a particular layer, a cubemap projection SEI message shall be present for the first picture of the CLVS and no SEI message indicating a different type of projection shall be present for any picture of the CLVS.

When **general_non_packed_constraint_flag** is equal to 1 in the active SPS for the current layer, there shall be no cubemap projection SEI messages applicable for any picture of the CLVS of the current layer.

When **aspect_ratio_idc** is present and greater than 1 in the active SPS for the current layer, there should be no cubemap projection SEI messages applicable for any picture of the CLVS of the current layer.

A frame packing arrangement SEI message for which all the following conditions are true is referred to as an effectively applicable frame packing arrangement SEI message:

- The value of **frame_packing_arrangement_cancel_flag** is equal to 0.
- The value of **frame_packing_arrangement_type** is equal to 3, 4, or 5.
- The value of **quincunx_sampling_flag** is equal to 0.
- The value of **spatial_flipping_flag** is equal to 0.

- The value of `field_views_flag` is equal to 0.
- The value of `frame0_grid_position_x` is equal to 0.
- The value of `frame0_grid_position_y` is equal to 0.
- The value of `frame1_grid_position_x` is equal to 0.
- The value of `frame1_grid_position_y` is equal to 0.

When a frame packing arrangement SEI message with `frame_packing_arrangement_cancel_flag` equal to 0 that applies to the picture is present that is not an effectively applicable frame packing arrangement SEI message, a cubemap projection SEI message with `cmp_cancel_flag` equal to 0 that applies to the picture shall not be present. Decoders shall ignore cubemap projection SEI messages when a frame packing arrangement SEI message with `frame_packing_arrangement_cancel_flag` equal to 0 that applies to the picture is present that is not an effectively applicable frame packing arrangement SEI message.

When a segmented rectangular frame packing arrangement SEI message with `segmented_rect_frame_packing_arrangement_cancel_flag` equal to 0 is present that applies to the picture, a cubemap projection SEI message with `cmp_cancel_flag` equal to 0 shall not be present that applies to the picture. Decoders shall ignore cubemap projection SEI messages when a segmented rectangular frame packing arrangement SEI message with `segmented_rect_frame_packing_arrangement_cancel_flag` equal to 0 is present that applies to the picture.

cmp_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous cubemap projection SEI message in output order. `cmp_cancel_flag` equal to 0 indicates that cubemap projection information follows.

cmp_persistence_flag specifies the persistence of the cubemap projection SEI message for the current layer.

`cmp_persistence_flag` equal to 0 specifies that the cubemap projection SEI message applies to the current decoded picture only.

Let `picA` be the current picture. `cmp_persistence_flag` equal to 1 specifies that the cubemap projection SEI message persists for the current layer in output order until one or more of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture `picB` in the current layer in an access unit containing a cubemap projection SEI message that is applicable to the current layer is output for which `PicOrderCnt(picB)` is greater than `PicOrderCnt(picA)`, where `PicOrderCnt(picB)` and `PicOrderCnt(picA)` are the `PicOrderCntVal` values of `picB` and `picA`, respectively, immediately after the invocation of the decoding process for picture order count for `picB`.

D.3.41.3 Fisheye video information SEI message semantics

The presence of the fisheye video information SEI message for any picture of a CLVS indicates that the picture is a fisheye video picture containing a number of active areas captured by fisheye camera lens. The information carried in the fisheye video information SEI message enables remapping of the colour samples of the pictures onto a sphere coordinate space in sphere coordinates (ϕ , θ), for use in omnidirectional video applications for which the viewing perspective is from the origin looking outward toward the inside of the sphere. The sphere coordinates are defined so that ϕ is the azimuth (longitude, increasing eastward) and θ is the elevation (latitude, increasing northward).

When a fisheye video information SEI message is present for any picture of a CLVS of a particular layer, a fisheye video information SEI message shall be present for the first picture of the CLVS and no equirectangular projection SEI message or cubemap projection SEI message shall be present for any picture of the CLVS.

When `general_non_packed_constraint_flag` is equal to 1 in the active SPS for the current layer, there shall be no fisheye video information SEI messages applicable for any picture of the CLVS of the current layer.

When `aspect_ratio_idc` is present and greater than 1 in the active SPS for the current layer, there should be no fisheye video information SEI messages applicable for any picture of the CLVS of the current layer.

When a frame packing arrangement SEI message with `frame_packing_arrangement_cancel_flag` equal to 0 or a segmented rectangular frame packing arrangement SEI message with `segmented_rect_frame_packing_arrangement_cancel_flag` equal to 0 that applies to the picture is present, a fisheye video information SEI message with `fisheye_cancel_flag` equal to 0 that applies to the picture shall not be present. Decoders shall ignore fisheye video information SEI messages when a frame packing arrangement SEI message with `frame_packing_arrangement_cancel_flag` equal to 0 or a segmented rectangular frame packing arrangement SEI message with `segmented_rect_frame_packing_arrangement_cancel_flag` equal to 0 that applies to the picture is present.

fisheye_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous fisheye video information SEI message in output order. **fisheye_cancel_flag** equal to 0 indicates that fisheye video information follows.

fisheye_persistence_flag specifies the persistence of the fisheye video information SEI message for the current layer.

fisheye_persistence_flag equal to 0 specifies that the fisheye video information SEI message applies to the current decoded picture only.

Let **picA** be the current picture. **fisheye_persistence_flag** equal to 1 specifies that the fisheye video information SEI message persists for the current layer in output order until one or more of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture **picB** in the current layer in an access unit containing a fisheye video information SEI message that is applicable to the current layer is output for which **PicOrderCnt(picB)** is greater than **PicOrderCnt(picA)**, where **PicOrderCnt(picB)** and **PicOrderCnt(picA)** are the **PicOrderCntVal** values of **picB** and **picA**, respectively, immediately after the invocation of the decoding process for picture order count for **picB**.

fisheye_view_dimension_idc indicates the alignment and viewing direction of a fisheye lens, as follows:

- **fisheye_view_dimension_idc** equal to 0 indicates that **fisheye_num_active_areas** is equal to 2, and the values of **fisheye_camera_centre_azimuth**, **fisheye_camera_centre_elevation**, **fisheye_camera_centre_tilt**, **fisheye_camera_centre_offset_x**, **fisheye_camera_centre_offset_y**, and **fisheye_camera_centre_offset_z** are such that the active areas have aligned optical axes and face opposite directions, and the sum of **fisheye_field_of_view** values is greater than or equal to $360 * 2^{16}$.
- **fisheye_view_dimension_idc** equal to 1 indicates that **fisheye_num_active_areas** is equal to 2, and the values of **fisheye_camera_centre_azimuth**, **fisheye_camera_centre_elevation**, **fisheye_camera_centre_tilt**, **fisheye_camera_centre_offset_x**, **fisheye_camera_centre_offset_y**, and **fisheye_camera_centre_offset_z** are such that the active areas have parallel optical axes that are orthogonal to the line intersecting the camera centre points, and the camera corresponding to **i** equal to 0 is the left view.
- **fisheye_view_dimension_idc** equal to 2 indicates that **fisheye_num_active_areas** is equal to 2, and the values of **fisheye_camera_centre_azimuth**, **fisheye_camera_centre_elevation**, **fisheye_camera_centre_tilt**, **fisheye_camera_centre_offset_x**, **fisheye_camera_centre_offset_y**, and **fisheye_camera_centre_offset_z** are such that the active areas have parallel optical axes that are orthogonal to the line intersecting the camera centre points, and the camera corresponding to **i** equal to 0 is the right view.
- **fisheye_view_dimension_idc** equal to 7 indicates that no additional constraints are implied for the syntax element values within the fisheye video information SEI message.
- Values of **fisheye_view_dimension_idc** in the range of 3 to 6, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of **fisheye_view_dimension_idc** in the range of 3 to 6, inclusive, shall ignore it.

fisheye_reserved_zero_3bits shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **fisheye_reserved_zero_3bits** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **fisheye_reserved_zero_3bits**.

fisheye_num_active_areas_minus1 plus 1 specifies the number of active areas in the coded picture. The value of **fisheye_num_active_areas_minus1** shall be in the range of 0 to 3, inclusive. Values of **fisheye_num_active_areas_minus1** greater than 3 are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a fisheye video information SEI message with **fisheye_num_active_areas_minus1** greater than 3 shall ignore the fisheye video information SEI message.

fisheye_circular_region_centre_x[i] and **fisheye_circular_region_centre_y[i]** specify the horizontal and vertical coordinates of the centre of the circular region that contains the **i**-th active area in the coded picture, respectively, in units of 2^{-16} luma samples. The value of **fisheye_circular_region_centre_x[i]** and **fisheye_circular_region_centre_y[i]** shall be in the range of 0 to $65\,536 * 2^{16} - 1$ (i.e., 4 294 967 295), inclusive.

fisheye_rect_region_top[i], **fisheye_rect_region_left[i]**, **fisheye_rect_region_width[i]**, and **fisheye_rect_region_height[i]** specify the coordinates of the top-left corner and the width and height of the **i**-th rectangular region that contains the **i**-th active area, in units of luma samples.

The value of **fisheye_rect_region_top[i]** shall be in the range of **SubHeightC * conf_win_top_offset** to **pic_height_in_luma_samples - (SubHeightC * conf_win_bottom_offset + 1)**, inclusive.

The value of **fisheye_rect_region_left[i]** shall be in the range of **SubWidthC * conf_win_left_offset** to **pic_width_in_luma_samples - (SubWidthC * conf_win_right_offset + 1)**, inclusive.

The value of `fisheye_rect_region_width[i]` shall be in the range of 1 to $\text{pic_width_in_luma_samples} - \text{SubWidthC} * (\text{conf_win_left_offset} + \text{conf_win_right_offset})$, inclusive.

The value of `fisheye_rect_region_height[i]` shall be in the range of 1 to $\text{pic_height_in_luma_samples} - \text{SubHeightC} * (\text{conf_win_top_offset} + \text{conf_win_bottom_offset})$, inclusive.

The sum of `fisheye_rect_region_top[i]` and `fisheye_rect_region_height[i]` shall be less than or equal to $\text{pic_height_in_luma_samples} - \text{SubHeightC} * \text{conf_win_bottom_offset}$.

The sum of `fisheye_rect_region_left[i]` and `fisheye_rect_region_width[i]` shall be less than or equal to $\text{pic_width_in_luma_samples} - \text{SubWidthC} * \text{conf_win_right_offset}$.

`fisheye_circular_region_radius[i]` specifies the radius of the circular region that contains the *i*-th active area that is defined as a length from the centre of the circular region specified by `fisheye_circular_region_centre_x[i]` and `fisheye_circular_region_centre_y[i]` to the outermost pixel boundary of the circular region, in units of 2^{-16} luma samples, that corresponds to the maximum field of view of the *i*-th fisheye lens, specified by `fisheye_field_of_view[i]`. The value of `fisheye_circular_region_radius[i]` shall be in the range of 0 to $65\,536 * 2^{16} - 1$ (i.e., 4 294 967 295), inclusive.

The *i*-th active area is defined as the intersection of the *i*-th rectangular region, specified by `fisheye_rect_region_top[i]`, `fisheye_rect_region_left[i]`, `fisheye_rect_region_width[i]`, and `fisheye_rect_region_height[i]`, and the *i*-th circular region, specified by `fisheye_circular_region_centre_x[i]`, `fisheye_circular_region_centre_y[i]`, and `fisheye_circular_region_radius[i]`.

Each active area shall contain at least one sample location. There shall not be any sample location that is within more than one active area.

`fisheye_scene_radius[i]` specifies the radius of a circular region within the *i*-th active area in units of 2^{-16} luma samples, where the obstruction, such as the camera body, is not included in the region specified by `fisheye_circular_region_centre_x[i]`, `fisheye_circular_region_centre_y[i]`, and `fisheye_scene_radius[i]`. The value of `fisheye_scene_radius[i]` shall be less than or equal to `fisheye_circular_region_radius[i]`, and shall be in the range of 0 to $65\,536 * 2^{16} - 1$ (i.e., 4 294 967 295), inclusive. The enclosed area is the suggested area for stitching as recommended by the encoder.

`fisheye_camera_centre_azimuth[i]` and **`fisheye_camera_centre_elevation[i]`** indicate the sphere coordinates that correspond to the centre of the circular region that contains the *i*-th active area in the cropped output picture, in units of 2^{-16} degrees. The value of `fisheye_camera_centre_azimuth[i]` shall be in the range of $-180 * 2^{16}$ (i.e., -11 796 480) to $180 * 2^{16} - 1$ (i.e., 11 796 479), inclusive, and the value of `fisheye_camera_centre_elevation[i]` shall be in the range of $-90 * 2^{16}$ (i.e., -5 898 240) to $90 * 2^{16}$ (i.e., 5 898 240), inclusive.

`fisheye_camera_centre_tilt[i]` indicates the tilt angle of the sphere region that corresponds to the *i*-th active area of the cropped output picture, in units of 2^{-16} degrees. The value of `fisheye_camera_centre_tilt[i]` shall be in the range of $-180 * 2^{16}$ (i.e., -11 796 480) to $180 * 2^{16} - 1$ (i.e., 11 796 479), inclusive.

`fisheye_camera_centre_offset_x[i]`, **`fisheye_camera_centre_offset_y[i]`** and **`fisheye_camera_centre_offset_z[i]`** indicate the XYZ offset values, in units of 2^{-16} millimeters, of the focal centre of the fisheye camera lens corresponding to the *i*-th active area from the focal centre origin of the overall fisheye camera configuration. The value of each of `fisheye_camera_centre_offset_x[i]`, `fisheye_camera_centre_offset_y[i]`, and `fisheye_camera_centre_offset_z[i]` shall be in the range of 0 to $65\,536 * 2^{16} - 1$ (i.e., 4 294 967 295), inclusive.

`fisheye_field_of_view[i]` specifies the field of view of the lens that corresponds to the *i*-th active area in the coded picture, in units of 2^{-16} degrees. The value of `fisheye_field_of_view[i]` shall be in the range of 0 to $360 * 2^{16}$ (i.e., 23 592 960), inclusive.

`fisheye_num_polynomial_coeffs[i]` specifies the number of polynomial coefficients for the circular region corresponding to the *i*-th active area. The value of `fisheye_num_polynomial_coeffs[i]` shall be in the range of 0 to 8, inclusive. Values of `fisheye_num_polynomial_coeffs[i]` greater than 8 are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a fisheye video information SEI message with `fisheye_num_polynomial_coeffs[i]` greater than 8 shall ignore the fisheye video information SEI message.

`fisheye_polynomial_coeff[i][j]` specifies the *j*-th polynomial coefficient value, in units of 2^{-24} , of the curve function that maps the normalized distance of a luma sample from the centre of the circular region corresponding to the *i*-th active area to the angular value of a sphere coordinate from the normal vector of a nominal imaging plane that passes through the centre of the sphere coordinate system for the *i*-th active region. The value of `fisheye_polynomial_coeff[i][j]` shall be in the range of $-128 * 2^{24}$ (i.e., -2 147 483 648) to $128 * 2^{24} - 1$ (i.e., 2 147 483 647), inclusive.

D.3.41.4 Sphere rotation SEI message semantics

The sphere rotation SEI message provides information on rotation angles yaw (α), pitch (β), and roll (γ) that are used for conversion between the global coordinate axes and the local coordinate axes.

Relative to an (x, y, z) Cartesian coordinate system, yaw expresses a rotation around the z (vertical, up) axis, pitch rotates around the y (lateral, side-to-side) axis, and roll rotates around the x (back-to-front) axis. Rotations are extrinsic, i.e., around x, y, and z fixed reference axes. The angles increase clockwise when looking from the origin towards the positive end of an axis.

sphere_rotation_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous sphere rotation SEI message in output order. sphere_rotation_cancel_flag equal to 0 indicates that sphere rotation information follows.

sphere_rotation_persistence_flag specifies the persistence of the sphere rotation SEI message for the current layer.

sphere_rotation_persistence_flag equal to 0 specifies that the sphere rotation SEI message applies to the current decoded picture only.

Let picA be the current picture. sphere_rotation_persistence_flag equal to 1 specifies that the sphere rotation SEI message persists for the current layer in output order until one or more of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture picB in the current layer in an access unit containing a sphere rotation SEI message that is applicable to the current layer is output for which $\text{PicOrderCnt}(\text{picB})$ is greater than $\text{PicOrderCnt}(\text{picA})$, where $\text{PicOrderCnt}(\text{picB})$ and $\text{PicOrderCnt}(\text{picA})$ are the PicOrderCntVal values of picB and picA, respectively, immediately after the invocation of the decoding process for picture order count for picB.

When an equirectangular projection SEI message with **erp_cancel_flag** equal to 0 or a cubemap projection SEI message with **cmp_cancel_flag** equal to 0 is not present in the CLVS that applies to the current picture and precedes the sphere rotation SEI message in decoding order, a sphere rotation SEI message with **sphere_rotation_cancel_flag** equal to 0 shall not be present in the CLVS that applies to the current picture. Decoders shall ignore sphere rotation SEI messages with **sphere_rotation_cancel_flag** equal to 0 that do not follow, in decoding order, an equirectangular projection SEI message with **erp_cancel_flag** equal to 0 or a cubemap projection SEI message with **cmp_cancel_flag** equal to 0 in the CLVS that applies to the current picture.

sphere_rotation_reserved_zero_6bits shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for sphere_rotation_reserved_zero_6bits are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of sphere_rotation_reserved_zero_6bits.

yaw_rotation specifies the value of the yaw rotation angle, in units of 2^{-16} degrees. The value of yaw_rotation shall be in the range of $-180 * 2^{16}$ (i.e., -11 796 480) to $180 * 2^{16} - 1$ (i.e., 11 796 479), inclusive. When not present, the value of yaw_rotation is inferred to be equal to 0.

pitch_rotation specifies the value of the pitch rotation angle, in units of 2^{-16} degrees. The value of pitch_rotation shall be in the range of $-90 * 2^{16}$ (i.e., -5 898 240) to $90 * 2^{16}$ (i.e., 5 898 240), inclusive. When not present, the value of pitch_rotation is inferred to be equal to 0.

roll_rotation specifies the value of the roll rotation angle, in units of 2^{-16} degrees. The value of roll_rotation shall be in the range of $-180 * 2^{16}$ (i.e., -11 796 480) to $180 * 2^{16} - 1$ (i.e., 11 796 479), inclusive. When not present, the value of roll_rotation is inferred to be equal to 0.

D.3.41.5 Region-wise packing SEI message semantics

The region-wise packing SEI message provides information to enable remapping of the colour samples of the cropped decoded pictures onto projected pictures as well as information on the location and size of the guard bands, if any.

rwp_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous region-wise packing SEI message in output order. rwp_cancel_flag equal to 0 indicates that region-wise packing information follows.

rwp_persistence_flag specifies the persistence of the region-wise packing SEI message for the current layer.

rwp_persistence_flag equal to 0 specifies that the region-wise packing SEI message applies to the current decoded picture only.

Let picA be the current picture. rwp_persistence_flag equal to 1 specifies that the region-wise packing SEI message persists for the current layer in output order until one or more of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture picB in the current layer in an access unit containing a region-wise packing SEI message that is applicable to the current layer is output for which $\text{PicOrderCnt}(\text{picB})$ is greater than $\text{PicOrderCnt}(\text{picA})$, where

PicOrderCnt(picB) and PicOrderCnt(picA) are the PicOrderCntVal values of picB and picA, respectively, immediately after the invocation of the decoding process for picture order count for picB.

When an equirectangular projection SEI message with `erp_cancel_flag` equal to 0 and `erp_guard_band_flag` equal to 0 or a cubemap projection SEI message with `cmp_cancel_flag` equal to 0 is not present in the CLVS that applies to the current picture and precedes the region-wise packing SEI message in decoding order, a region-wise packing SEI message with `rwp_cancel_flag` equal to 0 shall not be present in the CLVS that applies to the current picture. Decoders shall ignore region-wise packing SEI messages with `rwp_cancel_flag` equal to 0 that do not follow, in decoding order, an equirectangular projection SEI message with `erp_cancel_flag` equal to 0 or a cubemap projection SEI message with `cmp_cancel_flag` equal to 0 in the CLVS that applies to the current picture.

For the frame packing arrangement scheme indicated by a frame packing arrangement SEI message that applies to the current picture, if a region-wise packing SEI message with `rwp_cancel_flag` equal to 0 is present that applies to the current picture, the frame packing arrangement scheme applies to the projected picture, otherwise, the frame packing arrangement scheme applies to the cropped decoded picture.

If a frame packing arrangement SEI message with `frame_packing_arrangement_cancel_flag` equal to 0, `frame_packing_arrangement_type` equal to 3, 4, or 5, and `quincunx_sampling_flag` equal to 0 is not present that applies to the current picture, the variables `StereoFlag`, `TopBottomFlag`, `SideBySideFlag`, and `TempInterleavingFlag` are all set equal to 0, the variables `HorDiv1` and `VerDiv1` are both set equal to 1. Otherwise the following applies:

- `StereoFlag` is set equal to 1.
- When the `frame_packing_arrangement_type` is equal to 3, `SideBySideFlag` is set equal to 1, `TopBottomFlag` and `TempInterleavingFlag` are both set equal to 0, `HorDiv1` is set equal to 2 and `VerDiv1` is set equal to 1.
- When the `frame_packing_arrangement_type` is equal to 4, `TopBottomFlag` is set equal to 1, `SideBySideFlag` and `TempInterleavingFlag` are both set equal to 0, `HorDiv1` is set equal to 1 and `VerDiv1` is set equal to 2.
- When the `frame_packing_arrangement_type` is equal to 5, `TempInterleavingFlag` is set equal to 1, `TopBottomFlag` and `SideBySideFlag` are both set equal to 0, `HorDiv1` and `VerDiv1` are both set equal to 1.

constituent_picture_matching_flag equal to 1 specifies that the projected region information, packed region information, and guard band region information in this SEI message apply individually to each constituent picture and that the packed picture and the projected picture have the same stereoscopic frame packing format indicated by the frame packing arrangement SEI message. **constituent_picture_matching_flag** equal to 0 specifies that the projected region information, packed region information, and guard band region information in this SEI message apply to the projected picture.

When either of the following conditions is true, the value of **constituent_picture_matching_flag** shall be equal to 0:

- `StereoFlag` is equal to 0.
- `StereoFlag` is equal to 1 and `frame_packing_arrangement_type` is equal to 5.

rwp_reserved_zero_5bits shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for `rwp_reserved_zero_5bits[i]` are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of `rwp_reserved_zero_5bits[i]`.

num_packed_regions specifies the number of packed regions when **constituent_picture_matching_flag** is equal to 0. The value of **num_packed_regions** shall be greater than 0. When **constituent_picture_matching_flag** is equal to 1, the total number of packed regions is equal to **num_packed_regions** * 2, and the information in each entry of the loop of **num_packed_regions** entries applies to each constituent picture of the projected picture and the packed picture.

proj_picture_width and **proj_picture_height** specify the width and height, respectively, of the projected picture, in relative projected picture sample units.

The values of **proj_picture_width** and **proj_picture_height** shall both be greater than 0.

packed_picture_width and **packed_picture_height** specify the width and height, respectively, of the packed picture, in relative packed picture sample units.

The values of **packed_picture_width** and **packed_picture_height** shall both be greater than 0.

It is a requirement of bitstream conformance that **packed_picture_width** and **packed_picture_height** shall have such values that **packed_picture_width** is an integer multiple of **cropPicWidth** and **packed_picture_height** is an integer multiple of **cropPicHeight**, where **cropPicWidth** and **cropPicHeight** are the width and height, respectively, of the cropped decoded picture.

rwp_reserved_zero_4bits[i] shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for `rwp_reserved_zero_4bits[i]` are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of `rwp_reserved_zero_4bits[i]`.

rwpx_transform_type[i] specifies the rotation and mirroring to be applied to the i-th packed region to remap to the i-th projected region. When **rwpx_transform_type[i]** specifies both rotation and mirroring, rotation applies before mirroring. The values of **rwpx_transform_type[i]** are specified in Table D.22.

Table D.22 – rwpx_transform_type[i] values

Value	Description
0	no transform
1	mirroring horizontally
2	rotation by 180 degrees (anticlockwise)
3	rotation by 180 degrees (anticlockwise) before mirroring horizontally
4	rotation by 90 degrees (anticlockwise) before mirroring horizontally
5	rotation by 90 degrees (anticlockwise)
6	rotation by 270 degrees (anticlockwise) before mirroring horizontally
7	rotation by 270 degrees (anticlockwise)

rwpx_guard_band_flag[i] equal to 0 specifies that the i-th packed region does not have a guard band. **rwpx_guard_band_flag[i]** equal to 1 specifies that the i-th packed region has a guard band.

proj_region_width[i], **proj_region_height[i]**, **proj_region_top[i]** and **proj_region_left[i]** specify the width, height, top sample row, and the left-most sample column, respectively, of the i-th projected region, either within the projected picture (when **constituent_picture_matching_flag** is equal to 0) or within the constituent picture of the projected picture (when **constituent_picture_matching_flag** is equal to 1).

proj_region_width[i], **proj_region_height[i]**, **proj_region_top[i]**, and **proj_region_left[i]** are indicated in relative projected picture sample units.

NOTE 1 – Two projected regions may partially or entirely overlap with each other.

packed_region_width[i], **packed_region_height[i]**, **packed_region_top[i]**, and **packed_region_left[i]** specify the width, height, the top luma sample row, and the left-most luma sample column, respectively, of the packed region, either within the region-wise packed picture (when **constituent_picture_matching_flag** is equal to 0) or within each constituent picture of the region-wise packed picture (when **constituent_picture_matching_flag** is equal to 1).

packed_region_width[i], **packed_region_height[i]**, **packed_region_top[i]**, and **packed_region_left[i]** are indicated in relative region-wise packed picture sample units. **packed_region_width[i]**, **packed_region_height[i]**, **packed_region_top[i]**, and **packed_region_left[i]** shall represent integer horizontal and vertical coordinates of luma sample units within the cropped decoded pictures.

NOTE 2 – Two packed regions may partially or entirely overlap with each other.

rwpx_left_guard_band_width[i] specifies the width of the guard band on the left side of the i-th packed region in relative region-wise packed picture sample units. When **chroma_format_idc** is equal to 1 (4:2:0 chroma format) or 2 (4:2:2 chroma format), **rwpx_left_guard_band_width[i]** shall correspond to an even number of luma samples within the cropped decoded picture.

rwpx_right_guard_band_width[i] specifies the width of the guard band on the right side of the i-th packed region in relative region-wise packed picture sample units. When **chroma_format_idc** is equal to 1 (4:2:0 chroma format) or 2 (4:2:2 chroma format), **rwpx_right_guard_band_width[i]** shall correspond to an even number of luma samples within the cropped decoded picture.

rwpx_top_guard_band_height[i] specifies the height of the guard band above the i-th packed region in relative region-wise packed picture sample units. When **chroma_format_idc** is equal to 1 (4:2:0 chroma format), **rwpx_top_guard_band_height[i]** shall correspond to an even number of luma samples within the cropped decoded picture.

rwpx_bottom_guard_band_height[i] specifies the height of the guard band below the i-th packed region in relative region-wise packed picture sample units. When **chroma_format_idc** is equal to 1 (4:2:0 chroma format), **rwpx_bottom_guard_band_height[i]** shall correspond to an even number of luma samples within the cropped decoded picture.

When **rwpx_guard_band_flag[i]** is equal to 1, **rwpx_left_guard_band_width[i]**, **rwpx_right_guard_band_width[i]**, **rwpx_top_guard_band_height[i]**, or **rwpx_bottom_guard_band_height[i]** shall be greater than 0.

The i-th packed region as specified by this SEI message shall not overlap with any other packed region specified by the same SEI message or any guard band specified by the same SEI message.

The guard bands associated with the i -th packed region, if any, as specified by this SEI message shall not overlap with any packed region specified by the same SEI message or any other guard bands specified by the same SEI message.

rwg_guard_band_not_used_for_pred_flag[i] equal to 0 specifies that the guard bands may or may not be used in the inter prediction process. **rwg_guard_band_not_used_for_pred_flag[i]** equal to 1 specifies that the sample values of the guard bands are not used in the inter prediction process.

NOTE 3 – When **rwg_guard_band_not_used_for_pred_flag[i]** is equal to 1, the sample values within guard bands in cropped decoded pictures can be rewritten even if the cropped decoded pictures were used as references for inter prediction of subsequent pictures to be decoded. For example, the content of a packed region can be seamlessly expanded to its guard band with decoded and re-projected samples of another packed region.

rwg_guard_band_type[i][j] indicates the type of the guard bands for the i -th packed region as follows, with j equal to 0, 1, 2, or 3 indicating that the semantics below apply to the left, right, top, or bottom edge, respectively, of the packed region:

- **rwg_guard_band_type[i][j]** equal to 0 indicates that the content of the guard bands in relation to the content of the packed regions is unspecified. When **rwg_guard_band_not_used_for_pred_flag[i]** is equal to 0, **rwg_guard_band_type[i][j]** shall not be equal to 0.
- **rwg_guard_band_type[i][j]** equal to 1 indicates that the content of the guard bands suffices for interpolation of sample values at sub-pel sample fractional locations within the packed region and less than one sample outside of the boundary of the packed region.

NOTE 4 – **rwg_guard_band_type[i][j]** equal to 1 can be used when the boundary samples of a packed region have been copied horizontally or vertically to the guard band.

- **rwg_guard_band_type[i][j]** equal to 2 indicates that the content of the guard bands represents actual picture content that is spherically adjacent to the content in the packed region and is on the surface of the packed region at quality that gradually changes from the picture quality of the packed region to that of the spherically adjacent packed region.
- **rwg_guard_band_type[i][j]** equal to 3 indicates that the content of the guard bands represents actual picture content that is spherically adjacent to the content in the packed region and is on the surface of the packed region at a similar picture quality as within the packed region.
- **rwg_guard_band_type[i][j]** values greater than 3 are reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value of **rwg_guard_band_type[i][j]** when the value is greater than 3 as equivalent to the value 0.

rwg_guard_band_reserved_zero_3bits[i] shall be equal to 0 in bitstreams conforming to this version of this Specification. Other values for **rwg_guard_band_reserved_zero_3bits[i]** are reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore the value of **rwg_guard_band_reserved_zero_3bits[i]**.

The variables **NumPackedRegions**, **PackedRegionLeft[n]**, **PackedRegionTop[n]**, **PackedRegionWidth[n]**, **PackedRegionHeight[n]**, **ProjRegionLeft[n]**, **ProjRegionTop[n]**, **ProjRegionWidth[n]**, **ProjRegionHeight[n]**, and **TransformType[n]** are derived as follows:

- For n in the range of 0 to **num_packed_regions** – 1, inclusive, the following applies:
 - **PackedRegionLeft[n]** is set equal to **packed_region_left[n]**.
 - **PackedRegionTop[n]** is set equal to **packed_region_top[n]**.
 - **PackedRegionWidth[n]** is set equal to **packed_region_width[n]**.
 - **PackedRegionHeight[n]** is set equal to **packed_region_height[n]**.
 - **ProjRegionLeft[n]** is set equal to **proj_region_left[n]**.
 - **ProjRegionTop[n]** is set equal to **proj_region_top[n]**.
 - **ProjRegionWidth[n]** is set equal to **proj_region_width[n]**.
 - **ProjRegionHeight[n]** is set equal to **proj_region_height[n]**.
 - **TransformType[n]** is set equal to **rwg_transform_type[n]**.
- If **constituent_picture_matching_flag** is equal to 0, the following applies:
 - **NumPackedRegions** is set equal to **num_packed_regions**.
- Otherwise (**constituent_picture_matching_flag** is equal to 1), the following applies:
 - **NumPackedRegions** is set equal to $2 * \text{num_packed_regions}$.

- When TopBottomFlag is equal to 1, the following applies:
 - projLeftOffset and packedLeftOffset are both set equal to 0.
 - projTopOffset is set equal to $\text{proj_picture_height} / 2$ and packedTopOffset is set equal to $\text{packed_picture_height} / 2$.
- When SideBySideFlag is equal to 1, the following applies:
 - projLeftOffset is set equal to $\text{proj_picture_width} / 2$ and packedLeftOffset is set equal to $\text{packed_picture_width} / 2$.
 - projTopOffset and packedTopOffset are both set equal to 0.
- For n in the range of $\text{NumPackedRegions} / 2$ to $\text{NumPackedRegions} - 1$, inclusive, the following applies:
 - $n\text{Idx}$ is set equal to $n - \text{NumPackedRegions} / 2$.
 - $\text{PackedRegionLeft}[n]$ is set equal to $\text{packed_region_left}[n\text{Idx}] + \text{packedLeftOffset}$.
 - $\text{PackedRegionTop}[n]$ is set equal to $\text{packed_region_top}[n\text{Idx}] + \text{packedTopOffset}$.
 - $\text{PackedRegionWidth}[n]$ is set equal to $\text{packed_region_width}[n\text{Idx}]$.
 - $\text{PackedRegionHeight}[n]$ is set equal to $\text{packed_region_height}[n\text{Idx}]$.
 - $\text{ProjRegionLeft}[n]$ is set equal to $\text{proj_region_left}[n\text{Idx}] + \text{projLeftOffset}$.
 - $\text{ProjRegionTop}[n]$ is set equal to $\text{proj_region_top}[n\text{Idx}] + \text{projTopOffset}$.
 - $\text{ProjRegionWidth}[n]$ is set equal to $\text{proj_region_width}[n\text{Idx}]$.
 - $\text{ProjRegionHeight}[n]$ is set equal to $\text{proj_region_height}[n\text{Idx}]$.
 - $\text{TransformType}[n]$ is set equal to $\text{rwp_transform_type}[n\text{Idx}]$.

For each value of n in the range of 0 to $\text{NumPackedRegions} - 1$, inclusive, the values of $\text{ProjRegionWidth}[n]$, $\text{ProjRegionHeight}[n]$, $\text{ProjRegionTop}[n]$, and $\text{ProjRegionLeft}[n]$ are constrained as follows:

- $\text{ProjRegionWidth}[n]$ shall be in the range of 1 to $\text{proj_picture_width}$, inclusive.
- $\text{ProjRegionHeight}[n]$ shall be in the range of 1 to $\text{proj_picture_height}$, inclusive.
- $\text{ProjRegionLeft}[n]$ shall be in the range of 0 to $\text{proj_picture_width} - 1$, inclusive.
- $\text{ProjRegionTop}[n]$ shall be in the range of 0 to $\text{proj_picture_height} - 1$, inclusive.
- If $\text{ProjRegionTop}[n]$ is less than $\text{proj_picture_height} / \text{VerDiv1}$, the sum of $\text{ProjRegionTop}[n]$ and $\text{ProjRegionHeight}[n]$ shall be less than or equal to $\text{proj_picture_height} / \text{VerDiv1}$. Otherwise, the sum of $\text{ProjRegionTop}[n]$ and $\text{ProjRegionHeight}[n]$ shall be less than or equal to $\text{proj_picture_height} / \text{VerDiv1} * 2$.

For each value of n in the range of 0 to $\text{NumPackedRegions} - 1$, inclusive, the values of $\text{PackedRegionWidth}[n]$, $\text{PackedRegionHeight}[n]$, $\text{PackedRegionTop}[n]$, and $\text{PackedRegionLeft}[n]$ are constrained as follows:

- $\text{PackedRegionWidth}[n]$ shall be in the range of 1 to $\text{packed_picture_width}$, inclusive.
- $\text{PackedRegionHeight}[n]$ shall be in the range of 1 to $\text{packed_picture_height}$, inclusive.
- $\text{PackedRegionLeft}[n]$ shall be in the range of 0 to $\text{packed_picture_width} - 1$, inclusive.
- $\text{PackedRegionTop}[n]$ shall be in the range of 0 to $\text{packed_picture_height} - 1$, inclusive.
- If $\text{PackedRegionLeft}[n]$ is less than $\text{packed_picture_width} / \text{HorDiv1}$, the sum of $\text{PackedRegionLeft}[n]$ and $\text{PackedRegionWidth}[n]$ shall be less than or equal to $\text{packed_picture_width} / \text{HorDiv1}$. Otherwise, the sum of $\text{PackedRegionLeft}[n]$ and $\text{PackedRegionWidth}[n]$ shall be less than or equal to $\text{packed_picture_width} / \text{HorDiv1} * 2$.
- If $\text{PackedRegionTop}[n]$ is less than $\text{packed_picture_height} / \text{VerDiv1}$, the sum of $\text{PackedRegionTop}[n]$ and $\text{PackedRegionHeight}[n]$ shall be less than or equal to $\text{packed_picture_height} / \text{VerDiv1}$. Otherwise, the sum of $\text{PackedRegionTop}[n]$ and $\text{PackedRegionHeight}[n]$ shall be less than or equal to $\text{packed_picture_height} / \text{VerDiv1} * 2$.
- When chroma_format_idc is equal to 1 (4:2:0 chroma format) or 2 (4:2:2 chroma format), $\text{PackedRegionLeft}[n]$ shall correspond to an even horizontal coordinate value of luma sample units, and $\text{PackedRegionWidth}[n]$ shall correspond to an even number of luma samples, both within the decoded picture.
- When chroma_format_idc is equal to 1 (4:2:0 chroma format), $\text{PackedRegionTop}[n]$ shall correspond to an even vertical coordinate value of luma sample units, and $\text{ProjRegionHeight}[n]$ shall correspond to an even number of luma samples, both within the decoded picture.

D.3.41.6 Omnidirectional viewport SEI message semantics

The omnidirectional viewport SEI message specifies the coordinates of one or more regions of sphere-coordinate geometry, bounded by four great circles, corresponding to viewports recommended for display when the user does not have control of the viewing orientation or has released control of the viewing orientation.

When an effectively applicable frame packing arrangement SEI message, as specified in clause D.3.41.1 or D.3.41.2, that applies to the picture is present, the information indicated by the omnidirectional viewport SEI message applies to both views.

omni_viewport_id contains an identifying number that may be used to identify the purpose of the one or more recommended viewport regions.

omni_viewport_id equal to 0 indicates that the recommended viewports are per "director's cut", i.e., a viewport suggested according to the creative intent of the content author or content provider. omni_viewport_id equal to 1 indicates that the recommended viewports are selected based on measurements of viewing statistics.

Values of omni_viewport_id from 2 to 511, inclusive, may be used as determined by the application. Values of omni_viewport_id from 512 to 1 023 are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of omni_viewport_id in the range of 512 to 1 023, inclusive, shall ignore it.

omni_viewport_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous omnidirectional viewport SEI message in output order. omni_viewport_cancel_flag equal to 0 indicates that omnidirectional viewport information follows.

omni_viewport_persistence_flag specifies the persistence of the omnidirectional viewport SEI message for the current layer.

omni_viewport_persistence_flag equal to 0 specifies that the omnidirectional viewport SEI message applies to the current decoded picture only.

Let picA be the current picture. omni_viewport_persistence_flag equal to 1 specifies that the omnidirectional viewport SEI message persists for the current layer in output order until one or more of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture picB in the current layer in an access unit containing an omnidirectional viewport SEI message that is applicable to the current layer is output for which PicOrderCnt(picB) is greater than PicOrderCnt(picA), where PicOrderCnt(picB) and PicOrderCnt(picA) are the PicOrderCntVal values of picB and picA, respectively, immediately after the invocation of the decoding process for picture order count for picB.

When an equirectangular projection SEI message with erp_cancel_flag equal to 0 or a cubemap projection SEI message with cmp_cancel_flag equal to 0 is not present in the CLVS that applies to the current picture and precedes the omnidirectional viewport SEI message in decoding order, an omnidirectional viewport SEI message with omni_viewport_cancel_flag equal to 0 shall not be present in the CLVS that applies to the current picture. Decoders shall ignore omnidirectional viewport SEI messages with omni_viewport_cancel_flag equal to 0 that do not follow, in decoding order, an equirectangular projection SEI message with erp_cancel_flag equal to 0 or a cubemap projection SEI message with cmp_cancel_flag equal to 0 in the CLVS that applies to the current picture.

omni_viewport_cnt_minus1 plus 1 specifies the number of recommended viewport regions that are indicated by the SEI message.

When omni_viewport_cnt_minus1 is greater than 0 and there is no information provided by external means not specified in this Specification on which recommended viewport is suggested to be displayed, the following applies:

- When omni_viewport_id is equal to 0 or 1, the 0-th recommended viewport is suggested to be displayed when the user does not have control of the viewing orientation or has released control of the viewing orientation.
- When omni_viewport_id is equal to 0, between any two recommended viewports per director's cut, the i-th recommended viewport has higher priority than the j-th recommended viewport for any values of i and j when i is less than j. The 0-th recommended viewport per director's cut has the highest priority.
- When omni_viewport_id is equal to 1, between any two recommended viewports, the i-th recommended viewport has higher popularity, among some selection of candidate viewports, than the j-th recommended viewport for any values of i and j when i is less than j. The 0-th most-viewed recommended viewport has the highest popularity. The selection of the candidate viewports is outside the scope of this Specification.

omni_viewport_azimuth_centre[i] and **omni_viewport_elevation_centre[i]** indicate the centre of the i-th recommended viewport region, in units of 2^{-16} degrees relative to the global coordinate axes. The value of

`omni_viewport_azimuth_centre[i]` shall be in the range of $-180 * 2^{16}$ (i.e., -11 796 480) to $180 * 2^{16} - 1$ (i.e., 11 796 479), inclusive. The value of `omni_viewport_elevation_centre[i]` shall be in the range of $-90 * 2^{16}$ (i.e., -5 898 240) to $90 * 2^{16}$ (i.e., 5 898 240), inclusive.

`omni_viewport_tilt_centre[i]` indicates the tilt angle of the *i*-th recommended viewport region, in units of 2^{-16} degrees. The value of `omni_viewport_tilt_centre[i]` shall be in the range of $-180 * 2^{16}$ (i.e., -11 796 480) to $2^{16} - 1$ (i.e., 11 796 479), inclusive.

`omni_viewport_hor_range[i]` indicates the azimuth range of the *i*-th recommended viewport region, in units of 2^{-16} degrees. The value of `omni_viewport_hor_range[i]` shall be in the range of 1 to $360 * 2^{16}$ (i.e., 23 592 960), inclusive.

`omni_viewport_ver_range[i]` indicates the elevation range of the *i*-th recommended viewport region, in units of 2^{-16} degrees. The value of `omni_viewport_ver_range[i]` shall be in the range of 1 to $180 * 2^{16}$ (i.e., 11 796 480), inclusive.

D.3.41.7 Sample location remapping process

D.3.41.7.1 General

To remap colour sample locations of a region-wise packed picture to a unit sphere, the following ordered steps are applied:

1. A region-wise packed picture is obtained as the cropped decoded picture by decoding a coded picture. For purposes of interpretation of chroma samples, the input to the indicated remapping process is the set of decoded sample values after applying an (unspecified) upsampling conversion process to the 4:4:4 colour sampling format as necessary when `chroma_format_idc` is equal to 1 (4:2:0 chroma format) or 2 (4:2:2 chroma format). This (unspecified) upsampling process should account for the relative positioning relationship between the luma and chroma samples as indicated by `chroma_sample_loc_type_top_field` and `chroma_sample_loc_type_bottom_field`, when present.
2. If region-wise packing is indicated, the sample locations of the region-wise packed picture are converted to sample locations of the respective projected picture as specified in clause D.3.41.7.4. Otherwise, the projected picture is identical to the region-wise packed picture.
3. If frame packing is indicated, the sample locations of the projected picture are converted to sample locations of the respective constituent picture of the projected picture, as specified in clause D.3.41.7.5. Otherwise, the constituent picture of the projected picture is identical to the projected picture.
4. The sample locations of a constituent picture of the projected picture are converted to sphere coordinates relative to the local coordinate axes, as specified in clause D.3.41.7.2.
5. If rotation is indicated, the sphere coordinates relative to the local coordinate axes are converted to sphere coordinates relative to the global coordinate axes, as specified in clause D.3.41.7.3. Otherwise, the global coordinate axes are identical to the local coordinate axes.

The overall process for mapping of luma sample locations within a region-wise packed picture to sphere coordinates relative to the global coordinate axes is normatively specified in clause D.3.41.7.5.

For each region-wise packed picture corresponding to a decoded picture, the following applies:

- When an equirectangular projection SEI message with `erp_cancel_flag` equal to 0 that applies to the picture is present, `ErpFlag` is set equal to 1, and `CmpFlag` is set equal to 0.
- When a cubemap projection SEI message with `cmp_cancel_flag` equal to 0 that applies to the picture is present, `CmpFlag` is set equal to 1, and `ErpFlag` is set equal to 0.
- If a sphere rotation SEI message with `sphere_rotation_cancel_flag` equal to 0 that applies to the picture is present, `RotationFlag` is set equal to 1, and `RotationYaw`, `RotationPitch`, and `RotationRoll` are set equal to `yaw_rotation` $\div 2^{16}$, `pitch_rotation` $\div 2^{16}$, and `roll_rotation` $\div 2^{16}$, respectively.
- Otherwise, `RotationFlag` is set equal to 0.
- If a frame packing arrangement SEI message with `frame_packing_arrangement_cancel_flag` equal to 0 that applies to the picture is not present, `StereoFlag`, `TopBottomFlag`, and `SideBySideFlag` are all set equal to 0, `HorDiv1` is set equal to 1, and `VerDiv1` is set equal to 1.
- Otherwise, the following applies:
 - `StereoFlag` is set equal to 1.
 - If the value of `frame_packing_arrangement_type` of the frame packing arrangement SEI message is equal to 3, `TopBottomFlag` is set equal to 0, `SideBySideFlag` is set equal to 1, `HorDiv1` is set equal to 2 and `VerDiv1` is set equal to 1.

- Otherwise, if the value of `frame_packing_arrangement_type` of the frame packing arrangement SEI message is equal to 4, `TopBottomFlag` is set equal to 1, `SideBySideFlag` is set equal to 0, `HorDiv1` is set equal to 1, and `VerDiv1` is set equal to 2.
- Otherwise, `TopBottomFlag` is set equal to 0, `SideBySideFlag` is set equal to 0, `HorDiv1` is set equal to 1, and `VerDiv1` is set equal to 1.
- If a region-wise packing SEI message with `rwpcancel_flag` equal to 0 that applies to the picture is not present, `RegionWisePackingFlag` is set equal to 0, and `ConstituentPicWidth` and `ConstituentPicHeight` are set to be equal to `cropPicWidth / HorDiv1` and `cropPicHeight / VerDiv1`, respectively, where `cropPicWidth` and `cropPicHeight` are the width and height, respectively, of the cropped decoded picture.
- Otherwise, `RegionWisePackingFlag` is set equal to 1, and `ConstituentPicWidth` and `ConstituentPicHeight` are set equal to `proj_picture_width / HorDiv1` and `proj_picture_height / VerDiv1`, respectively.

To remap colour sample locations of a fisheye video picture to a unit sphere, the sample locations in each of the active regions is converted to locations on the unit sphere as specified in clause D.3.41.7.7.

D.3.41.7.2 Projection for one sample location

Inputs to this process are:

- `pictureWidth` and `pictureHeight`, which are the width and height, respectively, of a monoscopic projected luma picture, in relative projected picture sample units, and
- the centre point of a sample location (`hPos`, `vPos`) along the horizontal and vertical axes, respectively, in relative projected picture sample units, where `hPos` and `vPos` may have non-integer real values.

Outputs of this process are:

- sphere coordinates (ϕ , θ) for the sample location in degrees relative to the local coordinate axes.

The projection for a sample location is derived as follows:

- If `ErpFlag` is equal to 1, the following applies:

- If `RegionWisePackingFlag` is equal to 0 and `erp_guard_band_flag` is equal to 1, the following applies:

$$\begin{aligned} hPos' &= hPos - \text{erp_left_guard_band_width} \\ \text{pictureWidth} &= \text{pictureWidth} - \text{erp_left_guard_band_width} - \text{erp_right_guard_band_width} \end{aligned} \quad (\text{D-54})$$

- Otherwise, the following applies:

$$hPos' = hPos \quad (\text{D-55})$$

- The following applies:

$$\begin{aligned} \phi &= 180 - hPos' * (360 \div \text{pictureWidth}) \\ \theta &= 90 - vPos * (180 \div \text{pictureHeight}) \end{aligned} \quad (\text{D-56})$$

- Otherwise (`CmpFlag` is equal to 1), it is a requirement of bitstream conformance that `pictureWidth` shall be a multiple of 3 and `pictureHeight` shall be a multiple of 2, and that `pictureWidth / 3` shall be equal to `pictureHeight / 2`, and the following applies:

```
lw = pictureWidth / 3
lh = pictureHeight / 2
w = Floor( hPos ÷ lw )
h = Floor( vPos ÷ lh )
tmpHorVal = hPos - w * lw
tmpVerVal = vPos - h * lh
hPos' = -( 2 * tmpHorVal ÷ lw ) + 1
vPos' = -( 2 * tmpVerVal ÷ lh ) + 1
if( w == 1 && h == 0 ) { /* positive x front face */
    x = 1.0
    y = hPos'
    z = vPos'
} else if( w == 1 && h == 1 ) { /* negative x back face */
    x = -1.0
```

$$\begin{aligned}
& y = -vPos' \\
& z = -hPos' \\
& \} \text{ else if(} w == 2 \ \&\& \ h == 1) \{ \text{ /* positive z top face */} \\
& \quad x = -hPos' \\
& \quad y = -vPos' \\
& \quad z = 1.0 \\
& \} \text{ else if(} w == 0 \ \&\& \ h == 1) \{ \text{ /* negative z bottom face */} \\
& \quad x = hPos' \\
& \quad y = -vPos' \\
& \quad z = -1.0 \\
& \} \text{ else if(} w == 0 \ \&\& \ h == 0) \{ \text{ /* positive y left face */} \\
& \quad x = -hPos' \\
& \quad y = 1.0 \\
& \quad z = vPos' \\
& \} \text{ else } \{ \text{ /* (} w == 2 \ \&\& \ h == 0), \text{ /* negative y right face */} \\
& \quad x = hPos' \\
& \quad y = -1.0 \\
& \quad z = vPos' \\
& \} \\
& \phi = \text{Atan2}(y, x) * 180 \div \pi \\
& \theta = \text{Asin}(z \div \text{Sqrt}(x^2 + y^2 + z^2)) * 180 \div \pi
\end{aligned} \tag{D-57}$$

D.3.41.7.3 Conversion from the local coordinate axes to the global coordinate axes

Inputs to this process are:

- rotation_yaw (α_d), rotation_pitch (β_d), rotation_roll (γ_d), all in units of degrees, and
- sphere coordinates (ϕ_d, θ_d) relative to the local coordinate axes.

Outputs of this process are:

- sphere coordinates (ϕ', θ') relative to the global coordinate axes.

The outputs are derived as follows:

$$\begin{aligned}
\phi &= \phi_d * \pi \div 180 \\
\theta &= \theta_d * \pi \div 180 \\
\alpha &= \alpha_d * \pi \div 180 \\
\beta &= \beta_d * \pi \div 180 \\
\gamma &= \gamma_d * \pi \div 180 \\
x_1 &= \text{Cos}(\phi) * \text{Cos}(\theta) \\
y_1 &= \text{Sin}(\phi) * \text{Cos}(\theta) \\
z_1 &= \text{Sin}(\theta) \\
x_2 &= \text{Cos}(\beta) * \text{Cos}(\alpha) * x_1 - \text{Cos}(\beta) * \text{Sin}(\alpha) * y_1 + \text{Sin}(\beta) * z_1 \\
y_2 &= (\text{Cos}(\gamma) * \text{Sin}(\alpha) + \text{Sin}(\gamma) * \text{Sin}(\beta) * \text{Cos}(\alpha)) * x_1 + \\
&\quad (\text{Cos}(\gamma) * \text{Cos}(\alpha) - \text{Sin}(\gamma) * \text{Sin}(\beta) * \text{Sin}(\alpha)) * y_1 - \\
&\quad \text{Sin}(\gamma) * \text{Cos}(\beta) * z_1 \\
z_2 &= (\text{Sin}(\gamma) * \text{Sin}(\alpha) - \text{Cos}(\gamma) * \text{Sin}(\beta) * \text{Cos}(\alpha)) * x_1 + \\
&\quad (\text{Sin}(\gamma) * \text{Cos}(\alpha) + \text{Cos}(\gamma) * \text{Sin}(\beta) * \text{Sin}(\alpha)) * y_1 + \\
&\quad \text{Cos}(\gamma) * \text{Cos}(\beta) * z_1 \\
\phi' &= \text{Atan2}(y_2, x_2) * 180 \div \pi \\
\theta' &= \text{Asin}(z_2) * 180 \div \pi
\end{aligned} \tag{D-58}$$

D.3.41.7.4 Conversion of sample locations for rectangular region-wise packing

Inputs to this process are:

- sample location (x, y) within the packed region, where x and y are in relative packed picture sample units, while the sample location is at an integer sample location within the packed picture,
- the width and the height (projRegWidth, projRegHeight) of the projected region, in relative projected picture sample units,

- the width and the height (packedRegWidth, packedRegHeight) of the packed region, in relative packed picture sample units,
- transform type (transformType), and
- offset values for the sampling position (offsetX, offsetY) in the range of 0, inclusive, to 1, exclusive, in horizontal and vertical relative packed picture sample units, respectively.

NOTE – offsetX and offsetY both equal to 0.5 indicate a sampling position that is in the centre point of a sample in packed picture sample units.

Outputs of this process are:

- the centre point of the sample location (hPos, vPos) within the projected region in relative projected picture sample units, where hPos and vPos may have non-integer real values.

The outputs are derived as follows:

```

if( transformType == 0 || transformType == 1 || transformType == 2 || transformType ==
  3 ) {
    horRatio = projRegWidth ÷ packedRegWidth
    verRatio = projRegHeight ÷ packedRegHeight
} else if( transformType == 4 || transformType == 5 || transformType == 6 ||
  transformType == 7 ) {
    horRatio = projRegWidth ÷ packedRegHeight
    verRatio = projRegHeight ÷ packedRegWidth
}
if( transformType == 0 ) {
    hPos = horRatio * ( x + offsetX )
    vPos = verRatio * ( y + offsetY )
} else if( transformType == 1 ) {
    hPos = horRatio * ( packedRegWidth - x - offsetX )
    vPos = verRatio * ( y + offsetY )
} else if( transformType == 2 ) {
    hPos = horRatio * ( packedRegWidth - x - offsetX )
    vPos = verRatio * ( packedRegHeight - y - offsetY )
} else if( transformType == 3 ) {
    hPos = horRatio * ( x + offsetX )
    vPos = verRatio * ( packedRegHeight - y - offsetY )
} else if( transformType == 4 ) {
    hPos = horRatio * ( y + offsetY )
    vPos = verRatio * ( x + offsetX )
} else if( transformType == 5 ) {
    hPos = horRatio * ( y + offsetY )
    vPos = verRatio * ( packedRegWidth - x - offsetX )
} else if( transformType == 6 ) {
    hPos = horRatio * ( packedRegHeight - y - offsetY )
    vPos = verRatio * ( packedRegWidth - x - offsetX )
} else if( transformType == 7 ) {
    hPos = horRatio * ( packedRegHeight - y - offsetY )
    vPos = verRatio * ( x + offsetX )
}

```

(D-59)

D.3.41.7.5 Mapping of luma sample locations within a cropped decoded picture to sphere coordinates relative to the global coordinate axes

This clause specifies the mapping of luma sample locations within a cropped decoded picture to sphere coordinates relative to the global coordinate axes.

offsetX is set equal to 0.5 and offsetY is set equal to 0.5.

If RegionWisePackingFlag is equal to 1, the following applies for each packed region n in the range of 0 to NumPackedRegions – 1, inclusive:

- For each sample location (xPackedPicture, yPackedPicture) belonging to the n-th packed region, the following applies:
 - The corresponding sample location (xProjPicture, yProjPicture) of the projected picture is derived as follows:
 - x is set equal to $x_{\text{PackedPicture}} - \text{PackedRegionLeft}[n]$.
 - y is set equal to $y_{\text{PackedPicture}} - \text{PackedRegionTop}[n]$.
 - Clause D.3.41.7.4 is invoked with x, y, PackedRegionWidth[n], PackedRegionHeight[n], ProjRegionWidth[n], ProjRegionHeight[n], TransformType[n], offsetX and offsetY as inputs, and the output is assigned to sample location (hPos, vPos).
 - xProjPicture is set equal to $\text{ProjRegionLeft}[n] + h\text{Pos}$.
 - When StereoFlag is equal to 0 or TopBottomFlag is equal to 1, and when xProjPicture is greater than or equal to proj_picture_width, xProjPicture is set equal to $x_{\text{ProjPicture}} - \text{proj_picture_width}$.
 - When SideBySideFlag is equal to 1, the following applies:
 - When $\text{ProjRegionLeft}[n]$ is less than $\text{proj_picture_width} / 2$ and xProjPicture is greater than or equal to $\text{proj_picture_width} / 2$, xProjPicture is set equal to $x_{\text{ProjPicture}} - \text{proj_picture_width} / 2$.
 - When $\text{ProjRegionLeft}[n]$ is greater than or equal to $\text{proj_picture_width} / 2$ and xProjPicture is greater than or equal to $\text{proj_picture_width}$, xProjPicture is set equal to $x_{\text{ProjPicture}} - \text{proj_picture_width} / 2$.
 - yProjPicture is set equal to $\text{ProjRegionTop}[n] + v\text{Pos}$.
 - Clause D.3.41.7.6 is invoked with xProjPicture, yProjPicture, ConstituentPicWidth, and ConstituentPicHeight as inputs, and the outputs indicating the sphere coordinates and the constituent picture index (for frame-packed stereoscopic video) for the luma sample location (xPackedPicture, yPackedPicture) belonging to the n-th packed region in the decoded picture.

Otherwise (RegionWisePackingFlag is equal 0), the following applies for each sample location (x, y) that is not an equirectangular projection guard band sample within the cropped decoded picture, where a sample location (x, y) is an equirectangular projection guard band sample when and only when ErpFlag is equal to 1, x is in the range of 0 to $\text{erp_left_guard_band_width} - 1$, inclusive, or $\text{ConstituentPicWidth} - \text{erp_right_guard_band_width}$ to $\text{ConstituentPicWidth} - 1$, inclusive, and y is in the range of 0 to $\text{ConstituentPicHeight} - 1$, inclusive:

- xProjPicture is set equal to $x + \text{offsetX}$.
- yProjPicture is set equal to $y + \text{offsetY}$.
- If ErpFlag is equal to 0, projPicWidth is set equal to ConstituentPicWidth. Otherwise (ErpFlag is equal to 1), projPicWidth is set equal to $\text{ConstituentPicWidth} - (\text{erp_left_guard_band_width} + \text{erp_right_guard_band_width})$.
- Clause D.3.41.7.6 is invoked with xProjPicture, yProjPicture, projPicWidth, and ConstituentPicHeight as inputs, and the outputs indicating the sphere coordinates and the constituent picture index (for frame-packed stereoscopic video) for the sample location (x, y) within the region-wise packed picture.

D.3.41.7.6 Conversion from a sample location in a projected picture to sphere coordinates relative to the global coordinate axes

Inputs to this process are:

- the centre point of a sample location (xProjPicture, yProjPicture) within a projected picture, where xProjPicture and yProjPicture are in relative projected picture sample units and may have non-integer real values, and
- pictureWidth and pictureHeight, which are the width and height, respectively, of a monoscopic projected luma picture, in relative projected picture sample units.

Outputs of this process are:

- sphere coordinates (azimuthGlobal, elevationGlobal), in units of degrees relative to the global coordinate axes, and
- when StereoFlag is equal to 1, the index of the constituent picture (constituentPicture) equal to 0 or 1.

The outputs are derived with the following ordered steps:

1. constituentPicture, xProjPicture, and yProjPicture are conditionally set as follows:
 - If xProjPicture is greater than or equal to pictureWidth or yProjPicture is greater than or equal to pictureHeight, the following applies:

- constituentPicture is set equal to 1.
 - When xProjPicture is greater than or equal to pictureWidth, xProjPicture is set to xProjPicture – pictureWidth.
 - When yProjPicture is greater than or equal to pictureHeight, yProjPicture is set to yProjPicture – pictureHeight.
 - Otherwise, constituentPicture is set equal to 0.
2. Clause D.3.41.7.2 is invoked with pictureWidth, pictureHeight, xProjPicture, and yProjPicture as inputs, and the output is assigned to azimuthLocal, elevationLocal.
3. azimuthGlobal and elevationGlobal are set as follows:
- If RotationFlag is equal to 1, clause D.3.41.7.3 is invoked with azimuthLocal, elevationLocal, RotationYaw, RotationPitch, and RotationRoll as inputs, and the output is assigned to azimuthGlobal and elevationGlobal.
 - Otherwise, azimuthGlobal is set equal to azimuthLocal and elevationGlobal is set equal to elevationLocal.

D.3.41.7.7 Conversion from a sample location of an active area to sphere coordinates relative to the global coordinate axes

Inputs to this process are:

- the sample location (x, y) in units of luma samples,
- the centre location (x_c, y_c) and the radius (r_c) of the circular region that contains the i-th active area, given by fisheye_circular_region_centre_x[i], fisheye_circular_region_centre_y[i], and fisheye_circular_region_radius[i], respectively, all in units of 2⁻¹⁶ luma samples,
- the field of view (θ_v) of the lens corresponding to the i-th active area, given by fisheye_field_of_view[i], in units of 2⁻¹⁶ degrees,
- the rotation parameters (α_c, β_c, γ_c), given by fisheye_camera_centre_azimuth[i], fisheye_camera_centre_elevation[i], and fisheye_camera_centre_tilt[i], respectively, all in units of 2⁻¹⁶ degrees, and
- the number of polynomial coefficients numCoeffs and the polynomial coefficients coeffVal[j] (for j ranging from 0 to numCoeffs – 1, inclusive) of the i-th active area, given by fisheye_num_polynomial_coeffs[i] and fisheye_polynomial_coeff[i][j] (for j ranging from 0 to fisheye_num_polynomial_coeffs[i] – 1, inclusive), respectively.

Outputs of this process are:

- sphere coordinates (φ, θ) relative to the global coordinate axes.

The method of converting a sample location of an active area to sphere coordinates is determined as follows:

- If numCoeffs is equal to 0, there is only one method of converting a sample location of an active area to sphere coordinates that is specified, which is to not use polynomial coefficients.
- Otherwise (numCoeffs is not equal to 0), there are two methods of converting a sample location of an active area to sphere coordinates that are specified, which are to not use polynomial coefficients or to use polynomial coefficients. The method using polynomial coefficients is preferred, as this method is intended to provide a more precise model of the fisheye characteristics. However, the other method may also be appropriate for some uses, as it provides a single conversion process that can be used regardless of whether numCoeffs is equal to 0 or not. This Specification does not prescribe which of the two methods is to be used in this case.

The outputs are derived as follows:

- If polynomial coefficients are not used, the angle φ' is derived by

$$\phi' = (\text{Sqrt}((x - x_c \div 2^{16})^2 + (y - y_c \div 2^{16})^2) \div (r_c \div 2^{16})) * (\theta_v \div 2^{16} * \pi \div 180) \div 2 \quad (\text{D-60})$$

- Otherwise (polynomial coefficients are used), the angle φ' is derived by

$$\phi' = \sum_{j=0}^{\text{numCoeffs}-1} ((\text{coeffVal}[j] * 2^{-24}) * (\text{Sqrt}((x - x_c * 2^{-16})^2 + (y - y_c * 2^{-16})^2) \div (r_c * 2^{-16}))^j) \quad (\text{D-61})$$

The outputs are then derived as follows:

$$\begin{aligned}
\theta' &= \text{Atan2}(y - y_c \div 2^{16}, x - x_c \div 2^{16}) \\
x_1 &= \text{Cos}(\phi') \\
y_1 &= \text{Sin}(\phi') * \text{Cos}(\theta') \\
z_1 &= \text{Sin}(\phi') * \text{Sin}(\theta') \\
\alpha &= (\alpha_c \div 2^{16}) * \pi \div 180 \\
\beta &= (\beta_c \div 2^{16}) * \pi \div 180 \\
\gamma &= (\gamma_c \div 2^{16}) * \pi \div 180 \\
x_2 &= \text{Cos}(\beta) * \text{Cos}(\gamma) * x_1 - \text{Cos}(\beta) * \text{Sin}(\gamma) * y_1 + \text{Sin}(\beta) * z_1 \\
y_2 &= (\text{Cos}(\alpha) * \text{Sin}(\gamma) + \text{Sin}(\alpha) * \text{Sin}(\beta) * \text{Cos}(\gamma)) * x_1 + \\
&\quad (\text{Cos}(\alpha) * \text{Cos}(\gamma) - \text{Sin}(\alpha) * \text{Sin}(\beta) * \text{Sin}(\gamma)) * y_1 - \\
&\quad \text{Sin}(\alpha) * \text{Cos}(\beta) * z_1 \\
z_2 &= (\text{Sin}(\alpha) * \text{Sin}(\gamma) - \text{Cos}(\alpha) * \text{Sin}(\beta) * \text{Cos}(\gamma)) * x_1 + \\
&\quad (\text{Sin}(\alpha) * \text{Cos}(\gamma) + \text{Cos}(\alpha) * \text{Sin}(\beta) * \text{Sin}(\gamma)) * y_1 + \\
&\quad \text{Cos}(\alpha) * \text{Cos}(\beta) * z_1 \\
\phi &= \text{Atan2}(y_2, x_2) * 180 \div \pi \\
\theta &= \text{Asin}(z_2) * 180 \div \pi
\end{aligned} \tag{D-62}$$

D.3.42 Regional nesting SEI message semantics

The regional nesting SEI message provides a mechanism to associate SEI messages with regions of the picture. The associated SEI messages are conveyed within the regional nesting SEI message.

A regional nesting SEI message contains one or more SEI messages. When an SEI message is contained in a regional nesting SEI message, the contained SEI message is referred to as a region-nested SEI message. When an SEI message is not contained in a regional nesting SEI message, the SEI message is referred to as a non-region-nested SEI message.

For each region-nested SEI message in a regional nesting SEI message, one or more regions are specified in the regional nesting SEI message, and the semantics of the region-nested SEI message are to be interpreted as applying to each of these regions.

The list `listOfRegionNestableMessageTypes` includes the following types of SEI messages:

- Film grain characteristics SEI message,
- Post filter hint SEI message,
- Tone mapping information SEI message identified with a particular value of `tone_map_id`,
- Chroma resampling filter hint SEI message,
- Knee function information SEI message identified with a particular value of `knee_function_id`,
- Colour remapping information SEI message identified with a particular value of `colour_remap_id`,
- Content colour volume SEI message.

NOTE 1 – SEI messages of each of the following are considered different types of SEI messages: 1) tone mapping information SEI messages with different values of `tone_map_id`, 2) knee function information SEI messages with different values of `knee_function_id`, and 3) colour remapping information SEI messages with different values of `colour_remap_id`.

When an SEI message of a particular type in `listOfRegionNestableMessageTypes` has `film_grain_characteristics_cancel_flag`, `tone_map_cancel_flag`, `knee_function_cancel_flag`, or `colour_remap_cancel_flag` equal to 1, regardless of whether it is region-nested or non-region-nested, it cancels the persistence of all the region-nested SEI messages of that type, regardless of their associated regions. When an SEI message of a particular type having `film_grain_characteristics_persistence_flag`, `tone_map_persistence_flag`, `knee_function_persistence_flag`, or `colour_remap_persistence_flag` equal to 1 is region-nested, the persistence of the SEI message is determined by the semantics of the SEI message, irrespective of which region it applies to.

NOTE 2 – A region-nested SEI message has the same persistence scope as if the SEI message was non-region-nested.

NOTE 3 – A region-nested SEI message does not cancel the persistence of a non-region-nested SEI message of the same type.

The list `listOfAllowedRegionalNestableMessageTypes` includes all the entries in the list `listOfRegionNestableMessageTypes` and also the following additional types of SEI messages:

- User data registered by Rec. ITU-T T.35 SEI message,

- User data unregistered SEI message.

In bitstreams conforming to this version of this Specification, the regional nesting SEI message shall not contain any SEI message that is not in `listOfAllowedRegionNestableMessageTypes`. Decoders encountering a region-nested SEI message that does not belong to `listOfAllowedRegionNestableMessageTypes` shall ignore the region-nested SEI message.

When an access unit contains both region-nested SEI messages of a particular type in `listOfRegionNestableMessageTypes` and non-region-nested SEI messages of the same type, decoders shall ignore either all the region-nested SEI message of that type or all the non-region-nested SEI messages of that type. Unless indicated otherwise by some means not specified in this Specification, when an access unit contains both region-nested SEI messages of a particular type in `listOfRegionNestableMessageTypes` and non-region-nested SEI messages of the same type, the region-nested SEI messages should be preferred to be considered as applicable to the access unit.

A region-nested SEI messages should not be extracted and sent as a non-region-nested SEI message, as the values signalled in the region-nested SEI message may not be applicable outside the indicated regions.

regional_nesting_id contains an identifying number that may be used to identify the purpose of the one or more SEI messages that are region-nested in the regional nesting SEI message. The value of `regional_nesting_id` shall be in the range of 0 to $2^{16} - 1$, inclusive.

Values of `regional_nesting_id` from 0 to 255, inclusive, and from 512 to $2^{15} - 1$, inclusive, may be used as determined by the application. Values of `regional_nesting_id` from 256 to 511, inclusive, and from 2^{15} to $2^{16} - 1$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of `regional_nesting_id` in the range of 256 to 511, inclusive, or in the range of 2^{15} to $2^{16} - 1$, inclusive, shall ignore it.

regional_nesting_num_rect_regions specifies the number of rectangular regions specified in the regional nesting SEI message. The value of `regional_nesting_num_rect_regions` shall be in the range of 1 to 255, inclusive. The value of `regional_nesting_num_rect_regions` equal to 0 is reserved for future use by ITU-T | ISO/IEC and shall not be used in bitstreams conforming to this version of this Specification. Decoders shall ignore regional nesting SEI messages with `regional_nesting_num_rect_regions` equal to 0.

regional_nesting_rect_region_id[i] specifies the identifier for the i-th rectangular region specified in the regional nesting SEI message.

Unless indicated otherwise by some means not specified in this Specification, when a sample belongs to more than one region indicated as applying to more than one region-nested SEI message of a particular type in `listOfRegionNestableMessageTypes`, among these region-nested SEI messages, only those that are associated with the region that has the greatest value of `regional_nesting_rect_region_id[i]` are considered as applying to the sample, while the rest of these region-nested SEI messages are considered as not applying to the sample.

NOTE 4 – When there are more than one of these region-nested SEI messages associated with the region that has the greatest value of `regional_nesting_rect_region_id[i]`, they are identical per other expressed constraints.

It is a requirement of bitstream conformance that the value of `regional_nesting_rect_region_id[i]` shall not be the same for any two different values of i in the range of 0 to `regional_nesting_num_rect_regions` – 1, inclusive, in the regional nesting SEI message.

When a region-nested SEI message of a particular type in `listOfRegionNestableMessageTypes` is indicated as applying to a list of regions `listA` in the current picture and another region-nested SEI message of the same type is indicated as applying to another list of regions `listB` in the current picture, it is a requirement of bitstream conformance that, for any pair of regions formed by choosing one from `listA` and the other from `listB`, the value of `regional_nesting_rect_region_id[i]` of the two regions shall not be the same unless the two regions are identical (i.e., both position and size are the same) and the two region-nested SEI messages are identical.

regional_nesting_rect_left_offset[i], **regional_nesting_rect_right_offset[i]**, **regional_nesting_rect_top_offset[i]**, and **regional_nesting_rect_bottom_offset[i]** specify the coordinates of the i-th rectangular region specified in the SEI message. The offsets for the rectangular region are specified in units of luma samples. The i-th rectangular region contains the luma samples with horizontal picture coordinates from `SubWidthC * regional_nesting_rect_left_offset[i]` to `pic_width_in_luma_samples – (SubWidthC * regional_nesting_rect_right_offset[i] + 1)`, inclusive, and vertical picture coordinates from `SubHeightC * regional_nesting_rect_top_offset[i]` to `pic_height_in_luma_samples – (SubHeightC * regional_nesting_rect_bottom_offset[i] + 1)`, inclusive.

The value of `SubWidthC * (regional_nesting_rect_left_offset[i] + regional_nesting_rect_right_offset[i])` shall be less than `pic_width_in_luma_samples` and the value of `SubHeightC * (regional_nesting_rect_top_offset[i] + regional_nesting_rect_bottom_offset[i])` shall be less than `pic_height_in_luma_samples`.

num_sei_messages_in_regional_nesting_minus1 plus 1 specifies the number of region-nested SEI messages in the regional nesting SEI message. The value of `num_sei_messages_in_regional_nesting_minus1` shall be in the range of 0 to 255, inclusive.

num_regions_for_sei_message[*i*] specifies the number of regions to which the *i*-th region-nested SEI message is associated. When **regional_nesting_num_rect_regions** is greater than 0, the value of **num_regions_for_sei_message**[*i*] shall be in the range of 0 to **regional_nesting_num_rect_regions**, inclusive. When **num_regions_for_sei_message**[*i*] is equal to 0, the *i*-th region-nested SEI message applies to all the regions specified in the regional nesting SEI message.

regional_nesting_sei_region_idx[*i*][*j*] specifies the index, into the list of regions specified in the regional nesting SEI message, of the *j*-th region to which the *i*-th region-nested SEI message in the regional nesting SEI message is associated. The value of **regional_nesting_sei_region_idx**[*i*][*j*] shall be in the range of 0 to **regional_nesting_num_rect_region** – 1, inclusive.

D.3.43 Motion-constrained tile sets extraction information sets SEI message semantics

The motion-constrained tile sets extraction information sets SEI message provides supplemental information that can be used in the motion-constrained tile set (MCTS) sub-bitstream extraction as specified below to generate a conforming bitstream for an MCTS set. The information consists of a number of extraction information sets, each defining a number of MCTS sets and containing RBSP bytes of the replacement VPSs, SPSs, and PPSs to be used during the MCTS sub-bitstream extraction process. Each extraction information set can be shared by multiple MCTS sets, i.e., is used for extraction of any of these MCTS sets.

An MCTS extraction information sets SEI message shall not be present in an access unit unless there is a temporal MCTS SEI message present in the access unit. A temporal MCTS SEI message present in the same access unit as an MCTS extraction information sets SEI message is referred to as the associated temporal MCTS SEI message of the MCTS extraction information sets SEI message.

An MCTS extraction information sets SEI message applies to the same set of pictures as the associated temporal MCTS SEI message, i.e., the **associatedPicSet** of the MCTS extraction information sets SEI message is the same as the **associatedPicSet** of the associated temporal MCTS SEI message.

When more than one MCTS extraction information sets SEI message is present for the pictures of **associatedPicSet**, these MCTS extraction information sets SEI messages shall contain identical content.

NAL units that contain tiles belonging to any particular MCTS **mctsA** shall not contain tiles that do not belong to **mctsA**.

num_info_sets_minus1 plus 1 specifies the number of extraction information sets contained in the MCTS extraction information sets SEI message. The value of **num_info_sets_minus1** shall be in the range of 0 to 2047, inclusive.

The *i*-th extraction information set is assigned an MCTS extraction information set identifier value equal to *i*.

num_mcts_sets_minus1[*i*] plus 1 specifies the number of MCTS sets that share the *i*-th extraction information set. The value of **num_mcts_sets_minus1**[*i*] shall be in the range of 0 to 2047, inclusive.

num_mcts_in_set_minus1[*i*][*j*] plus 1 specifies the number of MCTSs in the *j*-th MCTS set that is associated with the *i*-th extraction information set. The value of **num_mcts_in_set_minus1**[*i*][*j*] shall be in the range of 0 to 511, inclusive.

idx_of_mcts_in_set[*i*][*j*][*k*] specifies the MCTS index of the *k*-th MCTS in the *j*-th MCTS set that is associated with the *i*-th extraction information set. The value of **idx_of_mcts_in_set**[*i*][*j*][*k*] shall be in the range of 0 to 511, inclusive.

slice_reordering_enabled_flag[*i*] equal to 1 specifies that the MCTS sub-bitstream extraction using the *i*-th extraction information set includes reordering of extracted slice segments and that the **slice_segment_address** of the *j*-th slice segment in bitstream order associated with any of the extracted MCTS sets with *j* in the range of 0 to **num_slice_segments_minus1**[*i*] is set to **output_slice_segment_address**[*i*][*j*]. **slice_reordering_enabled_flag**[*i*] equal to 0 indicates that the MCTS sub-bitstream extraction using the *i*-th extraction information set does not include a reordering of extracted slice segments and that the **slice_segment_address** of all extracted slice segments is calculated during extraction.

num_slice_segments_minus1[*i*] plus 1 specifies the number of slice segments associated with any MCTS set of the *i*-th extraction information set when **slice_reordering_enabled_flag**[*i*] is equal to 1. The value of **num_slice_segments_minus1**[*i*] shall be in the range of 0 to 1 024, inclusive.

output_slice_segment_address[*i*][*j*] specifies the slice segment address of the *j*-th slice segment in bitstream order associated with any of the MCTS sets of the *i*-th extraction information set when **slice_reordering_enabled_flag**[*i*] is equal to 1. The length of the **output_slice_segment_address**[*i*][*j*] syntax element is **Ceil(Log2(PicSizeInCtbsY))** bits. The value of **output_slice_segment_address** shall be in the range of 0 to **PicSizeInCtbsY** – 1, inclusive and no value of **output_slice_segment_address**[*i*][*j*] shall be equal to some **output_slice_segment_address**[*i*][*k*] for *j* not equal to *k* in the extraction information set SEI message.

num_vps_in_info_set_minus1[*i*] plus 1 specifies the number of replacement VPSs in the *i*-th extraction information set. The value of **num_vps_in_info_set_minus1**[*i*] shall be in the range of 0 to 15, inclusive.

vps_rbsp_data_length[i][j] specifies the number of RBSP data bytes of the j-th replacement VPS in the i-th extraction information set.

num_sps_in_info_set_minus1[i] plus 1 specifies the number of replacement SPSs in the i-th extraction information set. The value of **num_sps_in_info_set_minus1**[i] shall be in the range of 0 to 15, inclusive.

sps_rbsp_data_length[i][j] specifies the number of RBSP data bytes of the j-th replacement SPS in the i-th extraction information set.

num_pps_in_info_set_minus1[i] plus 1 specifies the number of replacement PPSs in the i-th extraction information set. The value of **num_pps_in_info_set_minus1**[i] shall be in the range of 0 to 63, inclusive.

pps_nuh_temporal_id_plus1[i][j] minus 1 specifies the temporal identifier of the j-th replacement PPS in the i-th extraction information set.

pps_rbsp_data_length[i][j] specifies the number of RBSP data bytes of the j-th replacement PPS in the i-th extraction information set.

mcts_alignment_bit_equal_to_zero shall be equal to 0.

vps_rbsp_data_byte[i][j][k] contains the k-th byte of the RBSP data of the j-th replacement VPS in the i-th extraction information set.

sps_rbsp_data_byte[i][j][k] contains the k-th byte of the RBSP data of the j-th replacement SPS in the i-th extraction information set.

pps_rbsp_data_byte[i][j][k] contains the k-th byte of the RBSP data of the j-th replacement PPS in the i-th extraction information set.

The MCTS sub-bitstream extraction process is specified as follows:

- Let a bitstream **inBitstream**, a target MCTS set index **mctsSetIdxTarget**, a target MCTS extraction information set identifier **mctsEisIdTarget**, and a target highest TemporalId value **mctsTidTarget** be the inputs to the MCTS sub-bitstream extraction process.
- The output of the MCTS sub-bitstream extraction process is a sub-bitstream **outBitstream** derived as follows:

- The bitstream **outBitstream** is set to be identical to the bitstream **inBitstream**.
- The lists **ausWithVps**, **ausWithSps**, and **ausWithPps** are set to consist of all access units within **outBitstream** containing non-VCL NAL units with **nal_unit_type** equal to **VPS_NUT**, **SPS_NUT**, or **PPS_NUT**.
- Remove all SEI NAL units that contain non-MCTS-nested SEI messages.

NOTE 1 – A "smart" bitstream extractor might include appropriate non-MCTS-nested SEI messages in the extracted MCTS sub-bitstream, provided that the SEI messages applicable to the MCTS sub-bitstream were present as MCTS-nested SEI messages in the original bitstream.

- Remove from **outBitstream** all of the following NAL units:
 - VCL NAL units that contain tiles not belonging to any of the MCTSs with MCTS index equal to **idx_of_mcts_in_set**[**mctsEisIdTarget**][**mctsSetIdxTarget**][k] for each value of k in the range of 0 to **num_mcts_in_set_minus1**[**mctsEisIdTarget**][**mctsSetIdxTarget**], inclusive.
 - Non-VCL NAL units with **nal_unit_type** equal to **VPS_NUT**, **SPS_NUT**, or **PPS_NUT**.
- Insert into each access unit within the list **ausWithVps** in **outBitstream** **num_vps_in_info_set_minus1**[**mctsEisIdTarget**] plus 1 VPS NAL units generated from the RBSP data of the list of replacement VPSs in the **mctsEisIdTarget**-th MCTS extraction information set. For each VPS NAL unit that is generated the **nuh_layer_id** is set equal to 0 and **nuh_temporal_id_plus1** is set equal to 1.
- Insert into each access unit within the list **ausWithSps** in **outBitstream** **num_sps_in_info_set_minus1**[**mctsEisIdTarget**] plus 1 SPS NAL units generated from the RBSP data of the list of replacement SPSs in the **mctsEisIdTarget**-th MCTS extraction information set. For each SPS NAL unit that is generated the **nuh_layer_id** is set equal to 0 and **nuh_temporal_id_plus1** is set equal to 1.
- Insert into each access unit within the list **ausWithPps** in **outBitstream** PPS NAL units generated from the RBSP data of the replacement PPSs, in the **mctsEisIdTarget**-th MCTS extraction information set, for which **pps_nuh_temporal_id_plus1**[**mctsEisIdTarget**][j] is less than or equal to **mctsTidTarget**. For each PPS NAL unit that is generated the **nuh_layer_id** is set equal to 0, and for the PPS NAL unit that is generated from the RBSP data of the j-th replacement PPS in the **mctsEisIdTarget**-th MCTS extraction information set, **nuh_temporal_id_plus1** is set equal to **pps_nuh_temporal_id_plus1**[**mctsEisIdTarget**][j].

NOTE 2 – The values of `pps_pic_parameter_set_id` of the replacement PPSs should be identical to the values of `pps_pic_parameter_set_id` of the removed PPSs to retain the value of `slice_pic_parameter_set_id` in slice headers of the original bitstream.

- Remove from `outBitstream` all NAL units with `TemporalId` greater than `mctsTidTarget`.
- If `slice_reordering_enabled_flag[mctsEISIdTarget]` is equal to 0, the CTB raster and tile scanning conversion process as specified in clause 6.5.1 is invoked with the syntax element values of the replacement SPS and PPS as inputs. The output `CtbAddrRsToTs[ctbAddrRs]` is assigned to `extCtbAddrRsToTs[ctbAddrRs]` and `CtbAddrTsToRs[ctbAddrTs]` is assigned to `extCtbAddrTsToRs[ctbAddrTs]`. For each remaining VCL NAL units in `outBitstream`, adjust the slice segment header as follows:
 - For the first VCL NAL unit within each access unit, set the value of `first_slice_segment_in_pic_flag` equal to 1, and set the value of `slice_segment_address` to be equal to 0.
 - For each remaining VCL NAL units in `outBitstream`, let `ctbAddrRs` be the value of the raster scan address of the last CTB in the previous VCL NAL unit in bitstream order within a coded picture of `outBitstream`, set the value of `first_slice_segment_in_pic_flag` equal to 0, and set the value of `slice_segment_address` equal to `extCtbAddrTsToRs[extCtbAddrRsToTs[ctbAddrRs] + 1]`.
- Otherwise (`slice_reordering_enabled_flag[mctsEISIdTarget]` is equal to 1), the following applies:
 - For the k -th VCL NAL units of each access unit in `outBitstream`, set the value of `first_slice_segment_in_pic_flag` equal to 0 and `slice_segment_address` equal to `output_slice_segement_address[mctsEISIdTarget][j]`, where j is in the range of 0 to `num_slice_segments_minus1[mctsEISIdTarget]`, inclusive.
 - Reorder the VCL NAL units within each access unit for ascending values of `slice_segment_address`.
 - For the first VCL NAL unit within each access unit, set the value of `first_slice_segment_in_pic_flag` equal to 1.

NOTE 3 – The extracted MCTS sub-bitstream might have a smaller luma picture size compared to the original bitstream which might require adjustment of the length of `slice_segment_address` and the `byte_alignment()` in slice headers.

It is a requirement of bitstream conformance for the input bitstream that any output sub-bitstream that is the output of the MCTS sub-bitstream extraction process specified in this clause shall be a conforming bitstream.

D.3.44 Motion-constrained tile sets extraction information nesting SEI message semantics

The motion-constrained tile sets extraction information nesting SEI message, also referred to as the MCTS nesting SEI message, provides a mechanism to carry and associate the SEI messages with bitstream subsets corresponding to one or more MCTSs. An SEI message contained in an MCTS nesting SEI message is referred to as MCTS-nested or an MCTS-nested SEI message, and an SEI message that is not contained in an MCTS nesting SEI message is referred to as a non-MCTS-nested SEI message.

In the MCTS sub-bitstream extraction process as specified in the semantics of the MCTS extraction information sets SEI message, the MCTS-nested SEI messages applicable to the MCTSs in an MCTS set in an access unit can be included in the corresponding access unit of the extracted sub-bitstream as non-MCTS-nested SEI messages.

An MCTS-nesting SEI message shall not be present for a picture unless the picture belongs to the `associatedPicSet` of a temporal MCTS SEI message. This temporal MCTS SEI message is referred to as the associated temporal MCTS SEI message of the MCTS-nesting SEI message.

An SEI NAL unit containing an MCTS nesting SEI message shall not contain any other SEI message that is not MCTS-nested in the MCTS nesting SEI message.

all_mcts_flag equal to 0 specifies that the list `nesting_mctsid` is set to consist of the MCTS indices indicated by all instances of `idx_of_associated_mcts[i]` for i from 0 to `num_associated_mcts_minus1`, inclusive. **all_mcts_flag** equal to 1 specifies that the list `nesting_mctsid` consists of the MCTS indices of all the MCTSs indicated by the associated temporal MCTS SEI message.

The MCTS-nested SEI messages apply to all MCTSs for which the MCTS indices are included in the list `nesting_mctsid`.

num_associated_mcts_minus1 plus 1 specifies the number of the following MCTS indices. The value of `num_associated_mcts_minus1` shall be in the range of 0 to 511, inclusive.

idx_of_associated_mcts[i] indicates the MCTS index of the i -th MCTS associated with the following MCTS-nested SEI messages. The value of `idx_of_associated_mcts[i]` shall be in the range of 0 to 511, inclusive.

num_sei_messages_in_mcts_extraction_nesting_minus1 plus 1 specifies the number of the following MCTS-nested SEI messages.

mcts_nesting_zero_bit shall be equal to 0.

D.3.45 SEI manifest SEI message semantics

The SEI manifest SEI message conveys information on SEI messages that are indicated as expected (i.e., likely) to be present or not present. Such information may include the following:

- The indication that certain types of SEI messages are expected (i.e., likely) to be present (although not guaranteed to be present) in the CVS.
- For each type of SEI message that is indicated as expected (i.e., likely) to be present in the CVS, the degree of expressed necessity of interpretation of the SEI messages of this type, as follows:
 - The degree of necessity of interpretation of an SEI message type may be indicated as "necessary", "unnecessary", or "undetermined".
 - An SEI message is indicated by the encoder (i.e., the content producer) as being "necessary" when the information conveyed by the SEI message is considered as necessary for interpretation by the decoder or receiving system in order to properly process the content and enable an adequate user experience; it does not mean that the bitstream is required to contain the SEI message in order to be a conforming bitstream. It is at the discretion of the encoder to determine which SEI messages are to be considered as necessary in a particular CVS. However, it is suggested that some SEI messages, such as the frame packing arrangement, segmented rectangular frame packing arrangement, and omnidirectional projection indication SEI messages, should typically be considered as necessary.
- The indication that certain types of SEI messages are expected (i.e., likely) not to be present (although not guaranteed not to be present) in the CVS.

NOTE – An example of such a usage of an SEI manifest SEI message is to express the expectation that there are no frame packing arrangement SEI messages, segmented rectangular frame packing arrangement SEI messages, display orientation SEI messages, or omnidirectional projection indication SEI messages in the CVS, and therefore that the rendering of the decoded video pictures for display purposes would not need any of the additional post-processing that is commonly associated with the interpretation of these SEI messages.

The content of an SEI manifest SEI message may, for example, be used by transport-layer or systems-layer processing elements to determine whether the CVS is suitable for delivery to a receiving and decoding system, based on whether the receiving system can properly process the CVS to enable an adequate user experience or whether the CVS satisfies the application needs.

When an SEI manifest SEI message is present in any access unit of a CVS, an SEI manifest SEI message shall be present in the first access unit of the CVS. The SEI manifest SEI message persists in decoding order from the current access unit until the end of the CVS. When there are multiple SEI manifest SEI messages present in a CVS, they shall have the same content.

An SEI NAL unit containing an SEI manifest SEI message shall not contain any other SEI messages other than SEI prefix indication SEI messages. When present in an SEI NAL unit, the SEI manifest SEI message shall be the first SEI message in the SEI NAL unit.

manifest_num_sei_msg_types specifies the number of types of SEI messages for which information is provided in the SEI manifest SEI message.

manifest_sei_payload_type[i] indicates the payloadType value of the i-th type of SEI message for which information is provided in the SEI manifest SEI message. The values of **manifest_sei_payload_type[m]** and **manifest_sei_payload_type[n]** shall not be identical when m is not equal to n.

manifest_sei_description[i] provides information on SEI messages with payloadType equal to **manifest_sei_payload_type[i]** as specified in Table D.23.

Table D.23 – Interpretation of manifest_sei_description[i]

Value	Description
0	Indicates that there is no SEI message with payloadType equal to manifest_sei_payload_type[i] expected to be present in the CVS.
1	Indicates that there are SEI messages with payloadType equal to manifest_sei_payload_type[i] expected to be present in the CVS, and these SEI messages are considered as necessary.
2	Indicates that there are SEI messages with payloadType equal to manifest_sei_payload_type[i] expected to be present in the CVS, and these SEI messages are considered as unnecessary.

3	Indicates that there are SEI messages with payloadType equal to manifest_sei_payload_type[i] expected to be present in the CVS, and the necessity of these SEI messages is undetermined.
4..255	Reserved

The value of manifest_sei_description[i] shall be in the range of 0 to 3, inclusive, in bitstreams conforming to this version of this Specification. Other values for manifest_sei_description[i] are reserved for future use by ITU-T | ISO/IEC. Decoders shall allow the value of manifest_sei_description[i] greater than or equal to 4 to appear in the syntax and shall ignore all information for payloadType equal to manifest_sei_payload_type[i] signalled in the SEI manifest SEI message and shall ignore all SEI prefix indication SEI messages with prefix_sei_payload_type equal to manifest_sei_payload_type[i] when manifest_sei_description[i] is greater than or equal to 4.

D.3.46 SEI prefix indication SEI message semantics

The SEI prefix indication SEI message carries one or more SEI prefix indications for SEI messages of a particular value of payloadType. Each SEI prefix indication is a bit string that follows the SEI payload syntax of that value of payloadType and contains a number of complete syntax elements starting from the first syntax element in the SEI payload.

Each SEI prefix indication for an SEI message of a particular value of payloadType indicates that one or more SEI messages of this value of payloadType are expected (i.e., likely) to be present in the CVS and to start with the provided bit string. A starting bit string would typically contain only a true subset of an SEI payload of the type of SEI message indicated by the payloadType, may contain a complete SEI payload, and shall not contain more than a complete SEI payload. It is not prohibited for SEI messages of the indicated value of payloadType to be present that do not start with any of the indicated bit strings.

These SEI prefix indications should provide sufficient information for indicating what type of processing is needed or what type of content is included. The former (type of processing) indicates decoder-side processing capability, e.g., whether some type of frame unpacking is needed. The latter (type of content) indicates, for example, whether the bitstream contains subtitle captions in a particular language.

The content of an SEI prefix indication SEI message may, for example, be used by transport-layer or systems-layer processing elements to determine whether the CVS is suitable for delivery to a receiving and decoding system, based on whether the receiving system can properly process the CVS to enable an adequate user experience or whether the CVS satisfies the application needs (as determined in some manner by external means outside the scope of this Specification).

In one example, when the payloadType indicates the frame packing arrangement SEI message, an SEI prefix indication should include up to at least the syntax element frame_packing_arrangement_type; and when the payloadType indicates the omnidirectional projection indication SEI message, an SEI prefix indication should include up to at least the syntax element projection_type.

In another example, for user data registered SEI messages that are used to carry captioning information, an SEI prefix indication should include up to at least the language code; and for user data unregistered SEI messages extended for private use, an SEI prefix indication should include up to at least the UUID.

When an SEI prefix indication SEI message is present in any access unit of a CVS, an SEI prefix indication SEI message shall be present in the first access unit of the CVS. The SEI prefix indication SEI message persists in decoding order from the current access unit until the end of the CVS. When there are multiple SEI prefix indication SEI messages present in a CVS for a particular value of payloadType, they shall have the same content.

An SEI NAL unit containing an SEI prefix indication SEI message for a particular value of payloadType shall not contain any other SEI messages other than an SEI manifest SEI message and SEI prefix indication SEI messages for other values of payloadType.

prefix_sei_payload_type indicates the payloadType value of the SEI messages for which one or more SEI prefix indications are provided in the SEI prefix indication SEI message. When an SEI manifest SEI message is also present for the CVS, the value of prefix_sei_payload_type shall be equal to one of the manifest_sei_payload_type[m] values for which manifest_sei_description[m] is equal to 1 to 3, inclusive, as indicated by an SEI manifest SEI message that applies to the CVS.

num_sei_prefix_indications_minus1 plus 1 specifies the number of SEI prefix indications.

num_bits_in_prefix_indication_minus1[i] plus 1 specifies the number of bits in the i-th SEI prefix indication.

sei_prefix_data_bit[i][j] specifies the j-th bit of the i-th SEI prefix indication.

The bits sei_prefix_data_bit[i][j] for j ranging from 0 to num_bits_in_prefix_indication_minus1[i], inclusive, follow the syntax of the SEI payload with payloadType equal to prefix_sei_payload_type, and contain a number of complete

syntax elements starting from the first syntax element in the SEI payload syntax, and may or may not contain all the syntax elements in the SEI payload syntax. The last bit of these bits (i.e., the bit `sei_prefix_data_bit[i][num_bits_in_prefix_indication_minus1[i]]`) shall be the last bit of a syntax element in the SEI payload syntax, unless it is a bit within an `itu_t_t35_payload_byte` or `user_data_payload_byte`.

NOTE – The exception for `itu_t_t35_payload_byte` and `user_data_payload_byte` is provided because these syntax elements may contain externally-specified syntax elements, and the determination of the boundaries of such externally-specified syntax elements is a matter outside the scope of this Specification.

`byte_alignment_bit_equal_to_one` shall be equal to 1.

D.3.47 Annotated regions SEI message semantics

The annotated regions SEI message carries parameters that identify annotated regions using bounding boxes representing the size and location of identified objects.

`ar_cancel_flag` equal to 1 indicates that the SEI message cancels the persistence of any previous annotated regions SEI message that is associated with one or more layers to which the annotated regions SEI message applies. **`ar_cancel_flag`** equal to 0 indicates that annotated regions information follows.

When **`ar_cancel_flag`** equal to 1 or a new CLVS of the current layer begins, the variables `LabelAssigned[i]`, `ObjectTracked[i]`, and `ObjectBoundingBoxAvail` are set equal to 0 for `i` in the range of 0 to 255, inclusive.

Let `picA` be the current picture. Each region identified in the annotated regions SEI message persists for the current layer in output order until any of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture `picB` in the current layer in an access unit containing an annotated regions SEI message that is applicable to the current layer is output for which `PicOrderCnt(picB)` is greater than `PicOrderCnt(picA)`, where `PicOrderCnt(picB)` and `PicOrderCnt(picA)` are the `PicOrderCntVal` values of `picB` and `picA`, and the semantics of the annotated regions SEI message for `PicB` cancels the persistence of the region identified in the annotated regions SEI message for `PicA`.

`ar_not_optimized_for_viewing_flag` equal to 1 indicates that the decoded pictures that the annotated regions SEI message applies to are not optimized for user viewing, but rather are optimized for some other purpose such as algorithmic object classification performance. **`ar_not_optimized_for_viewing_flag`** equal to 0 indicates that the decoded pictures that the annotated regions SEI message applies to may or may not be optimized for user viewing.

`ar_true_motion_flag` equal to 1 indicates that the motion information in the coded pictures that the annotated regions SEI message applies to was selected with a goal of accurately representing object motion for objects in the annotated regions. **`ar_true_motion_flag`** equal to 0 indicates that the motion information in the coded pictures that the annotated regions SEI message applies to may or may not be selected with a goal of accurately representing object motion for objects in the annotated regions.

`ar_occluded_object_flag` equal to 1 indicates that the `ar_bounding_box_top[ar_object_idx[i]]`, `ar_bounding_box_left[ar_object_idx[i]]`, `ar_bounding_box_width[ar_object_idx[i]]`, and `ar_bounding_box_height[ar_object_idx[i]]` syntax elements represent the size and location of an object or a portion of an object that may not be visible or may be only partially visible within the cropped decoded picture. **`ar_occluded_object_flag`** equal to 0 indicates that the `ar_bounding_box_top[ar_object_idx[i]]`, `ar_bounding_box_left[ar_object_idx[i]]`, `ar_bounding_box_width[ar_object_idx[i]]`, and `ar_bounding_box_height[ar_object_idx[i]]` syntax elements represent the size and location of an object that is entirely visible within the cropped decoded picture. It is a requirement of bitstream conformance that the value of **`ar_occluded_object_flag`** shall be the same for all `annotated_regions()` syntax structures within a CLVS.

`ar_partial_object_flag_present_flag` equal to 1 indicates that `ar_partial_object_flag[ar_object_idx[i]]` syntax elements are present. **`ar_partial_object_flag_present_flag`** equal to 0 indicates that `ar_partial_object_flag[ar_object_idx[i]]` syntax elements are not present. It is a requirement of bitstream conformance that the value of **`ar_partial_object_flag_present_flag`** shall be the same for all `annotated_regions()` syntax structures within a CLVS.

`ar_object_label_present_flag` equal to 1 indicates that label information corresponding to objects in the annotated regions is present. **`ar_object_label_present_flag`** equal to 0 indicates that label information corresponding to the objects in the annotated regions is not present.

`ar_object_confidence_info_present_flag` equal to 1 indicates that `ar_object_confidence[ar_object_idx[i]]` syntax elements are present. **`ar_object_confidence_info_present_flag`** equal to 0 indicates that `ar_object_confidence[ar_object_idx[i]]` syntax elements are not present. It is a requirement of bitstream conformance that the value of **`ar_object_confidence_present_flag`** shall be the same for all `annotated_regions()` syntax structures within a CLVS.

ar_object_confidence_length_minus1 plus 1 specifies the length, in bits, of the **ar_object_confidence[ar_object_idx[i]]** syntax elements. It is a requirement of bitstream conformance that the value of **ar_object_confidence_length_minus1** shall be the same for all annotated_regions() syntax structures within a CLVS.

ar_object_label_language_present_flag equal to 1 indicates that the **ar_object_label_language** syntax element is present. **ar_object_label_language_present_flag** equal to 0 indicates that the **ar_object_label_language** syntax element is not present.

ar_bit_equal_to_zero shall be equal to zero.

ar_object_label_language contains a language tag as specified by IETF RFC 5646 followed by a null termination byte equal to 0x00. The length of the **ar_object_label_language** syntax element shall be less than or equal to 255 bytes, not including the null termination byte. When not present, the language of the label is unspecified.

ar_num_label_updates indicates the total number of labels associated with the annotated regions that are signalled. The value of **ar_num_label_updates** shall be in the range of 0 to 255, inclusive.

ar_label_idx[i] indicates the index of the signalled label. The value of **ar_label_idx[i]** shall be in the range of 0 to 255, inclusive.

ar_label_cancel_flag equal to 1 cancels the persistence scope of the **ar_label_idx[i]**-th label. **ar_label_cancel_flag** equal to 0 indicates that the **ar_label_idx[i]**-th label is assigned a signalled value.

LabelAssigned[ar_label_idx[i]] equal to 1 indicates that the **ar_label_idx[i]**-th label is assigned. **LabelAssigned[ar_label_idx[i]]** equal to 0 indicates that the **ar_label_idx[i]**-th label is not assigned.

ar_label[ar_label_idx[i]] specifies the contents of the **ar_label_idx[i]**-th label. The length of the **ar_label[ar_label_idx[i]]** syntax element shall be less than or equal to 255 bytes, not including the null termination byte.

ar_num_object_updates indicates the number of object updates to be signalled. **ar_num_object_updates** shall be in the range of 0 to 255, inclusive.

ar_object_idx[i] is the index of the object parameters to be signalled. **ar_object_idx[i]** shall be in the range of 0 to 255, inclusive.

ar_object_cancel_flag equal to 1 cancels the persistence scope of the **ar_object_idx[i]**-th object. **ar_object_cancel_flag** equal to 0 indicates that parameters associated with the **ar_object_idx[i]**-th object tracked object are signalled.

ObjectTracked[ar_object_idx[i]] equal to 1 indicates that the **object_idx[i]**-th object is tracked. **ObjectTracked[ar_object_idx[i]]** equal to 0 indicates that the **object_idx[i]**-th object is not tracked.

ar_object_label_update_flag equal to 1 indicates that an object label is signalled. **ar_object_label_update_flag** equal to 0 indicates that an object label is not signalled.

ar_object_label_idx[ar_object_idx[i]] indicates the index of the label corresponding to the **ar_object_idx[i]**-th object. When **ar_object_label_idx[ar_object_idx[i]]** is not present, its value is inferred from a previous annotated regions SEI message in output order in the same CLVS, if any. The value of **ar_object_label_idx[ar_object_idx[i]]** shall be in the range of 0 to 255, inclusive.

ar_bounding_box_update_flag equal to 1 indicates that object bounding box parameters are signalled. **ar_bounding_box_update_flag** equal to 0 indicates that object bounding box parameters are not signalled.

ar_bounding_box_cancel_flag equal to 1 cancels the persistence scope of the **ar_bounding_box_top[ar_object_idx[i]]**, **ar_bounding_box_left[ar_object_idx[i]]**, **ar_bounding_box_width[ar_object_idx[i]]**, **ar_bounding_box_height[ar_object_idx[i]]**, **ar_partial_object_flag[ar_object_idx[i]]**, and **ar_object_confidence[ar_object_idx[i]]**. **ar_bounding_box_cancel_flag** equal to 0 indicates that **ar_bounding_box_top[ar_object_idx[i]]**, **ar_bounding_box_left[ar_object_idx[i]]**, **ar_bounding_box_width[ar_object_idx[i]]**, **ar_bounding_box_height[ar_object_idx[i]]**, **ar_partial_object_flag[ar_object_idx[i]]**, and **ar_object_confidence[ar_object_idx[i]]** syntax elements are signalled.

ObjectBoundingBoxAvail[ar_object_idx[i]] equal to 1 indicates that the bounding box information of the **object_idx[i]**-th object is signalled. **ObjectBoundingBoxAvail[ar_object_idx[i]]** equal to 0 indicates that the bounding box information of the **object_idx[i]**-th object is not signalled.

ar_bounding_box_top[ar_object_idx[i]], **ar_bounding_box_left[ar_object_idx[i]]**, **ar_bounding_box_width[ar_object_idx[i]]**, and **ar_bounding_box_height[ar_object_idx[i]]** specify the coordinates of the top-left corner and the width and height, respectively, of the bounding box of the **ar_object_idx[i]**-th object in the cropped decoded picture, relative to the conformance cropping window specified by the active SPS.

Let **croppedWidth** and **croppedHeight** be the width and height, respectively, of the cropped decoded picture in units of luma samples, as specified by Equations D-28 and D-29.

The value of `ar_bounding_box_left[ar_object_idx[i]]` shall be in the range of 0 to `croppedWidth / SubWidthC - 1`, inclusive.

The value of `ar_bounding_box_top[ar_object_idx[i]]` shall be in the range of 0 to `croppedHeight / SubHeightC - 1`, inclusive.

The value of `ar_bounding_box_width[ar_object_idx[i]]` shall be in the range of 0 to `croppedWidth / SubWidthC - 1`, inclusive.

The value of `ar_bounding_box_height[ar_object_idx[i]]` shall be in the range of 0 to `croppedHeight / SubHeightC - 1`, inclusive.

The identified object rectangle contains the luma samples with horizontal picture coordinates from `SubWidthC * (conf_win_left_offset + ar_bounding_box_left[ar_object_idx[i]])` to `SubWidthC * (conf_win_left_offset + ar_bounding_box_left[ar_object_idx[i]] + ar_bounding_box_width[ar_object_idx[i]] - 1`, inclusive, and vertical picture coordinates from `SubHeightC * (conf_win_top_offset + ar_bounding_box_top[ar_object_idx[i]])` to `SubHeightC * (conf_win_top_offset + ar_bounding_box_top[ar_object_idx[i]] + ar_bounding_box_height[ar_object_idx[i]] - 1`, inclusive.

When `ChromaArrayType` is not equal to 0, the corresponding specified samples of the two chroma arrays are the samples having picture coordinates (`x / SubWidthC, y / SubHeightC`), where (`x, y`) are the picture coordinates of the specified luma samples.

The values of `ar_bounding_box_top[ar_object_idx[i]]`, `ar_bounding_box_left[ar_object_idx[i]]`, `ar_bounding_box_width[ar_object_idx[i]]` and `ar_bounding_box_height[ar_object_idx[i]]` persist in output order within the CLVS for each value of `ar_object_idx[i]`. When not present, the values of `ar_bounding_box_top[ar_object_idx[i]]`, `ar_bounding_box_left[ar_object_idx[i]]`, `ar_bounding_box_width[ar_object_idx[i]]` or `ar_bounding_box_height[ar_object_idx[i]]` are inferred from a previous annotated regions SEI message in output order in the CLVS, if any.

`ar_partial_object_flag[ar_object_idx[i]]` equal to 1 indicates that the `ar_bounding_box_top[ar_object_idx[i]]`, `ar_bounding_box_left[ar_object_idx[i]]`, `ar_bounding_box_width[ar_object_idx[i]]` and `ar_bounding_box_height[ar_object_idx[i]]` syntax elements represent the size and location of an object that is only partially visible within the cropped decoded picture. `ar_partial_object_flag[ar_object_idx[i]]` equal to 0 indicates that the `ar_bounding_box_top[ar_object_idx[i]]`, `ar_bounding_box_left[ar_object_idx[i]]`, `ar_bounding_box_width[ar_object_idx[i]]` and `ar_bounding_box_height[ar_object_idx[i]]` syntax elements represent the size and location of an object that may or may not be only partially visible within the cropped decoded picture. When not present, the value of `ar_partial_object_flag[ar_object_idx[i]]` is inferred from a previous annotated regions SEI message in output order in the CLVS, if any.

`ar_object_confidence[ar_object_idx[i]]` indicates the degree of confidence associated with the `ar_object_idx[i]`-th object, in units of $2^{-(\text{ar_object_confidence_length_minus1} + 1)}$, such that a higher value of `ar_object_confidence[ar_object_idx[i]]` indicates a higher degree of confidence. The length of the `ar_object_confidence[ar_object_idx[i]]` syntax element is `ar_object_confidence_length_minus1 + 1` bits. When not present, the value of `object_confidence[ar_object_idx[i]]` is inferred from a previous annotated regions SEI message in output order in the CLVS, if any.

D.3.48 Shutter interval information SEI message semantics

The shutter interval information SEI message indicates the shutter interval for the associated video source pictures prior to encoding, e.g., for camera-captured content, the shutter interval is amount of time that an image sensor is exposed to produce each source picture.

When a shutter interval information SEI message is present for any picture of a CLVS of a particular layer, a shutter interval information SEI message shall be present for the first picture of the CLVS. The shutter interval information SEI message persists for the current layer in decoding order from the current picture until the end of the CLVS. All shutter interval information SEI messages that apply to the same CLVS shall have the same content.

sii_time_scale specifies the number of time units that pass in one second. The value of `sii_time_scale` shall be greater than 0. For example, a time coordinate system that measures time using a 27 MHz clock has an `sii_time_scale` of 27 000 000.

fixed_shutter_interval_within_clvs_flag equal to 1 specifies that the indicated shutter interval is the same for all temporal sub-layers in the CLVS. `fixed_shutter_interval_within_clvs_flag` equal to 0 specifies that the indicated shutter interval may not be the same for all temporal sub-layers in the CLVS. When the value of `sps_max_sub_layers_minus1` is equal to 0, the value of `fixed_shutter_interval_within_clvs_flag` shall be equal to 1.

sii_num_units_in_shutter_interval, when `fixed_shutter_interval_within_clvs_flag` is equal to 1, specifies the number of time units of a clock operating at the frequency `sii_time_scale` Hz that corresponds to the indicated shutter interval of each picture in the CLVS. The value 0 may be used to indicate that the associated video content contains screen capture content, computer generated content, or other non-camera-captured content.

The indicated shutter interval, denoted by the variable `shutterInterval`, in units of seconds, is equal to the quotient of `sii_num_units_in_shutter_interval` divided by `sii_time_scale`. For example, to represent a shutter interval equal to 0.04 seconds, `sii_time_scale` may be equal to 27 000 000 and `sii_num_units_in_shutter_interval` may be equal to 1 080 000.

`sii_max_sub_layers_minus1` plus 1 specifies the maximum number of temporal sub-layers that may be present in each CLVS referring to the SPS. The value of `sii_max_sub_layers_minus1` shall be equal to the value of `sps_max_sub_layers_minus1` in the SPS.

NOTE – For example, the information conveyed in this SEI message is intended to be adequate for purposes corresponding to the use of ATSC A/341:2019 Annex D when `sii_max_sub_layers_minus1` is equal to 1 and `fixed_shutter_interval_within_clvs_flag` is equal to 0.

`sub_layer_num_units_in_shutter_interval[i]`, when present, specifies the number of time units of a clock operating at the frequency `sii_time_scale` Hz that corresponds to the shutter interval of each picture in the sub-layer representation with `TemporalId` equal to `i` in the CLVS. The sub-layer shutter interval for the sub-layer representation with `TemporalId` equal to `i`, denoted by the variable `subLayerShutterInterval[i]`, in units of seconds, is equal to the quotient of `sub_layer_num_units_in_shutter_interval[i]` divided by `sii_time_scale`.

The variable `subLayerShutterInterval[i]`, corresponding to the indicated shutter interval of each picture in the sub-layer representation with `TemporalId` equal to `i` in the CLVS, is thus derived as follows:

```

if( fixed_shutter_interval_within_clvs_flag )
    subLayerShutterInterval[ i ] = sii_num_units_in_shutter_interval ÷ sii_time_scale
else
    subLayerShutterInterval[ i ] = sub_layer_num_units_in_shutter_interval[ i ] ÷ sii_time_scale

```

(D-63)

D.3.49 Reserved SEI message semantics

The reserved SEI message consists of data reserved for future backward-compatible use by ITU-T | ISO/IEC. It is a requirement of bitstream conformance that bitstreams shall not contain reserved SEI messages until and unless the use of such messages has been specified by ITU-T | ISO/IEC. Decoders shall ignore reserved SEI messages.

Annex E

Video usability information

(This annex forms an integral part of this Recommendation | International Standard.)

E.1 General

This annex specifies syntax and semantics of the VUI parameters of the SPSs.

VUI parameters are not required for constructing the luma or chroma samples by the decoding process. Conforming decoders are not required to process this information for output order conformance to this Specification (see Annex C and clause F.13 for the specification of output order conformance). Some VUI parameters are required to check bitstream conformance and for output timing decoder conformance.

In this annex, specification for presence of VUI parameters is also satisfied when those parameters (or some subset of them) are conveyed to decoders (or to the HRD) by other means not specified in this Specification. When present in the bitstream, VUI parameters shall follow the syntax and semantics specified in this annex. When the content of VUI parameters is conveyed for the application by some means other than presence within the bitstream, the representation of the content of the VUI parameters is not required to use the same syntax specified in this annex. For the purpose of counting bits, only the appropriate bits that are actually present in the bitstream are counted.

E.3 VUI semantics

E.3.1 VUI parameters semantics

aspect_ratio_info_present_flag equal to 1 specifies that **aspect_ratio_idc** is present. **aspect_ratio_info_present_flag** equal to 0 specifies that **aspect_ratio_idc** is not present.

aspect_ratio_idc specifies the value of the sample aspect ratio of the luma samples. Table E.1 shows the meaning of the code. When **aspect_ratio_idc** indicates EXTENDED_SAR, the sample aspect ratio is represented by **sar_width**: **sar_height**. When the **aspect_ratio_idc** syntax element is not present, the value of **aspect_ratio_idc** is inferred to be equal to 0. Values of **aspect_ratio_idc** in the range of 17 to 254, inclusive, are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall interpret values of **aspect_ratio_idc** in the range of 17 to 254, inclusive, as equivalent to the value 0.

Table E.1 – Interpretation of sample aspect ratio indicator

aspect_ratio_idc	Sample aspect ratio	Examples of use (informative)
0	Unspecified	
1	1:1 ("square")	7680x4320 16:9 frame without horizontal overscan 3840x2160 16:9 frame without horizontal overscan 1280x720 16:9 frame without horizontal overscan 1920x1080 16:9 frame without horizontal overscan (cropped from 1920x1088) 640x480 4:3 frame without horizontal overscan
2	12:11	720x576 4:3 frame with horizontal overscan 352x288 4:3 frame without horizontal overscan
3	10:11	720x480 4:3 frame with horizontal overscan 352x240 4:3 frame without horizontal overscan
4	16:11	720x576 16:9 frame with horizontal overscan 528x576 4:3 frame without horizontal overscan
5	40:33	720x480 16:9 frame with horizontal overscan 528x480 4:3 frame without horizontal overscan
6	24:11	352x576 4:3 frame without horizontal overscan 480x576 16:9 frame with horizontal overscan
7	20:11	352x480 4:3 frame without horizontal overscan 480x480 16:9 frame with horizontal overscan
8	32:11	352x576 16:9 frame without horizontal overscan
9	80:33	352x480 16:9 frame without horizontal overscan
10	18:11	480x576 4:3 frame with horizontal overscan
11	15:11	480x480 4:3 frame with horizontal overscan
12	64:33	528x576 16:9 frame without horizontal overscan
13	160:99	528x480 16:9 frame without horizontal overscan
14	4:3	1440x1080 16:9 frame without horizontal overscan
15	3:2	1280x1080 16:9 frame without horizontal overscan
16	2:1	960x1080 16:9 frame without horizontal overscan
17..254	Reserved	
255	EXTENDED_SAR	

NOTE 1 – For the examples in Table E.1, the term "without horizontal overscan" refers to display processes in which the display area matches the area of the cropped decoded pictures and the term "with horizontal overscan" refers to display processes in which some parts near the left or right border of the cropped decoded pictures are not visible in the display area. As an example, the entry "720x576 4:3 frame with horizontal overscan" for aspect_ratio_idc equal to 2 refers to having an area of 704x576 luma samples (which has an aspect ratio of 4:3) of the cropped decoded frame (720x576 luma samples) that is visible in the display area.

NOTE 2 – For the examples in Table E.1, the frame spatial resolutions shown as examples of use would be the dimensions of the conformance cropping window when field_seq_flag is equal to 0 and would have twice the height of the dimensions of the conformance cropping window when field_seq_flag is equal to 1.

sar_width indicates the horizontal size of the sample aspect ratio (in arbitrary units).

sar_height indicates the vertical size of the sample aspect ratio (in the same arbitrary units as sar_width).

sar_width and sar_height shall be relatively prime or equal to 0. When aspect_ratio_idc is equal to 0 or sar_width is equal to 0 or sar_height is equal to 0, the sample aspect ratio is unspecified in this Specification.

overscan_info_present_flag equal to 1 specifies that the overscan_appropriate_flag is present. When overscan_info_present_flag is equal to 0 or is not present, the preferred display method for the video signal is unspecified.

overscan_appropriate_flag equal to 1 indicates that the cropped decoded pictures output are suitable for display using overscan. overscan_appropriate_flag equal to 0 indicates that the cropped decoded pictures output contain visually important information in the entire region out to the edges of the conformance cropping window of the picture, such that the cropped decoded pictures output should not be displayed using overscan. Instead, they should be displayed using either an exact match between the display area and the conformance cropping window, or using underscan. As used in this paragraph, the term "overscan" refers to display processes in which some parts near the borders of the cropped decoded

pictures are not visible in the display area. The term "underscan" describes display processes in which the entire cropped decoded pictures are visible in the display area, but they do not cover the entire display area. For display processes that neither use overscan nor underscan, the display area exactly matches the area of the cropped decoded pictures.

NOTE 3 – For example, `overscan_appropriate_flag` equal to 1 might be used for entertainment television programming, or for a live view of people in a videoconference and `overscan_appropriate_flag` equal to 0 might be used for computer screen capture or security camera content.

`video_signal_type_present_flag` equal to 1 specifies that `video_format`, `video_full_range_flag` and `colour_description_present_flag` are present. `video_signal_type_present_flag` equal to 0, specify that `video_format`, `video_full_range_flag` and `colour_description_present_flag` are not present.

NOTE 4 – Some of the semantics of video signal type parameters associated with `video_signal_type_present_flag` equal to 1 are expressed in terms of the properties of source pictures prior to operation of the encoding process, which is outside the scope of this Specification. This is partly for historical reasons and due to the common general practice of how the indicated data is typically described in industry publications. The actual intent for providing this syntax in the bitstream is to assist decoding systems to properly interpret and make effective use of the decoded video pictures, e.g., for use by the display process (which is also outside the scope of this Specification, but for which having an indication of how the pictures should be interpreted is important).

`video_format` indicates the representation of the pictures as specified in Table E.2, before being coded in accordance with this Specification. When the `video_format` syntax element is not present, the value of `video_format` is inferred to be equal to 5. The values 6 and 7 for `video_format` are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall interpret the values 6 and 7 for `video_format` as equivalent to the value 5.

Table E.2 – Meaning of `video_format`

<code>video_format</code>	Meaning
0	Component
1	PAL
2	NTSC
3	SECAM
4	MAC
5	Unspecified video format

`video_full_range_flag` indicates the black level and range of the luma and chroma signals as derived from E'_Y , E'_{PB} , and E'_{PR} or E'_R , E'_G , and E'_B real-valued component signals.

When the `video_full_range_flag` syntax element is not present, the value of `video_full_range_flag` is inferred to be equal to 0.

`colour_description_present_flag` equal to 1 specifies that `colour_primaries`, `transfer_characteristics`, and `matrix_coeffs` are present. `colour_description_present_flag` equal to 0 specifies that `colour_primaries`, `transfer_characteristics`, and `matrix_coeffs` are not present.

`colour_primaries` indicates the chromaticity coordinates of the source primaries as specified in Table E.3 in terms of the CIE 1931 definition of x and y as specified in ISO 11664-1.

When the `colour_primaries` syntax element is not present, the value of `colour_primaries` is inferred to be equal to 2 (the chromaticity is unspecified or is determined by the application). Values of `colour_primaries` that are identified as reserved in Table E.3 are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall interpret reserved values of `colour_primaries` as equivalent to the value 2.

transfer_characteristics, as specified in Table E.4, either indicates the reference opto-electronic transfer characteristic function of the source picture as a function of a source input linear optical intensity L_c with a nominal real-valued range of 0 to 1 or indicates the inverse of the reference electro-optical transfer characteristic function as a function of an output linear optical intensity L_o with a nominal real-valued range of 0 to 1. For interpretation of entries in Table E.4 that are expressed in terms of multiple curve segments parameterized by the variable α over a region bounded by the variable β or by the variables β and γ , the values of α and β are defined to be the positive constants necessary for the curve segments that meet at the value β to have continuity of value and continuity of slope at the value β , and the value of γ , when applicable, is defined to be the positive constant necessary for the associated curve segments to meet at the value γ . For example, for transfer_characteristics equal to 1, 6, 11, 14, or 15, α has the value $1 + 5.5 * \beta = 1.099\ 296\ 826\ 809\ 442\dots$ and β has the value 0.018 053 968 510 807....

When the transfer_characteristics syntax element is not present, the value of transfer_characteristics is inferred to be equal to 2 (the transfer characteristics are unspecified or are determined by the application). Values of transfer_characteristics that are identified as reserved in Table E.4 are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall interpret reserved values of transfer_characteristics as equivalent to the value 2.

NOTE 5 – As indicated in Table E.4, some values of transfer_characteristics are defined in terms of a reference opto-electronic transfer characteristic function and others are defined in terms of a reference electro-optical transfer characteristic function, according to the convention that has been applied in other Specifications. In the cases of Rec. ITU-R BT.709-6 and Rec. ITU-R BT.2020-2 (which may be indicated by transfer_characteristics equal to 1, 6, 14, or 15), although the value is defined in terms of a reference opto-electronic transfer characteristic function, a suggested corresponding reference electro-optical transfer characteristic function for flat panel displays used in HDTV studio production has been specified in Rec. ITU-R BT.1886-0.

17	$V = (48 * L_o \div 52.37)^{(1 \div 2.6)}$ for all values of L_o for which L_o equal to 1 for peak white is ordinarily intended to correspond to a reference output luminance level of 48 candelas per square metre	SMPTE ST 428-1 (2006)
18	$V = a * \text{Ln}(12 * L_c - b) + c$ for $1 \geq L_c > 1 \div 12$ $V = \text{Sqrt}(3) * L_c^{0.5}$ for $1 \div 12 \geq L_c \geq 0$ $a = 0.178\,832\,77$, $b = 0.284\,668\,92$, $c = 0.559\,910\,73$	Association of Radio Industries and Businesses (ARIB) STD-B67 Rec. ITU-R BT.2100-2 hybrid log-gamma (HLG) system
19..255	Reserved	For future use by ITU-T ISO/IEC

NOTE 6 – For transfer_characteristics equal to 18, the equations given in Table E.4 are normalized for a source input linear optical intensity L_c with a nominal real-valued range of 0 to 1. An alternative scaling that is mathematically equivalent is used in ARIB STD-B67 with the source input linear optical intensity having a nominal real-valued range of 0 to 12.

matrix_coeffs describes the matrix coefficients used in deriving luma and chroma signals from the green, blue, and red, or Y, Z, and X primaries, as specified in Table E.5.

matrix_coeffs shall not be equal to 0 unless both of the following conditions are true:

- BitDepth_C is equal to BitDepth_Y.
- chroma_format_idc is equal to 3 (the 4:4:4 chroma format).

The specification of the use of matrix_coeffs equal to 0 under all other conditions is reserved for future use by ITU-T | ISO/IEC.

matrix_coeffs shall not be equal to 8 unless one of the following conditions is true:

- BitDepth_C is equal to BitDepth_Y,
- BitDepth_C is equal to BitDepth_Y + 1 and chroma_format_idc is equal to 3 (the 4:4:4 chroma format).

The specification of the use of matrix_coeffs equal to 8 under all other conditions is reserved for future use by ITU-T | ISO/IEC.

When the matrix_coeffs syntax element is not present, the value of matrix_coeffs is inferred to be equal to 2 (unspecified).

The interpretation of matrix_coeffs, together with colour_primaries and transfer_characteristics, is specified by the equations below.

NOTE 7 – For purposes of YZX representation when matrix_coeffs is equal to 0, the symbols R, G, and B are substituted for X, Y, and Z, respectively, in the following descriptions of Equations E-1 to E-3, E-13 to E-15, E-19 to E-21, and E-31 to E-33.

E_R , E_G , and E_B are defined as "linear-domain" real-valued signals based on the indicated colour primaries before application of the transfer characteristics function.

Nominal peak white is specified as having E_R equal to 1, E_G equal to 1, and E_B equal to 1.

Nominal black is specified as having E_R equal to 0, E_G equal to 0, and E_B equal to 0.

The application of the transfer characteristics function is denoted by $(x)'$ for an argument x .

- If matrix_coeffs is not equal to 14, the signals E'_R , E'_G , and E'_B are determined by application of the transfer characteristics function as follows:

$$E'_R = (E_R)' \quad (E-1)$$

$$E'_G = (E_G)' \quad (E-2)$$

$$E'_B = (E_B)' \quad (E-3)$$

In this case, the range of E'_R , E'_G , and E'_B is specified as follows:

- If transfer_characteristics is equal to 11 or 12, or transfer_characteristics is equal to 13 and matrix_coeffs is not equal to 0, E'_R , E'_G , and E'_B are real numbers with values that have a larger range than the range of 0 to 1, inclusive, and their range is not specified in this Specification.
- Otherwise, E'_R , E'_G and E'_B are real numbers in the range of 0 to 1.
- Otherwise (matrix_coeffs is equal to 14), the "linear-domain" real-valued signals E_L , E_M , and E_S are determined as follows:

$$E_L = (1\,688 * E_R + 2\,146 * E_G + 262 * E_B) \div 4\,096 \quad (E-4)$$

$$E_M = (683 * E_R + 2\,951 * E_G + 462 * E_B) \div 4\,096 \quad (E-5)$$

$$E_S = (99 * E_R + 309 * E_G + 3\,688 * E_B) \div 4\,096 \quad (E-6)$$

In this case, the signals E'_L , E'_M , and E'_S are determined by application of the transfer characteristics function as follows:

$$E'_L = (E_L)' \quad (E-7)$$

$$E'_M = (E_M)' \quad (E-8)$$

$$E'_S = (E_S)' \quad (E-9)$$

The interpretation of `matrix_coeffs` is specified as follows:

- If `video_full_range_flag` is equal to 0, the following applies:

- If `matrix_coeffs` is equal to 1, 4, 5, 6, 7, 9, 10, 11, 12, 13, or 14, the following equations apply:

$$Y = \text{Clip1}_Y(\text{Round}((1 \ll (\text{BitDepth}_Y - 8)) * (219 * E'_Y + 16))) \quad (E-10)$$

$$Cb = \text{Clip1}_C(\text{Round}((1 \ll (\text{BitDepth}_C - 8)) * (224 * E'_{PB} + 128))) \quad (E-11)$$

$$Cr = \text{Clip1}_C(\text{Round}((1 \ll (\text{BitDepth}_C - 8)) * (224 * E'_{PR} + 128))) \quad (E-12)$$

- Otherwise, if `matrix_coeffs` is equal to 0 or 8, the following equations apply:

$$R = \text{Clip1}_Y((1 \ll (\text{BitDepth}_Y - 8)) * (219 * E'_R + 16)) \quad (E-13)$$

$$G = \text{Clip1}_Y((1 \ll (\text{BitDepth}_Y - 8)) * (219 * E'_G + 16)) \quad (E-14)$$

$$B = \text{Clip1}_Y((1 \ll (\text{BitDepth}_Y - 8)) * (219 * E'_B + 16)) \quad (E-15)$$

- Otherwise, if `matrix_coeffs` is equal to 2, the interpretation of the `matrix_coeffs` syntax element is unknown or is determined by the application.
- Otherwise (`matrix_coeffs` is not equal to 0, 1, 2, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, or 14), the interpretation of the `matrix_coeffs` syntax element is reserved for future definition by ITU-T | ISO/IEC.

- Otherwise (`video_full_range_flag` is equal to 1), the following applies:

- If `matrix_coeffs` is equal to 1, 4, 5, 6, 7, 9, 10, 11, 12, 13, or 14, the following applies:

$$Y = \text{Clip1}_Y(\text{Round}(((1 \ll \text{BitDepth}_Y) - 1) * E'_Y)) \quad (E-16)$$

$$Cb = \text{Clip1}_C(\text{Round}(((1 \ll \text{BitDepth}_C) - 1) * E'_{PB} + (1 \ll (\text{BitDepth}_C - 1)))) \quad (E-17)$$

$$Cr = \text{Clip1}_C(\text{Round}(((1 \ll \text{BitDepth}_C) - 1) * E'_{PR} + (1 \ll (\text{BitDepth}_C - 1)))) \quad (E-18)$$

- Otherwise, if `matrix_coeffs` is equal to 0 or 8, the following applies:

$$R = \text{Clip1}_Y(((1 \ll \text{BitDepth}_Y) - 1) * E'_R) \quad (E-19)$$

$$G = \text{Clip1}_Y(((1 \ll \text{BitDepth}_Y) - 1) * E'_G) \quad (E-20)$$

$$B = \text{Clip1}_Y(((1 \ll \text{BitDepth}_Y) - 1) * E'_B) \quad (E-21)$$

- Otherwise, if `matrix_coeffs` is equal to 2, the interpretation of the `matrix_coeffs` syntax element is unknown or is determined by the application.
- Otherwise (`matrix_coeffs` is not equal to 0, 1, 2, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, or 14), the interpretation of the `matrix_coeffs` syntax element is reserved for future definition by ITU-T | ISO/IEC. Reserved values for `matrix_coeffs` shall not be present in bitstreams conforming to this version of this Specification. Decoders shall interpret reserved values of `matrix_coeffs` as equivalent to the value 2.

It is a requirement of bitstream conformance to this version of this Specification that when `colour_primaries` is not equal to 1, 4, 5, 6, 7, 8, 9, 10, 11, 12, or 22, `matrix_coeffs` shall not be equal to 12 or 13.

When `matrix_coeffs` is equal to 1, 4, 5, 6, 7, 9, 10, 11, 12, or 13, the constants K_B and K_R are specified as follows:

- If `matrix_coeffs` is not equal to 12 or 13, the constants K_B and K_R are specified in Table E.5.

- Otherwise (matrix_coeffs is equal to 12 or 13), the constants K_R and K_B are computed as follows, using the chromaticity coordinates (x_R, y_R) , (x_G, y_G) , (x_B, y_B) , and (x_W, y_W) specified by Table E.3 for the colour primaries syntax element for the red, green, blue, and white colour primaries, respectively.

$$K_R = \frac{y_R * (x_W * (y_G * z_B - y_B * z_G) + y_W * (x_B * z_G - x_G * z_B) + z_W * (x_G * y_B - x_B * y_G))}{y_W * (x_R * (y_G * z_B - y_B * z_G) + x_G * (y_B * z_R - y_R * z_B) + x_B * (y_R * z_G - y_G * z_R))} \quad (E-22)$$

$$K_B = \frac{y_B * (x_W * (y_R * z_G - y_G * z_R) + y_W * (x_G * z_R - x_R * z_G) + z_W * (x_R * y_G - x_G * y_R))}{y_W * (x_R * (y_G * z_B - y_B * z_G) + x_G * (y_B * z_R - y_R * z_B) + x_B * (y_R * z_G - y_G * z_R))} \quad (E-23)$$

where the values of z_R , z_G , z_B , and z_W , are given by.

$$z_R = 1 - (x_R + y_R) \quad (E-24)$$

$$z_G = 1 - (x_G + y_G) \quad (E-25)$$

$$z_B = 1 - (x_B + y_B) \quad (E-26)$$

$$z_W = 1 - (x_W + y_W) \quad (E-27)$$

The variables E'_Y , E'_{PB} , and E'_{PR} (for matrix_coeffs not equal to 0 or 8) or Y , C_b , and C_r (for matrix_coeffs equal to 0 or 8) are specified as follows:

- If matrix_coeffs is not equal to 0, 8, 10, 11, 13, or 14, the following equations apply:

$$E'_Y = K_R * E'_R + (1 - K_R - K_B) * E'_G + K_B * E'_B \quad (E-28)$$

$$E'_{PB} = 0.5 * (E'_B - E'_Y) \div (1 - K_B) \quad (E-29)$$

$$E'_{PR} = 0.5 * (E'_R - E'_Y) \div (1 - K_R) \quad (E-30)$$

NOTE 8 – E'_Y is a real number with the value 0 associated with nominal black and the value 1 associated with nominal white. E'_{PB} and E'_{PR} are real numbers with the value 0 associated with both nominal black and nominal white. When transfer_characteristics is not equal to 11 or 12, E'_Y is a real number with values in the range of 0 to 1 inclusive. When transfer_characteristics is not equal to 11 or 12, E'_{PB} and E'_{PR} are real numbers with values in the range of -0.5 to 0.5 inclusive. When transfer_characteristics is equal to 11 or 12, E'_Y , E'_{PB} , and E'_{PR} are real numbers with a larger range not specified in this Specification.

- Otherwise, if matrix_coeffs is equal to 0, the following equations apply:

$$Y = \text{Round}(G) \quad (E-31)$$

$$C_b = \text{Round}(B) \quad (E-32)$$

$$C_r = \text{Round}(R) \quad (E-33)$$

- Otherwise, if matrix_coeffs is equal to 8, the following applies:

- If BitDepth_C is equal to BitDepth_Y, the following equations apply:

$$Y = \text{Round}(0.5 * G + 0.25 * (R + B)) \quad (E-34)$$

$$C_b = \text{Round}(0.5 * G - 0.25 * (R + B)) + (1 \ll (\text{BitDepth}_C - 1)) \quad (E-35)$$

$$C_r = \text{Round}(0.5 * (R - B)) + (1 \ll (\text{BitDepth}_C - 1)) \quad (E-36)$$

NOTE 9 – In this case, for purposes of the YCgCo nomenclature used in Table E.5, C_b and C_r of Equations E-35 and E-36 may be referred to as C_g and C_o , respectively. An appropriate inverse conversion for Equations E-34 to E-36 is as follows:

$$t = Y - (C_b - (1 \ll (\text{BitDepth}_C - 1))) \quad (E-37)$$

$$G = \text{Clip1}_Y(Y + (C_b - (1 \ll (\text{BitDepth}_C - 1)))) \quad (E-38)$$

$$B = \text{Clip1}_Y(t - (C_r - (1 \ll (\text{BitDepth}_C - 1)))) \quad (E-39)$$

$$R = \text{Clip1}_Y(t + (C_r - (1 \ll (\text{BitDepth}_C - 1)))) \quad (E-40)$$

- Otherwise (BitDepth_C is not equal to BitDepth_Y), the following equations apply:

$$Cr = \text{Round}(R) - \text{Round}(B) + (1 \ll (\text{BitDepth}_C - 1)) \quad (\text{E-41})$$

$$t = \text{Round}(B) + ((Cr - (1 \ll (\text{BitDepth}_C - 1))) \gg 1) \quad (\text{E-42})$$

$$Cb = \text{Round}(G) - t + (1 \ll (\text{BitDepth}_C - 1)) \quad (\text{E-43})$$

$$Y = t + ((Cb - (1 \ll (\text{BitDepth}_C - 1))) \gg 1) \quad (\text{E-44})$$

NOTE 10 – In this case, for purposes of the YCgCo nomenclature used in Table E.5, Cb and Cr of Equations E-43 and E-41 may be referred to as Cg and Co, respectively. An appropriate inverse conversion for Equations E-41 to E-44 is as follows:

$$t = Y - ((Cb - (1 \ll (\text{BitDepth}_C - 1))) \gg 1) \quad (\text{E-45})$$

$$G = \text{Clip1}_Y(t + (Cb - (1 \ll (\text{BitDepth}_C - 1)))) \quad (\text{E-46})$$

$$B = \text{Clip1}_Y(t - ((Cr - (1 \ll (\text{BitDepth}_C - 1))) \gg 1)) \quad (\text{E-47})$$

$$R = \text{Clip1}_Y(B + (Cr - (1 \ll (\text{BitDepth}_C - 1)))) \quad (\text{E-48})$$

- Otherwise, if matrix_coeffs is equal to 10 or 13, the signal E'_Y is determined by application of the transfer characteristics function as follows and Equations E-51 to E-54 apply for specification of the signals E'_{PB} and E'_{PR} :

$$E_Y = K_R * E_R + (1 - K_R - K_B) * E_G + K_B * E_B \quad (\text{E-49})$$

$$E'_Y = (E_Y)' \quad (\text{E-50})$$

NOTE 11 – In this case, E_Y is defined from the "linear-domain" signals for E_R , E_G , and E_B , prior to application of the transfer characteristics function, which is then applied to produce the signal E'_Y . E_Y and E'_Y are real values with the value 0 associated with nominal black and the value 1 associated with nominal white.

while the signals E'_{PB} and E'_{PR} are determined as follows:

$$E'_{PB} = (E'_B - E'_Y) \div (2 * N_B) \quad \text{for } -N_B \leq E'_B - E'_Y \leq 0 \quad (\text{E-51})$$

$$E'_{PB} = (E'_B - E'_Y) \div (2 * P_B) \quad \text{for } 0 < E'_B - E'_Y \leq P_B \quad (\text{E-52})$$

$$E'_{PR} = (E'_R - E'_Y) \div (2 * N_R) \quad \text{for } -N_R \leq E'_R - E'_Y \leq 0 \quad (\text{E-53})$$

$$E'_{PR} = (E'_R - E'_Y) \div (2 * P_R) \quad \text{for } 0 < E'_R - E'_Y \leq P_R \quad (\text{E-54})$$

where the constants N_B , P_B , N_R , and P_R are determined by application of the transfer characteristics function to expressions involving the constants K_B and K_R as follows:

$$N_B = (1 - K_B)' \quad (\text{E-55})$$

$$P_B = 1 - (K_B)' \quad (\text{E-56})$$

$$N_R = (1 - K_R)' \quad (\text{E-57})$$

$$P_R = 1 - (K_R)' \quad (\text{E-58})$$

- Otherwise, if matrix_coeffs is equal to 11, the following equations apply:

$$E'_Y = E'_G \quad (\text{E-59})$$

$$E'_{PB} = 0.5 * (0.986\,566 * E'_B - E'_Y) \quad (\text{E-60})$$

$$E'_{PR} = 0.5 * (E'_R - 0.991\,902 * E'_Y) \quad (E-61)$$

NOTE 12 – In this case, for purposes of the Y'D'zD'x nomenclature used in Table E.5, E'PB may be referred to as D'z and E'PR may be referred to as D'x.

- Otherwise (matrix_coefs is equal to 14), the following equations apply:
 - If transfer_characteristics is not equal to 18, the following equations apply:

$$E'_Y = 0.5 * (E'_L + E'_M) \quad (E-62)$$

$$E'_{PB} = (6\,610 * E'_L - 13\,613 * E'_M + 7\,003 * E'_S) \div 4\,096 \quad (E-63)$$

$$E'_{PR} = (17\,933 * E'_L - 17\,390 * E'_M - 543 * E'_S) \div 4\,096 \quad (E-64)$$

- Otherwise, the following equations apply:

$$E'_Y = 0.5 * (E'_L + E'_M) \quad (E-65)$$

$$E'_{PB} = (3\,625 * E'_L - 7\,465 * E'_M + 3\,840 * E'_S) \div 4\,096 \quad (E-66)$$

$$E'_{PR} = (9\,500 * E'_L - 9\,212 * E'_M - 288 * E'_S) \div 4\,096 \quad (E-67)$$

NOTE 13 – In this case, for purposes of the IC_TC_P nomenclature used in Table E.5, E'_Y, E'_{PB}, and E'_{PR} of Equations E-62, E-63, and E-64 or Equations E-65, E-66, and E-67 may be referred to as I, C_T, and C_P, respectively. Equations E-62 to E-64 were designed specifically for use with transfer_characteristics equal to 16 (PQ), and Equations E-65 to E-67 were designed specifically for use with transfer_characteristics equal to 18 (HLG).

chroma_loc_info_present_flag equal to 1 specifies that **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** are present. **chroma_loc_info_present_flag** equal to 0 specifies that **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** are not present.

When **chroma_format_idc** is not equal to 1, **chroma_loc_info_present_flag** should be equal to 0.

chroma_sample_loc_type_top_field and **chroma_sample_loc_type_bottom_field** specify the location of chroma samples as follows:

- If **chroma_format_idc** is equal to 1 (4:2:0 chroma format), **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** specify the location of chroma samples for the top field and the bottom field, respectively, as shown in Figure E.1.
- Otherwise (**chroma_format_idc** is not equal to 1), the values of the syntax elements **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** shall be ignored. When **chroma_format_idc** is equal to 2 (4:2:2 chroma format) or 3 (4:4:4 chroma format), the location of chroma samples is specified in clause 6.2. When **chroma_format_idc** is equal to 0, there is no chroma sample array.

The value of **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** shall be in the range of 0 to 5, inclusive. When the **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** are not present, the values of **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** are inferred to be equal to 0.

NOTE 14 – When coding progressive source material, **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** should have the same value.

Interpretation of symbols

Luma sample position indications:

⊗ Luma sample top field □ Luma sample bottom field

Chroma sample position indications, where gray fill indicates a bottom field sample type and no fill indicates a top field sample type:

○ Chroma sample type 2 ○ Chroma sample type 3
 ○ Chroma sample type 0 ▽ Chroma sample type 1
 ◇ Chroma sample type 4 △ Chroma sample type 5

Figure E.1 – Location of chroma samples for top and bottom fields for **chroma_format_idc equal to 1 (4:2:0 chroma format) as a function of **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field****

Figure E.2 illustrates the indicated relative position of the top-left chroma sample when **chroma_format_idc** is equal to 1 (4:2:0 chroma format), and **chroma_sample_loc_type_top_field** and **chroma_sample_loc_type_bottom_field** are both

equal to the value of a variable ChromaLocType. The region represented by the top-left 4:2:0 chroma sample (depicted as a large red square with a large red dot at its centre) is shown relative to the region represented by the top-left luma sample (depicted as a small black square with a small black dot at its centre). The regions represented by neighbouring luma samples are depicted as small grey squares with small grey dots at their centres.

Figure E.2 – Location of the top-left chroma sample when chroma_format_idc is equal to 1 (4:2:0 chroma format) as a function of ChromaLocType

The relative spatial positioning of the chroma samples, as illustrated in Figure E.3, can be expressed by defining two variables HorizontalOffsetC and VerticalOffsetC as a function of chroma_format_idc and the variable ChromaLocType as given by Table E.6, where HorizontalOffsetC is the horizontal (x) position of the centre of the top-left chroma sample relative to the centre of the top-left luma sample in units of luma samples and VerticalOffsetC is the vertical (y) position of the centre of the top-left chroma sample relative to the centre of the top-left luma sample in units of luma samples.

In a typical FIR filter design, when chroma_format_idc is equal to 1 (4:2:0 chroma format) or 2 (4:2:2 chroma format), HorizontalOffsetC and VerticalOffsetC would serve as the phase offsets for the horizontal and vertical filter operations, respectively, for separable downsampling from 4:4:4 chroma format to the chroma format indicated by chroma_format_idc.

Figure E.3 – Location of the top-left chroma sample when chroma_format_idc is equal to 1 (4:2:0 chroma format) when ChromaLocType is equal to 1

Table E.6 – Definition of HorizontalOffsetC and VerticalOffsetC as a function of chroma_format_idc and ChromaLocType

chroma_format_idc	ChromaLocType	HorizontalOffsetC	VerticalOffsetC
1 (4:2:0)	0	0	0.5
1 (4:2:0)	1	0.5	0.5
1 (4:2:0)	2	0	0
1 (4:2:0)	3	0.5	0
1 (4:2:0)	4	0	1
1 (4:2:0)	5	0.5	1
2 (4:2:2)	–	0	0
3 (4:4:4)	–	0	0

When `chroma_format_idc` is equal to 1 (4:2:0 chroma format) and the decoded video content is intended for interpretation according to Rec. ITU-R BT.2020-2 or Rec. ITU-R BT.2100-2, `chroma_loc_info_present_flag` should be equal to 1, and `chroma_sample_loc_type_top_field` and `chroma_sample_loc_type_bottom_field` should both be equal to 2.

neutral_chroma_indication_flag equal to 1 indicates that the value of all decoded chroma samples is equal to $1 \ll (\text{BitDepth}_C - 1)$. `neutral_chroma_indication_flag` equal to 0 provides no indication of decoded chroma sample values. When `neutral_chroma_indication_flag` is equal to 1, it is a requirement of bitstream conformance that the value of all decoded chroma samples produced by the decoding process shall be equal to $1 \ll (\text{BitDepth}_C - 1)$. When `neutral_chroma_indication_flag` is not present, it is inferred to be equal to 0.

NOTE 15 – When `neutral_chroma_indication_flag` is equal to 1, it is not necessary for the decoder to apply the specified decoding process in order to determine the value of the decoded chroma samples.

field_seq_flag equal to 1 indicates that the CVS conveys pictures that represent fields, and specifies that a picture timing SEI message shall be present in every access unit of the current CVS. `field_seq_flag` equal to 0 indicates that the CVS conveys pictures that represent frames and that a picture timing SEI message may or may not be present in any access unit of the current CVS. When `field_seq_flag` is not present, it is inferred to be equal to 0. When `general_frame_only_constraint_flag` is equal to 1, the value of `field_seq_flag` shall be equal to 0.

NOTE 16 – The specified decoding process does not treat access units conveying pictures that represent fields or frames differently. A sequence of pictures that represent fields would therefore be coded with the picture dimensions of an individual field. For example, access units containing pictures that represent 1080i fields would commonly have cropped output dimensions of 1920x540, while the sequence picture rate would commonly express the rate of the source fields (typically between 50 and 60 Hz), instead of the source frame rate (typically between 25 and 30 Hz).

frame_field_info_present_flag equal to 1 specifies that picture timing SEI messages are present for every picture and include the `pic_struct`, `source_scan_type` and `duplicate_flag` syntax elements. `frame_field_info_present_flag` equal to 0 specifies that the `pic_struct` syntax element is not present in picture timing SEI messages.

When `frame_field_info_present_flag` is present and either or both of the following conditions are true, `frame_field_info_present_flag` shall be equal to 1:

- `field_seq_flag` is equal to 1.
- `general_progressive_source_flag` is equal to 1 and `general_interlaced_source_flag` is equal to 1.

When `frame_field_info_present_flag` is not present, its value is inferred as follows:

- If `general_progressive_source_flag` is equal to 1 and `general_interlaced_source_flag` is equal to 1, `frame_field_info_present_flag` is inferred to be equal to 1.
- Otherwise, `frame_field_info_present_flag` is inferred to be equal to 0.

default_display_window_flag equal to 1 indicates that the default display window parameters follow next in the VUI. `default_display_window_flag` equal to 0 indicates that the default display window parameters are not present. The default display window parameters identify the area that is within the conformance cropping window and that is suggested to be displayed in the absence of any alternative indication (provided within the bitstream or by external means not specified in this Specification) of preferred display characteristics.

def_disp_win_left_offset, **def_disp_win_right_offset**, **def_disp_win_top_offset** and **def_disp_win_bottom_offset** specify the samples of the pictures in the CVS that are within the default display window, in terms of a rectangular region specified in picture coordinates for display. When `default_display_window_flag` is equal to 0, the values of `def_disp_win_left_offset`, `def_disp_win_right_offset`, `def_disp_win_top_offset` and `def_disp_win_bottom_offset` are inferred to be equal to 0.

The following variables are derived from the default display window parameters:

$$\text{leftOffset} = \text{conf_win_left_offset} + \text{def_disp_win_left_offset} \quad (\text{E-68})$$

$$\text{rightOffset} = \text{conf_win_right_offset} + \text{def_disp_win_right_offset} \quad (\text{E-69})$$

$$\text{topOffset} = \text{conf_win_top_offset} + \text{def_disp_win_top_offset} \quad (\text{E-70})$$

$$\text{bottomOffset} = \text{conf_win_bottom_offset} + \text{def_disp_win_bottom_offset} \quad (\text{E-71})$$

The default display window contains the luma samples with horizontal picture coordinates from $\text{SubWidthC} * \text{leftOffset}$ to $\text{pic_width_in_luma_samples} - (\text{SubWidthC} * \text{rightOffset} + 1)$ and vertical picture coordinates from $\text{SubHeightC} * \text{topOffset}$ to $\text{pic_height_in_luma_samples} - (\text{SubHeightC} * \text{bottomOffset} + 1)$, inclusive.

The value of $\text{SubWidthC} * (\text{leftOffset} + \text{rightOffset})$ shall be less than $\text{pic_width_in_luma_samples}$ and the value of $\text{SubHeightC} * (\text{topOffset} + \text{bottomOffset})$ shall be less than $\text{pic_height_in_luma_samples}$.

When ChromaArrayType is not equal to 0, the corresponding specified samples of the two chroma arrays are the samples having picture coordinates $(x / \text{SubWidthC}, y / \text{SubHeightC})$, where (x, y) are the picture coordinates of the specified luma samples.

vui_timing_info_present_flag equal to 1 specifies that **vui_num_units_in_tick**, **vui_time_scale**, **vui_poc_proportional_to_timing_flag** and **vui_hrd_parameters_present_flag** are present in the **vui_parameters()** syntax structure. **vui_timing_info_present_flag** equal to 0 specifies that **vui_num_units_in_tick**, **vui_time_scale**, **vui_poc_proportional_to_timing_flag** and **vui_hrd_parameters_present_flag** are not present in the **vui_parameters()** syntax structure.

vui_num_units_in_tick is the number of time units of a clock operating at the frequency **vui_time_scale** Hz that corresponds to one increment (called a clock tick) of a clock tick counter. **vui_num_units_in_tick** shall be greater than 0. A clock tick, in units of seconds, is equal to the quotient of **vui_num_units_in_tick** divided by **vui_time_scale**. For example, when the picture rate of a video signal is 25 Hz, **vui_time_scale** may be equal to 27 000 000 and **vui_num_units_in_tick** may be equal to 1 080 000 and consequently a clock tick may be equal to 0.04 seconds.

When **vps_num_units_in_tick** is present in the VPS referred to by the SPS, **vui_num_units_in_tick**, when present, shall be equal to **vps_num_units_in_tick**, and when not present, is inferred to be equal to **vps_num_units_in_tick**.

vui_time_scale is the number of time units that pass in one second. For example, a time coordinate system that measures time using a 27 MHz clock has a **vui_time_scale** of 27 000 000. The value of **vui_time_scale** shall be greater than 0.

When **vps_time_scale** is present in the VPS referred to by the SPS, **vui_time_scale**, when present, shall be equal to **vps_time_scale**, and when not present, is inferred to be equal to **vps_time_scale**.

vui_poc_proportional_to_timing_flag equal to 1 indicates that the picture order count value for each picture in the CVS that is not the first picture in the CVS, in decoding order, is proportional to the output time of the picture relative to the output time of the first picture in the CVS. **vui_poc_proportional_to_timing_flag** equal to 0 indicates that the picture order count value for each picture in the CVS that is not the first picture in the CVS, in decoding order, may or may not be proportional to the output time of the picture relative to the output time of the first picture in the CVS.

When **vps_poc_proportional_to_timing_flag** is present in the VPS referred to by the SPS and the value is equal to 1, **vui_poc_proportional_to_timing_flag**, when present, shall be equal to 1.

vui_num_ticks_poc_diff_one_minus1 plus 1 specifies the number of clock ticks corresponding to a difference of picture order count values equal to 1. The value of **vui_num_ticks_poc_diff_one_minus1** shall be in the range of 0 to $2^{32} - 2$, inclusive.

When **vps_num_ticks_poc_diff_one_minus1** is present in the VPS referred to by the SPS, **vui_num_ticks_poc_diff_one_minus1**, when present, shall be equal to **vps_num_ticks_poc_diff_one_minus1**.

vui_hrd_parameters_present_flag equal to 1 specifies that the syntax structure **hrd_parameters()** is present in the **vui_parameters()** syntax structure. **vui_hrd_parameters_present_flag** equal to 0 specifies that the syntax structure **hrd_parameters()** is not present in the **vui_parameters()** syntax structure.

bitstream_restriction_flag equal to 1, specifies that the bitstream restriction parameters for the CVS are present. **bitstream_restriction_flag** equal to 0, specifies that the bitstream restriction parameters for the CVS are not present.

tiles_fixed_structure_flag equal to 1 indicates that each PPS that is active in the CVS has the same value of the syntax elements **num_tile_columns_minus1**, **num_tile_rows_minus1**, **uniform_spacing_flag**, **column_width_minus1[i]**, **row_height_minus1[i]** and **loop_filter_across_tiles_enabled_flag**, when present. **tiles_fixed_structure_flag** equal to 0 indicates that tiles syntax elements in different PPSs may or may not have the same value. When the **tiles_fixed_structure_flag** syntax element is not present, it is inferred to be equal to 0.

NOTE 17 – The signalling of **tiles_fixed_structure_flag** equal to 1 is a guarantee to a decoder that each picture in the CVS has the same number of tiles distributed in the same way which might be useful for workload allocation in the case of multi-threaded decoding.

motion_vectors_over_pic_boundaries_flag equal to 0 indicates that no sample outside the picture boundaries and no sample at a fractional sample position for which the sample value is derived using one or more samples outside the picture boundaries is used for inter prediction of any sample. **motion_vectors_over_pic_boundaries_flag** equal to 1 indicates that one or more samples outside the picture boundaries may be used in inter prediction. When the **motion_vectors_over_pic_boundaries_flag** syntax element is not present, **motion_vectors_over_pic_boundaries_flag** value is inferred to be equal to 1.

restricted_ref_pic_lists_flag equal to 1 indicates that all P and B slices (when present) that belong to the same picture have an identical reference picture list 0 and that all B slices (when present) that belong to the same picture have an identical reference picture list 1.

min_spatial_segmentation_idc, when not equal to 0, establishes a bound on the maximum possible size of distinct coded spatial segmentation regions in the pictures of the CVS. When **min_spatial_segmentation_idc** is not present, it is inferred to be equal to 0. The value of **min_spatial_segmentation_idc** shall be in the range of 0 to 4095, inclusive.

The variable **minSpatialSegmentationTimes4** is derived from **min_spatial_segmentation_idc** as follows:

$$\text{minSpatialSegmentationTimes4} = \text{min_spatial_segmentation_idc} + 4 \quad (\text{E-72})$$

A slice is said to contain a specific luma sample when the coding block that contains the luma sample is contained in the slice. Correspondingly, a tile is said to contain a specific luma sample when the coding block that contains the luma sample is contained in the tile.

Depending on the value of **min_spatial_segmentation_idc**, the following applies:

- If **min_spatial_segmentation_idc** is equal to 0, no limit on the maximum size of spatial segments is indicated.
- Otherwise (**min_spatial_segmentation_idc** is not equal to 0), it is a requirement of bitstream conformance that exactly one of the following conditions shall be true:
 - In each PPS that is activated within the CVS, **tiles_enabled_flag** is equal to 0 and **entropy_coding_sync_enabled_flag** is equal to 0 and there is no slice in the CVS that contains more than $(4 * \text{PicSizeInSamplesY}) / \text{minSpatialSegmentationTimes4}$ luma samples.
 - In each PPS that is activated within the CVS, **tiles_enabled_flag** is equal to 1 and **entropy_coding_sync_enabled_flag** is equal to 0 and there is no tile in the CVS that contains more than $(4 * \text{PicSizeInSamplesY}) / \text{minSpatialSegmentationTimes4}$ luma samples.
 - In each PPS that is activated within the CVS, **tiles_enabled_flag** is equal to 0 and **entropy_coding_sync_enabled_flag** is equal to 1 and the syntax elements **pic_width_in_luma_samples**, **pic_height_in_luma_samples** and the variable **CtbSizeY** obey the following constraint:

$$(2 * \text{pic_height_in_luma_samples} + \text{pic_width_in_luma_samples}) * \text{CtbSizeY} \leq (4 * \text{PicSizeInSamplesY}) / \text{minSpatialSegmentationTimes4} \quad (\text{E-73})$$

NOTE 18 – The syntax element **min_spatial_segmentation_idc** can be used by a decoder to calculate the maximum number of luma samples to be processed by one processing thread, making the assumption that the decoder maximally utilizes the parallel decoding information. However, it is important to be aware that there may be some inter-dependencies between the different threads – e.g., due to entropy coding synchronization or deblocking filtering across tile or slice boundaries. To aid decoders in planning the decoding workload distribution, encoders are encouraged to set the value of **min_spatial_segmentation_idc** to the highest possible value for which one of the above three conditions is true. For example, for the case when **tiles_enabled_flag** is equal to 0 and **entropy_coding_sync_enabled_flag** is equal to 1, encoders should set **min_spatial_segmentation_idc** equal to $4 * \text{PicSizeInSamplesY} / ((2 * \text{pic_height_in_luma_samples} + \text{pic_width_in_luma_samples}) * \text{CtbSizeY}) - 4$.

max_bytes_per_pic_denom indicates a number of bytes not exceeded by the sum of the sizes of the VCL NAL units associated with any coded picture in the CVS.

The number of bytes that represent a picture in the NAL unit stream is specified for this purpose as the total number of bytes of VCL NAL unit data (i.e., the total of the **NumBytesInNalUnit** variables for the VCL NAL units) for the picture. The value of **max_bytes_per_pic_denom** shall be in the range of 0 to 16, inclusive.

Depending on the value of **max_bytes_per_pic_denom** the following applies:

- If **max_bytes_per_pic_denom** is equal to 0, no limits are indicated.
- Otherwise (**max_bytes_per_pic_denom** is not equal to 0), it is a requirement of bitstream conformance that no coded picture shall be represented in the CVS by more than the following number of bytes.

$$(\text{PicSizeInMinCbsY} * \text{RawMinCuBits}) \div (8 * \text{max_bytes_per_pic_denom}) \quad (\text{E-74})$$

When the **max_bytes_per_pic_denom** syntax element is not present, the value of **max_bytes_per_pic_denom** is inferred to be equal to 2.

max_bits_per_min_cu_denom indicates an upper bound for the number of coded bits of **coding_unit()** data for any coding block in any picture of the CVS. The value of **max_bits_per_min_cu_denom** shall be in the range of 0 to 16, inclusive.

Depending on the value of `max_bits_per_min_cu_denom`, the following applies:

- If `max_bits_per_min_cu_denom` is equal to 0, no limit is specified by this syntax element.
- Otherwise (`max_bits_per_min_cu_denom` is not equal to 0), it is a requirement of bitstream conformance that no coded coding_unit() shall be represented in the bitstream by more than the following number of bits:

$$(128 + \text{RawMinCuBits}) \div \text{max_bits_per_min_cu_denom} \\ * (1 \ll (2 * (\log_2 \text{CbSize} - \text{MinCbLog}_2 \text{SizeY}))) \quad (\text{E-75})$$

where `log2CbSize` is the value of `log2CbSize` for the given coding block and the number of bits of coding_unit() data for the same coding block is given by the number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4.

When the `max_bits_per_min_cu_denom` is not present, the value of `max_bits_per_min_cu_denom` is inferred to be equal to 1.

log2_max_mv_length_horizontal and **log2_max_mv_length_vertical** indicate the maximum absolute value of a decoded horizontal and vertical motion vector component, respectively, in quarter luma sample units, for all pictures in the CVS. A value of `n` asserts that no value of a motion vector component is outside the range of -2^n to $2^n - 1$, inclusive, in units of quarter luma sample displacement, where `n` refers to the value of `log2_max_mv_length_horizontal` and `log2_max_mv_length_vertical` for the horizontal and vertical component of the MV, respectively. The values of `log2_max_mv_length_horizontal` and `log2_max_mv_length_vertical` shall be in the range of 0 to 15, inclusive. When not present, the values of `log2_max_mv_length_horizontal` and `log2_max_mv_length_vertical` are both inferred to be equal to 15.

E.3.2 HRD parameters semantics

The `hrd_parameters()` syntax structure provides HRD parameters used in the HRD operations for a layer set. When the `hrd_parameters()` syntax structure is included in a VPS, the applicable layer set to which the `hrd_parameters()` syntax structure applies is specified by the corresponding `hrd_layer_set_idx[i]` syntax element in the VPS. When the `hrd_parameters()` syntax structure is included in an SPS, the layer set to which the `hrd_parameters()` syntax structure applies is the layer set for which the associated layer identifier list contains all `nuh_layer_id` values present in the CVS.

For interpretation of the following semantics, the bitstream (or a part thereof) refers to the bitstream subset (or a part thereof) associated with the layer set to which the `hrd_parameters()` syntax structure applies.

nal_hrd_parameters_present_flag equal to 1 specifies that NAL HRD parameters (pertaining to the Type II bitstream conformance point) are present in the `hrd_parameters()` syntax structure. **nal_hrd_parameters_present_flag** equal to 0 specifies that NAL HRD parameters are not present in the `hrd_parameters()` syntax structure.

NOTE 1 – When `nal_hrd_parameters_present_flag` is equal to 0, the conformance of the bitstream cannot be verified without provision of the NAL HRD parameters and all buffering period SEI messages, and, when `vcl_hrd_parameters_present_flag` is also equal to 0, all picture timing and decoding unit information SEI messages, by some means not specified in this Specification.

The variable `NalHrdBpPresentFlag` is derived as follows:

- If one or more of the following conditions are true, the value of `NalHrdBpPresentFlag` is set equal to 1:
 - `nal_hrd_parameters_present_flag` is present in the bitstream and is equal to 1.
 - The need for the presence of buffering period parameters for NAL HRD operation in the bitstream in buffering period SEI messages is determined by the application, by some means not specified in this Specification.
- Otherwise, the value of `NalHrdBpPresentFlag` is set equal to 0.

vcl_hrd_parameters_present_flag equal to 1 specifies that VCL HRD parameters (pertaining to the Type I bitstream conformance point) are present in the `hrd_parameters()` syntax structure. **vcl_hrd_parameters_present_flag** equal to 0 specifies that VCL HRD parameters are not present in the `hrd_parameters()` syntax structure.

NOTE 2 – When `vcl_hrd_parameters_present_flag` is equal to 0, the conformance of the bitstream cannot be verified without provision of the VCL HRD parameters and all buffering period SEI messages, and, when `nal_hrd_parameters_present_flag` is also equal to 0, all picture timing and decoding unit information SEI messages, by some means not specified in this Specification.

The variable `VclHrdBpPresentFlag` is derived as follows:

- If one or more of the following conditions are true, the value of `VclHrdBpPresentFlag` is set equal to 1:
 - `vcl_hrd_parameters_present_flag` is present in the bitstream and is equal to 1.
 - The need for the presence of buffering period parameters for VCL HRD operation in the bitstream in buffering period SEI messages is determined by the application, by some means not specified in this Specification.
- Otherwise, the value of `VclHrdBpPresentFlag` is set equal to 0.

The variable CpbDpbDelaysPresentFlag is derived as follows:

- If one or more of the following conditions are true, the value of CpbDpbDelaysPresentFlag is set equal to 1:
 - nal_hrd_parameters_present_flag is present in the bitstream and is equal to 1.
 - vcl_hrd_parameters_present_flag is present in the bitstream and is equal to 1.
 - The need for presence of CPB and DPB output delays to be present in the bitstream in picture timing SEI messages is determined by the application, by some means not specified in this Specification.
- Otherwise, the value of CpbDpbDelaysPresentFlag is set equal to 0.

When NalHrdBpPresentFlag and VclHrdBpPresentFlag are both equal to 0, the value of CpbDpbDelaysPresentFlag shall be equal to 0.

sub_pic_hrd_params_present_flag equal to 1 specifies that sub-picture level HRD parameters are present and the HRD may operate at access unit level or sub-picture level. **sub_pic_hrd_params_present_flag** equal to 0 specifies that sub-picture level HRD parameters are not present and the HRD operates at access unit level. When **sub_pic_hrd_params_present_flag** is not present, its value is inferred to be equal to 0.

tick_divisor_minus2 is used to specify the clock sub-tick. A clock sub-tick is the minimum interval of time that can be represented in the coded data when **sub_pic_hrd_params_present_flag** is equal to 1.

du_cpb_removal_delay_increment_length_minus1 plus 1 specifies the length, in bits, of the **du_cpb_removal_delay_increment_minus1[i]** and **du_common_cpb_removal_delay_increment_minus1** syntax elements of the picture timing SEI message and the **du_spt_cpb_removal_delay_increment** syntax element in the decoding unit information SEI message.

sub_pic_cpb_params_in_pic_timing_sei_flag equal to 1 specifies that sub-picture level CPB removal delay parameters are present in picture timing SEI messages and no decoding unit information SEI message is available (in the CVS or provided through external means not specified in this Specification). **sub_pic_cpb_params_in_pic_timing_sei_flag** equal to 0 specifies that sub-picture level CPB removal delay parameters are present in decoding unit information SEI messages and picture timing SEI messages do not include sub-picture level CPB removal delay parameters. When the **sub_pic_cpb_params_in_pic_timing_sei_flag** syntax element is not present, it is inferred to be equal to 0.

dpb_output_delay_du_length_minus1 plus 1 specifies the length, in bits, of the **pic_dpb_output_du_delay** syntax element in the picture timing SEI message and the **pic_spt_dpb_output_du_delay** syntax element in the decoding unit information SEI message.

bit_rate_scale (together with **bit_rate_value_minus1[i]**) specifies the maximum input bit rate of the i-th CPB.

cpb_size_scale (together with **cpb_size_value_minus1[i]**) specifies the CPB size of the i-th CPB when the CPB operates at the access unit level.

cpb_size_du_scale (together with **cpb_size_du_value_minus1[i]**) specifies the CPB size of the i-th CPB when the CPB operates at sub-picture level.

initial_cpb_removal_delay_length_minus1 plus 1 specifies the length, in bits, of the **nal_initial_cpb_removal_delay[i]**, **nal_initial_cpb_removal_offset[i]**, **vcl_initial_cpb_removal_delay[i]** and **vcl_initial_cpb_removal_offset[i]** syntax elements of the buffering period SEI message. When the **initial_cpb_removal_delay_length_minus1** syntax element is not present, it is inferred to be equal to 23.

au_cpb_removal_delay_length_minus1 plus 1 specifies the length, in bits, of the **cpb_delay_offset** syntax element in the buffering period SEI message and the **au_cpb_removal_delay_minus1** syntax element in the picture timing SEI message. When the **au_cpb_removal_delay_length_minus1** syntax element is not present, it is inferred to be equal to 23.

dpb_output_delay_length_minus1 plus 1 specifies the length, in bits, of the **dpb_delay_offset** syntax element in the buffering period SEI message and the **pic_dpb_output_delay** syntax element in the picture timing SEI message. When the **dpb_output_delay_length_minus1** syntax element is not present, it is inferred to be equal to 23.

fixed_pic_rate_general_flag[i] equal to 1 indicates that, when HighestTid is equal to i, the temporal distance between the HRD output times of consecutive pictures in output order is constrained as specified below. **fixed_pic_rate_general_flag[i]** equal to 0 indicates that this constraint may not apply.

When **fixed_pic_rate_general_flag[i]** is not present, it is inferred to be equal to 0.

fixed_pic_rate_within_cvs_flag[i] equal to 1 indicates that, when HighestTid is equal to i, the temporal distance between the HRD output times of consecutive pictures in output order is constrained as specified below. **fixed_pic_rate_within_cvs_flag[i]** equal to 0 indicates that this constraint may not apply.

When `fixed_pic_rate_general_flag[i]` is equal to 1, the value of `fixed_pic_rate_within_cvs_flag[i]` is inferred to be equal to 1.

elemental_duration_in_tc_minus1[i] plus 1 (when present) specifies, when `HighestTid` is equal to `i`, the temporal distance, in clock ticks, between the elemental units that specify the HRD output times of consecutive pictures in output order as specified below. The value of `elemental_duration_in_tc_minus1[i]` shall be in the range of 0 to 2 047, inclusive.

For each picture `n` that is output and not the last picture in the bitstream (in output order) that is output, the value of the variable `DpbOutputElementalInterval[n]` is specified by:

$$\text{DpbOutputElementalInterval}[n] = \text{DpbOutputInterval}[n] \div \text{DeltaToDivisor} \quad (\text{E-76})$$

where `DpbOutputInterval[n]` is specified in Equation C-16 and `DeltaToDivisor` is specified in Table E.7 based on the value of `frame_field_info_present_flag` and `pic_struct` for the CVS containing picture `n`. Entries marked "-" in Table E.7 indicate a lack of dependence of `DeltaToDivisor` on the corresponding syntax element.

When `HighestTid` is equal to `i` and `fixed_pic_rate_general_flag[i]` is equal to 1 for a CVS containing picture `n`, the value computed for `DpbOutputElementalInterval[n]` shall be equal to `ClockTick * (elemental_duration_in_tc_minus1[i] + 1)`, wherein `ClockTick` is as specified in Equation C-1 (using the value of `ClockTick` for the CVS containing picture `n`) when one of the following conditions is true for the following picture in output order `nextPicInOutputOrder` that is specified for use in Equation C-16:

- picture `nextPicInOutputOrder` is in the same CVS as picture `n`.
- picture `nextPicInOutputOrder` is in a different CVS and `fixed_pic_rate_general_flag[i]` is equal to 1 in the CVS containing picture `nextPicInOutputOrder`, the value of `ClockTick` is the same for both CVSs and the value of `elemental_duration_in_tc_minus1[i]` is the same for both CVSs.

When `HighestTid` is equal to `i` and `fixed_pic_rate_within_cvs_flag[i]` is equal to 1 for a CVS containing picture `n`, the value computed for `DpbOutputElementalInterval[n]` shall be equal to `ClockTick * (elemental_duration_in_tc_minus1[i] + 1)`, wherein `ClockTick` is as specified in Equation C-1 (using the value of `ClockTick` for the CVS containing picture `n`) when the following picture in output order `nextPicInOutputOrder` that is specified for use in Equation C-16 is in the same CVS as picture `n`.

Table E.7 – Divisor for computation of `DpbOutputElementalInterval[n]`

frame_field_info_present_flag	pic_struct	DeltaToDivisor
0	-	1
1	1	1
1	2	1
1	0	1
1	3	2
1	4	2
1	5	3
1	6	3
1	7	2
1	8	3
1	9	1
1	10	1
1	11	1
1	12	1

low_delay_hrd_flag[i] specifies the HRD operational mode, when `HighestTid` is equal to `i`, as specified in Annex C or clause F.13. When not present, the value of `low_delay_hrd_flag[i]` is inferred to be equal to 0.

NOTE 3 – When `low_delay_hrd_flag[i]` is equal to 1, "big pictures" that violate the nominal CPB removal times due to the number of bits used by an access unit are permitted. It is expected, but not required, that such "big pictures" occur only occasionally.

cpb_cnt_minus1[i] plus 1 specifies the number of alternative CPB specifications in the bitstream of the CVS when `HighestTid` is equal to `i`. The value of `cpb_cnt_minus1[i]` shall be in the range of 0 to 31, inclusive. When not present, the value of `cpb_cnt_minus1[i]` is inferred to be equal to 0.

E.3.3 Sub-layer HRD parameters semantics

The variable CpbCnt is set equal to `cpb_cnt_minus1[subLayerId] + 1`.

bit_rate_value_minus1[i] (together with `bit_rate_scale`) specifies the maximum input bit rate for the *i*-th CPB when the CPB operates at the access unit level. `bit_rate_value_minus1[i]` shall be in the range of 0 to $2^{32} - 2$, inclusive. For any *i* > 0, `bit_rate_value_minus1[i]` shall be greater than `bit_rate_value_minus1[i - 1]`.

When `SubPicHrdFlag` is equal to 0, the bit rate in bits per second is given by:

$$\text{BitRate}[i] = (\text{bit_rate_value_minus1}[i] + 1) * 2^{(6 + \text{bit_rate_scale})} \quad (\text{E-77})$$

When `SubPicHrdFlag` is equal to 0 and the `bit_rate_value_minus1[i]` syntax element is not present, the value of `BitRate[i]` is inferred to be equal to `BrVclFactor * MaxBR` for VCL HRD parameters and to be equal to `BrNalFactor * MaxBR` for NAL HRD parameters, where `MaxBR`, `BrVclFactor` and `BrNalFactor` are specified in clause A.4.

cpb_size_value_minus1[i] is used together with `cpb_size_scale` to specify the *i*-th CPB size when the CPB operates at the access unit level. `cpb_size_value_minus1[i]` shall be in the range of 0 to $2^{32} - 2$, inclusive. For any *i* greater than 0, `cpb_size_value_minus1[i]` shall be less than or equal to `cpb_size_value_minus1[i - 1]`.

When `SubPicHrdFlag` is equal to 0, the CPB size in bits is given by:

$$\text{CpbSize}[i] = (\text{cpb_size_value_minus1}[i] + 1) * 2^{(4 + \text{cpb_size_scale})} \quad (\text{E-78})$$

When `SubPicHrdFlag` is equal to 0 and the `cpb_size_value_minus1[i]` syntax element is not present, the value of `CpbSize[i]` is inferred to be equal to `CpbVclFactor * MaxCPB` for VCL HRD parameters and to be equal to `CpbNalFactor * MaxCPB` for NAL HRD parameters, where `MaxCPB`, `CpbVclFactor` and `CpbNalFactor` are specified in clause A.4.

cpb_size_du_value_minus1[i] is used together with `cpb_size_du_scale` to specify the *i*-th CPB size when the CPB operates at sub-picture level. `cpb_size_du_value_minus1[i]` shall be in the range of 0 to $2^{32} - 2$, inclusive. For any *i* greater than 0, `cpb_size_du_value_minus1[i]` shall be less than or equal to `cpb_size_du_value_minus1[i - 1]`.

When `SubPicHrdFlag` is equal to 1, the CPB size in bits is given by:

$$\text{CpbSize}[i] = (\text{cpb_size_du_value_minus1}[i] + 1) * 2^{(4 + \text{cpb_size_du_scale})} \quad (\text{E-79})$$

When `SubPicHrdFlag` is equal to 1 and the `cpb_size_du_value_minus1[i]` syntax element is not present, the value of `CpbSize[i]` is inferred to be equal to `CpbVclFactor * MaxCPB` for VCL HRD parameters and to be equal to `CpbNalFactor * MaxCPB` for NAL HRD parameters, where `MaxCPB`, `CpbVclFactor` and `CpbNalFactor` are specified in clause A.4.

bit_rate_du_value_minus1[i] (together with `bit_rate_scale`) specifies the maximum input bit rate for the *i*-th CPB when the CPB operates at the sub-picture level. `bit_rate_du_value_minus1[i]` shall be in the range of 0 to $2^{32} - 2$, inclusive. For any *i* > 0, `bit_rate_du_value_minus1[i]` shall be greater than `bit_rate_du_value_minus1[i - 1]`.

When `SubPicHrdFlag` is equal to 1, the bit rate in bits per second is given by:

$$\text{BitRate}[i] = (\text{bit_rate_du_value_minus1}[i] + 1) * 2^{(6 + \text{bit_rate_scale})} \quad (\text{E-80})$$

When `SubPicHrdFlag` is equal to 1 and the `bit_rate_du_value_minus1[i]` syntax element is not present, the value of `BitRate[i]` is inferred to be equal to `BrVclFactor * MaxBR` for VCL HRD parameters and to be equal to `BrNalFactor * MaxBR` for NAL HRD parameters, where `MaxBR`, `BrVclFactor` and `BrNalFactor` are specified in clause A.4.

cbr_flag[i] equal to 0 specifies that to decode this CVS by the HRD using the *i*-th CPB specification, the hypothetical stream scheduler (HSS) operates in an intermittent bit rate mode. `cbr_flag[i]` equal to 1 specifies that the HSS operates in a constant bit rate (CBR) mode. When not present, the value of `cbr_flag[i]` is inferred to be equal to 0.

Annex F

Common specifications for multi-layer extensions

(This annex forms an integral part of this Recommendation | International Standard.)

F.1 Scope

This annex specifies the common syntax, semantics and decoding processes for multi-layer video coding extensions, with references made to clauses 2-9 and Annexes A-E, G and H.

F.2 Normative references

The list of normative references in clause 2 applies.

F.3 Definitions

For the purpose of this annex, the following definitions apply in addition to the definitions in clause 3. These definitions are either not present in clause 3 or replace definitions in clause 3.

- F.3.1 access unit:** A set of *NAL units* that are associated with each other according to a specified classification rule, are consecutive in *decoding order* and contain at most one *coded picture* with any specific value of *nuh_layer_id*.
- F.3.2 additional layer set:** A set of *layers* of a *bitstream* with a set of *layers* of one or more *non-base layer subtrees*.
- F.3.3 alternative output layer:** A *layer* that is a *reference layer* of an *output layer* and which may include a *picture* that may be output when no *picture* of the *output layer* is present in the *access unit* containing the *picture*.
- F.3.4 associated IRAP picture:** The previous *IRAP picture* in *decoding order* within the same *layer* (if present).
- F.3.5 auxiliary picture:** A *picture* that has no normative effect on the *decoding process* of *primary pictures* and with a *nuh_layer_id* value such that *AuxId[nuh_layer_id]* is greater than 0.
- F.3.6 auxiliary picture layer:** A *layer* with a *nuh_layer_id* value such that *AuxId[nuh_layer_id]* is greater than 0.
- F.3.7 base bitstream partition:** A *bitstream partition* that contains the *layer* with *nuh_layer_id* equal to *SmallestLayerId*.
- F.3.8 bitstream partition:** A sequence of bits, in the form of a *NAL unit stream* or a *byte stream*, that is a subset of a *bitstream* according to a *partitioning scheme*.
- F.3.9 broken link access (BLA) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to *SmallestLayerId* is a *BLA picture*.
- F.3.10 clean random access (CRA) access unit:** An *access unit* in which the *coded picture* with *nuh_layer_id* equal to *SmallestLayerId* is a *CRA picture*.
- F.3.11 coded layer-wise video sequence (CLVS):** A sequence of *coded pictures*, with the same *nuh_layer_id* value *nuhLayerId*, that consists, in decoding order, of an *IRAP picture* with *NoRaslOutputFlag* equal to 1 or a *picture* with *FirstPicInLayerDecodedFlag[nuhLayerId]* equal to 0, followed by all *coded pictures*, if any, up to but excluding the next *IRAP picture* with *NoRaslOutputFlag* equal to 1 or the next *picture* with *FirstPicInLayerDecodedFlag[nuhLayerId]* equal to 0.
- F.3.12 coded picture:** A *coded representation* of a *picture* comprising *VCL NAL units* with a particular value of *nuh_layer_id* within an *access unit* and containing all *CTUs* of the *picture*.
- F.3.13 coded picture buffer (CPB):** A first-in first-out buffer containing *decoding units* in *decoding order* specified in the *hypothetical reference decoder* in Annex C or in clause F.13.
- F.3.14 coded video sequence (CVS):** A sequence of *access units* that consists, in decoding order, of an *initial IRAP access unit*, followed by zero or more *access units* that are not *initial IRAP access units*, including all subsequent *access units* up to but not including any subsequent *access unit* that is an *initial IRAP access unit*.
- F.3.15 collocated sample:** A reference picture sample located at a corresponding position to the current sample as determined through the resampling process, for use in *inter-layer prediction*.
- F.3.16 cross-layer random access skip (CL-RAS) picture:** A *picture* with *nuh_layer_id* equal to *layerId* such that *LayerInitializedFlag[layerId]* is equal to 0 when the decoding process for starting the decoding of a coded picture with *nuh_layer_id* greater than 0 is invoked.

- F.3.17 decoded picture buffer (DPB):** A buffer holding *decoded pictures* for reference, output reordering, or output delay specified for the *hypothetical reference decoder* in Annex C or in clause F.13.
- F.3.18 decoding unit:** A *partition unit* if SubPicHrdFlag is equal to 0 or a subset of a *partition unit* otherwise, consisting of one or more *VCL NAL units* in a *partition unit* and the *associated non-VCL NAL units*.
- F.3.19 direct predicted layer:** A *layer* for which another *layer* is a *direct reference layer*.
- F.3.20 direct reference layer:** A *layer* that may be used for *inter-layer prediction* of another *layer*.
- F.3.21 direct reference layer picture:** A *picture* in a *direct reference layer* that is used as input to derive an *inter-layer reference picture* for *inter-layer prediction* of the current *picture* and is in the same *access unit* as the current *picture*.
- F.3.22 independent layer:** A *layer* that does not have *direct reference layers*.
- F.3.23 indirect predicted layer:** A *layer* for which another *layer* is an *indirect reference layer*.
- F.3.24 indirect reference layer:** A *layer* that is not a *direct reference layer* of a second *layer* but is a *direct reference layer* of a third *layer* that is a *reference layer* of the second *layer*.
- F.3.25 initial intra random access point (IRAP) access unit:** An *IRAP access unit* in which the *coded picture* with nuh_layer_id equal to SmallestLayerId has NoRaslOutputFlag equal to 1.
- F.3.26 inter-layer prediction:** A *prediction* in a manner that is dependent on data elements (e.g., sample values or motion vectors) of *reference pictures* with a different value of nuh_layer_id than that of the current *picture*.
- F.3.27 inter-layer reference picture:** A *reference picture* that may be used for *inter-layer prediction* of the current *picture* and is in the same *access unit* as the current *picture*.
- F.3.28 intra random access point (IRAP) access unit:** An *access unit* in which the *coded picture* with nuh_layer_id equal to SmallestLayerId is an *IRAP picture*.
- F.3.29 intra random access point (IRAP) picture:** A *coded picture* for which each *VCL NAL unit* has nal_unit_type in the range of BLA_W_LP to RSV_IRAP_VCL23, inclusive.
- NOTE – An IRAP picture belonging to an independent layer contains only I slices. An IRAP picture belonging to a predicted layer with nuh_layer_id value currLayerId may contain P, B and I slices, cannot use inter prediction from other pictures with nuh_layer_id equal to currLayerId and may use inter-layer prediction from its direct reference layers. The IRAP picture belonging to a predicted layer with nuh_layer_id value currLayerId and all subsequent non-RASL pictures with nuh_layer_id equal to currLayerId in decoding order can be correctly decoded without performing the decoding process of any pictures with nuh_layer_id equal to currLayerId that precede the IRAP picture in decoding order, when the necessary parameter sets are available when they need to be activated and LayerInitializedFlag[refLayerId] is equal to 1 for refLayerId equal to all nuh_layer_id values of the direct reference layers of the layer with nuh_layer_id equal to currLayerId.
- F.3.30 layer subtree:** A subset of the *layers* of a *layer tree* including all the *reference layers* of the *layers* within the subset.
- F.3.31 layer tree:** A set of *layers* such that each *layer* in the set of *layers* is a *predicted layer* or a *reference layer* of at least one other *layer* in the set of *layers* and no *layer* outside the set of *layers* is a *predicted layer* or a *reference layer* of any *layer* in the set of *layers*.
- F.3.32 leading picture:** A *picture* that is in the same *layer* as the *associated IRAP picture* and precedes the *associated IRAP picture* in *output order*.
- F.3.33 necessary layer:** A *layer* in an *output operation point* associated with an *OLS*, the *layer* being an *output layer* of the *OLS*, or a *reference layer* of an *output layer* of the *OLS*.
- F.3.34 non-base layer:** A *layer* in which all *VCL NAL units* have the same nuh_layer_id value greater than 0.
- F.3.35 non-base layer subtree:** A *layer subtree* that does not include the *base layer*.
- F.3.36 output layer:** A *layer* of an *output layer set* that is output when TargetOlsIdx is equal to the index of the *output layer set*.
- F.3.37 output layer set (OLS):** A set of *layers* consisting of the *layers* of one of the specified *layer sets*, where one or more *layers* in the set of *layers* are indicated to be *output layers*.
- F.3.38 output operation point:** A *bitstream* that is created from an input *bitstream* by operation of the *sub-bitstream extraction process* with the input *bitstream*, a target highest TemporalId and a target layer identifier list as inputs, and that is associated with a set of *output layers*.

- F.3.39 output order:** The order in which the *decoded pictures* are output from the *decoded picture buffer* (for the *decoded pictures* that are to be output from the *decoded picture buffer*), or the order in which the *access units* are considered to be output from the *decoded picture buffer* (for the *access units* the decoding of which results into *decoded pictures* that are to be output from the *decoded picture buffer*).
- F.3.40 partitioning scheme:** A *partitioning* of *layers* in an *OLS* into one or more *bitstream partitions* such that each *layer* in the *OLS* is included in exactly one *bitstream partition* of the partitioning scheme and each *bitstream partition* of the partitioning scheme contains one or more *layers*.
- F.3.41 partition unit:** A subset of *access unit* consisting of the *picture units* of the *layers* in a *bitstream partition*.
- F.3.42 picture order count (POC):** A variable that is associated with each *picture* and that, at any moment, uniquely identifies the associated *picture* among all *pictures* with the same value of *nuh_layer_id* in the *CVS*, and, when the associated *picture* is to be output from the *decoded picture buffer*, indicates the position of the associated *picture* in *output order* relative to the *output order* positions of the other *pictures* with the same value of *nuh_layer_id* in the same *CVS* that are to be output from the *decoded picture buffer*.
- F.3.43 picture order count (POC) resetting period:** A sequence of *access units* in *decoding order*, starting with an *access unit* with *poc_reset_idc* equal to 1 or 2 and a particular value of *poc_reset_period_id* and including all *access units* that either have the same value of *poc_reset_period_id* or have *poc_reset_idc* equal to 0.
- F.3.44 picture order count (POC) resetting picture:** A *picture* that is the first *picture*, in *decoding order*, of a *layer* of a *POC resetting period*.
- F.3.45 predicted layer:** A *layer* that is a *direct predicted layer* or an *indirect predicted layer* of another *layer*.
- F.3.46 primary picture:** A *picture* with *nuh_layer_id* value such that *AuxId[nuh_layer_id]* is equal to 0.
- F.3.47 primary picture layer:** A *layer* with a *nuh_layer_id* value such that *AuxId[nuh_layer_id]* is equal to 0.
- F.3.48 quality scalability:** A type of scalability, represented by a scalability dimension, that indicates that the *coded pictures* in all *layers* of a *bitstream* have the same values of *luma* width, *luma* height, *chroma* width and *chroma* height, but may have different fidelity level or different values of *luma* or *chroma* bit depths.
- F.3.49 reference layer:** A *layer* that is a *direct reference layer* or an *indirect reference layer* of another *layer*.
- F.3.50 reference picture list:** A list of *reference pictures* that is used for *inter prediction* or *inter-layer prediction* of a *P* or *B slice*.
- F.3.51 scalability dimension:** An indication of the type of *non-base layers* which may be present in a *CVS*.
- F.3.52 source picture for inter-layer prediction:** A *decoded picture* that either is, or is used in deriving, an *inter-layer reference picture* that is included in an *inter-layer reference picture set* of the current *picture*.
- F.3.53 spatial scalability:** A type of scalability, represented by a scalability dimension, that indicates that the *coded pictures* in different *layers* of a *bitstream* have different values of *luma* or *chroma* width or height.
- F.3.54 sub-bitstream extraction process:** A specified process by which *NAL units* in a *bitstream* that do not belong to a target set, determined by a target highest *TemporalId* and a target *layer identifier list*, are removed from the *bitstream*, with the output sub-bitstream consisting of the *NAL units* in the *bitstream* that belong to the target set.
- NOTE – Depending on whether the target layer identifier list includes *nuh_layer_id* equal to 0 and on the value of *vps_base_layer_internal_flag*, the sub-bitstream extraction process may refer to the process specified in clause 10, clause F.10.1 or clause F.10.3.
- F.3.55 target output layer set:** The *output layer set* for which the index is equal to *TargetOlsIdx*.
- F.3.56 trailing picture:** A *picture* that is in the same *layer* as the associated *IRAP picture* and follows the associated *IRAP picture* in *output order*.
- F.3.57 view:** A sequence of *pictures* associated with the same value of *ViewOrderIdx*.
- NOTE – A view typically represents a sequence of pictures captured by one camera.

F.4 Abbreviations

For the purpose of this annex, the following abbreviations apply in addition to the abbreviations in clause 4:

BPB	Bitstream Partition Buffer
HBPS	Hypothetical Bitstream Partition Scheduler
OLS	Output Layer Set

F.5 Conventions

The specifications in clause 5 and its subclauses apply.

F.6 Bitstream and picture formats, partitionings, scanning processes and neighbouring relationships

The specifications in clause 6 and its subclauses apply.

F.7 Syntax and semantics

F.7.1 Method of specifying syntax in tabular form

The specifications in clause 7.1 apply.

F.7.2 Specification of syntax functions, categories and descriptors

The specifications in clause 7.2 apply, with the following additions:

more_data_in_slice_segment_header_extension() is specified as follows:

- If (the current position in the slice_segment_header() syntax structure) – (the position immediately following slice_segment_header_extension_length) is less than (slice_segment_header_extension_length * 8), the return value of more_data_in_slice_segment_header_extension() is equal to TRUE.
- Otherwise, the return value of more_data_in_slice_segment_header_extension() is equal to FALSE.

F.7.3 Syntax in tabular form

F.7.3.1 NAL unit syntax

F.7.3.1.1 General NAL unit syntax

The specifications in clause 7.3.1.1 apply.

F.7.3.1.2 NAL unit header syntax

The specifications in clause 7.3.1.2 apply.

F.7.3.2 Raw byte sequence payloads and RBSP trailing bits syntax

F.7.4 Semantics

F.7.4.1 General

F.7.4.2 NAL unit semantics

F.7.4.2.1 General NAL unit semantics

The specifications in clause 7.4.2.1 apply.

F.7.4.2.2 NAL unit header semantics

The specifications in clause 7.4.2.2 apply with the replacement of references to Annex C with references to clause F.13 and with the following additions:

The variable CraOrBlaPicFlag is derived as follows:

$$\text{CraOrBlaPicFlag} = (\text{nal_unit_type} == \text{BLA_W_LP} \mid \mid \text{nal_unit_type} == \text{BLA_N_LP} \mid \mid \text{nal_unit_type} == \text{BLA_W_RADL} \mid \mid \text{nal_unit_type} == \text{CRA_NUT}) \quad (\text{F-1})$$

NOTE 1 – When a picture picA that is a CRA picture and belongs to a layer with nuh_layer_id equal to layerId is present in a bitstream and pictures belonging to the layer with nuh_layer_id equal to layerId and preceding, in decoding order, the picture picA are dropped due to layer down-switching followed by layer up-switching, the RASL pictures associated with the picture picA, if any, may have some reference pictures that may not be available for reference unless one of the following conditions is true:

- The access unit auA containing the picture picA is an IRAP access unit, and the picture with nuh_layer_id equal to SmallestLayerId in the access unit auA, if any, has NoCrasOutputFlag equal to 1.
- The value of HandleCraAsBlaFlag is equal to 1 for the CRA picture picA.

A NAL unit with nal_unit_type equal to EOS_NUT and with a particular nuh_layer_id value shall not be present in an access unit, unless a coded picture with that particular nuh_layer_id value is present in the same access unit.

NOTE 2 – Let indepLayerId be nuh_layer_id value of any independent non-base layer with nuh_layer_id greater than SmallestLayerId. Let firstPic be the first picture, in decoding order, among the pictures with nuh_layer_id equal to indepLayerId or IdPredictedLayer[indepLayerId][i] for any value of i in the range of 0 to NumPredictedLayers[indepLayerId] – 1, inclusive, that follows an IRAP picture with NoCrasOutputFlag equal to 1. firstPic has to be an IRAP picture with nuh_layer_id equal to indepLayerId and with LayerResetFlag equal to 1.

When nal_unit_type is equal to AUD_NUT, the value of nuh_layer_id shall be equal to the minimum of the nuh_layer_id values of all VCL NAL units in the access unit.

F.7.4.2.3 Encapsulation of an SODB within an RBSP (informative)

The specifications in clause 7.4.2.3 apply.

F.7.4.2.4 Order of NAL units and association to coded pictures, access units and coded video sequences

F.7.4.2.4.1 General

The specifications in clause 7.4.2.4.1 apply.

F.7.4.2.4.2 Order of VPS, SPS and PPS RBSPs and their activation

The specifications in clause 7.4.2.4.2 apply with the following additions:

A PPS RBSP includes parameters that can be referred to by the coded slice segment NAL units of one or more coded pictures. Each PPS RBSP is initially considered not active for any layer at the start of the operation of the decoding process. At most one PPS RBSP is considered active for each layer at any given moment during the operation of the decoding process and the activation of any particular PPS RBSP for a particular layer results in the deactivation of the previously-active PPS RBSP for the particular layer (if any).

One PPS RBSP may be the active PPS RBSP for more than one layer. When not explicitly specified, the layer a PPS RBSP is active for is inferred to be the current layer in the context where the active PPS RBSP is referred to.

When a PPS RBSP (with a particular value of pps_pic_parameter_set_id) is not active for a particular layer with nuh_layer_id activatingLayerId and it is referred to by a coded slice segment NAL unit (using a value of slice_pic_parameter_set_id equal to the pps_pic_parameter_set_id value) of the particular layer, it is activated for the particular layer. This PPS RBSP is called the active PPS RBSP for the particular layer until it is deactivated by the activation of another PPS RBSP for the particular layer. A PPS RBSP, with that particular value of pps_pic_parameter_set_id, shall be available to the decoding process prior to its activation, included in at least one access unit with TemporalId less than or equal to the TemporalId of the PPS NAL unit or provided through external means, and the PPS NAL unit containing the PPS RBSP shall have nuh_layer_id equal to 0, activatingLayerId, or IdRefLayer[activatingLayerId][i] with any value of i in the range of 0 to NumRefLayers[activatingLayerId] – 1, inclusive.

NOTE 1 – All PPSs, regardless of their values of nuh_layer_id or TemporalId, share the same value space for pps_pic_parameter_set_id. In other words, a PPS with nuh_layer_id equal to X, TemporalId equal to Y and pps_pic_parameter_set_id equal to A would update the previously received PPS that has pps_pic_parameter_set_id equal to A and that has nuh_layer_id not equal to X or TemporalId not equal to Y.

An SPS RBSP includes parameters that can be referred to by one or more PPS RBSPs or one or more SEI NAL units containing an active parameter sets SEI message. Each SPS RBSP is initially considered not active for any layer at the start of the operation of the decoding process. At most one SPS RBSP is considered active for each layer at any given moment during the operation of the decoding process and the activation of any particular SPS RBSP for a particular layer results in the deactivation of the previously-active SPS RBSP for that particular layer (if any).

One SPS RBSP may be the active SPS RBSP for more than one layer. When not explicitly specified, the layer an SPS RBSP is active for is inferred to be the current layer in the context where the active SPS RBSP is referred to.

When an SPS RBSP (with a particular value of `sps_seq_parameter_set_id`) is not already active for a particular non-base layer with `nuh_layer_id` `nuhLayerId` and it is referred to by activation of a PPS RBSP (in which `pps_seq_parameter_set_id` is equal to the `sps_seq_parameter_set_id` value), or is referred to by an SEI NAL unit containing an active parameter sets SEI message (in which `active_seq_parameter_set_id[layer_sps_idx[LayerIdxInVps[nuhLayerId]]]` is equal to the `sps_seq_parameter_set_id` value), it is activated for the particular non-base layer. This SPS RBSP is called the active SPS RBSP for the particular non-base layer until it is deactivated by the activation of another SPS RBSP for the particular non-base layer. An SPS RBSP, with the particular value of `sps_seq_parameter_set_id`, shall be available to the decoding process prior to its activation, included in at least one access unit with `TemporalId` equal to 0 or provided through external means, and the SPS NAL unit containing the SPS RBSP shall have `nuh_layer_id` equal to 0, `nuhLayerId`, or `IdRefLayer[nuhLayerId][i]` with any value of `i` in the range of 0 to `NumRefLayers[nuhLayerId] - 1`, inclusive. An activated SPS RBSP for a particular layer shall remain active for the entire CLVS of that particular layer.

The contents of the `hrd_parameters()` syntax structure shall remain unchanged within a sequence of activated SPS RBSPs, in their activation order, from any activated SPS RBSP until the end of the bitstream or up to but excluding an SPS RBSP that is activated within the next access unit in which at least one of the following conditions is true:

- The access unit includes a picture for each `nuh_layer_id` value in `TargetDecLayerIdList` and each picture in the access unit is an IDR picture.
- The access unit includes an IRAP picture with `nuh_layer_id` equal to `SmallestLayerId` for which `NoClrasOutputFlag` is equal to 1.

Any SPS NAL unit with any `nuh_layer_id` value containing the value of `sps_seq_parameter_set_id` for the active SPS RBSP for a particular layer shall have the same content as that of the active SPS RBSP for the particular layer unless it follows the access unit `auA` containing the last coded picture for which the active SPS RBSP for the particular layer is required to be active for the particular layer and precedes the first NAL unit succeeding `auA` in decoding order that activates an SPS RBSP with the same value of `seq_parameter_set_id`.

NOTE 2 – All SPSs, regardless of their values of `nuh_layer_id`, share the same value space for `sps_seq_parameter_set_id`. In other words, an SPS with `nuh_layer_id` equal to `X` and `sps_seq_parameter_set_id` equal to `A` would update the previously received SPS with `nuh_layer_id` not equal to `X` and `sps_seq_parameter_set_id` equal to `A`.

When a VPS RBSP (with a particular value of `vps_video_parameter_set_id`) is not already active and it is referred to by activation of an SPS RBSP (in which `sps_video_parameter_set_id` is equal to the `vps_video_parameter_set_id` value), or is referred to by an SEI NAL unit containing an active parameter sets SEI message (in which `active_video_parameter_set_id` is equal to the `vps_video_parameter_set_id` value), it is activated. This VPS RBSP is called the active VPS RBSP until it is deactivated by the activation of another VPS RBSP. A VPS RBSP, with that particular value of `vps_video_parameter_set_id`, shall be available to the decoding process prior to its activation, included in at least one access unit with `TemporalId` equal to 0 or provided through external means, and the VPS NAL unit containing the VPS RBSP shall have `nuh_layer_id` equal to 0 or `SmallestLayerId`.

An activated VPS RBSP shall remain active until the end of the bitstream or until it is deactivated by another VPS RBSP in an access unit in which at least one of the following conditions is true:

- The access unit includes a picture for each `nuh_layer_id` value in `TargetDecLayerIdList` and each picture in the access unit is an IDR picture.
- The access unit includes an IRAP picture with `nuh_layer_id` equal to `SmallestLayerId` for which `NoClrasOutputFlag` is equal to 1.

For any VPS NAL unit within the CVS with any value of `nuh_layer_id` and the value of `vps_video_parameter_set_id` equal to that of the active VPS RBSP for a CVS, the VPS RBSP in the VPS NAL unit shall have the same content as that of the active VPS RBSP for the CVS.

All constraints that are expressed on the relationship between the values of the syntax elements and the values of variables derived from those syntax elements in VPSs, SPSs and PPSs and other syntax elements are expressions of constraints that apply only to the active VPS RBSP, the active SPS RBSP for any particular layer and the active PPS RBSP for any particular layer. If any VPS RBSP, SPS RBSP and PPS RBSP is present that is never activated in the bitstream, its syntax elements shall have values that would conform to the specified constraints if it was activated by reference in an otherwise conforming bitstream.

During operation of the decoding process for NAL units of a non-base layer, the values of parameters of the active VPS RBSP, the active SPS RBSP for the non-base layer and the active PPS RBSP for the non-base layer are considered in effect. For interpretation of SEI messages applicable to a coded picture of a non-base layer, the values of the active VPS RBSP, the active SPS RBSP for the non-base layer and the active PPS RBSP for the non-base layer for the operation of the decoding process for the VCL NAL units of the coded picture are considered in effect unless otherwise specified in the SEI message semantics.

F.7.4.2.4.3 Order of access units association to CVSs

A bitstream conforming to this Specification consists of one or more CVSs.

A CVS consists of one or more access units. The order of NAL units and coded pictures and their association to access units is described in clause F.7.4.2.4.4.

The first access unit of a CVS is an IRAP access unit with NoRaslOutputFlag equal to 1.

It is a requirement of bitstream conformance that, when present, the next access unit after an access unit that contains an end of sequence NAL unit with nuh_layer_id equal to SmallestLayerId or an end of bitstream NAL unit shall be an IRAP access unit.

F.7.4.2.4.4 Order of NAL units and coded pictures and association to access units

This clause specifies the order of NAL units and coded pictures and their association to access unit for CVSs that contain NAL units with nuh_layer_id greater than 0 that are decoded using the decoding processes specified in Annexes F, G and H.

An access unit consists of one or more coded pictures, each with a distinct value of nuh_layer_id, and zero or more non-VCL NAL units. The association of VCL NAL units to coded pictures is described in clause 7.4.2.4.5.

The first access unit in the bitstream starts with the first NAL unit of the bitstream.

A VCL NAL unit is the first VCL NAL unit of an access unit, when all of the following conditions are true:

- first_slice_segment_in_pic_flag is equal to 1.
- At least one of the following conditions is true:
 - The previous picture in decoding order belongs to a different picture order count (POC) resetting period than the picture containing the VCL NAL unit.
 - PicOrderCntVal derived for the VCL NAL unit differs from the PicOrderCntVal of the previous picture in decoding order.

NOTE 1 – For any two consecutive access units auA and auB that belong to the same POC resetting period, the PicOrderCntVal of pictures in auA cannot be the same as the PicOrderCntVal of pictures in auB.

NOTE 2 – Additionally, more conditions, e.g., the following conditions, could but does not need to be used:

- The nuh_layer_id value of the VCL NAL unit is equal to SmallestLayerId.
- vps_poc_lsb_aligned_flag is equal to 1 and the slice_pic_order_cnt_lsb value of the VCL NAL unit differs from the slice_pic_order_cnt_lsb value of the previous VCL NAL unit in decoding order.

The first of any of the following NAL units preceding the first VCL NAL unit firstVclNalUnitInAu and succeeding the last VCL NAL unit preceding firstVclNalUnitInAu, if any, specifies the start of a new access unit:

- Access unit delimiter NAL unit (when present).
- VPS NAL unit (when present)
- SPS NAL unit (when present)
- PPS NAL unit (when present)
- Prefix SEI NAL unit (when present)
- NAL units with nal_unit_type in the range of RSV_NVCL41..RSV_NVCL44 (when present)
- NAL units with nal_unit_type in the range of UNSPEC48..UNSPEC55 (when present)

When there is none of the above NAL units preceding firstVclNalUnitInAu and succeeding the last VCL NAL unit preceding firstVclNalUnitInAu, if any, firstVclNalUnitInAu starts a new access unit.

A coded picture with nuh_layer_id equal to nuhLayerIdA shall precede, in decoding order, all coded pictures with nuh_layer_id greater than nuhLayerIdA in the same access unit.

The order of the coded pictures and non-VCL NAL units within an access unit shall obey the following constraints:

- When an access unit delimiter NAL unit is present, it shall be the first NAL unit. There shall be at most one access unit delimiter NAL unit in any access unit.
- When any VPS NAL units, SPS NAL units, PPS NAL units, prefix SEI NAL units, NAL units with nal_unit_type in the range of RSV_NVCL41..RSV_NVCL44, or NAL units with nal_unit_type in the range of UNSPEC48..UNSPEC55 are present, they shall not follow the last VCL NAL unit of the access unit.

- NAL units having `nal_unit_type` equal to `FD_NUT` or `SUFFIX_SEI_NUT`, or in the range of `RSV_NVCL45..RSV_NVCL47` or `UNSPEC56..UNSPEC63` shall not precede the first VCL NAL unit of the access unit.
- When an end of sequence NAL unit with `nuh_layer_id` `nuhLayerId` is present, it shall be the last NAL unit with `nuh_layer_id` equal to `nuhLayerId` in the access unit other than an end of bitstream NAL unit (when present).
- When an end of bitstream NAL unit is present, it shall be the last NAL unit in the access unit.

F.7.4.2.4.5 Order of VCL NAL units and association to coded pictures

The specifications in clause 7.4.2.4.5 apply.

F.7.4.3 Raw byte sequence payloads, trailing bits and byte alignment semantics

F.7.4.3.1 Video parameter set RBSP semantics

The specifications in clause 7.4.3.1 apply with the replacement of references to Annex C with references to clause F.13, with the replacement of the semantics of the syntax elements `vps_extension_flag` and `vps_extension_data_flag` with that specified below and with the following additions:

Each output operation point is associated with an operation point, a list of `nuh_layer_id` values of the output layers, in increasing order of `nuh_layer_id` values, denoted as `OpLayerIdList`, and the `OpTid` of the associated operation point. The `OpLayerIdList` of the operation point associated with an output operation point is also referred to as the `OpLayerIdList` of the output operation point.

`vps_extension_flag` equal to 0 specifies that no `vps_extension()` syntax structure is present in the VPS RBSP syntax structure. `vps_extension_flag` equal to 1 specifies that the `vps_extension()` syntax structure is present in the VPS RBSP syntax structure. When `MaxLayersMinus1` is greater than 0, `vps_extension_flag` shall be equal to 1.

`vps_extension_alignment_bit_equal_to_one` shall be equal to 1.

`vps_extension2_flag` equal to 0 specifies that no `vps_extension_data_flag` syntax elements are present in the VPS RBSP syntax structure. `vps_extension2_flag` equal to 1 specifies that `vps_extension_data_flag` syntax elements are present in the VPS RBSP syntax structure. Decoders conforming to a profile specified in Annexes A, G or H shall ignore all data that follow the value 1 for `vps_extension2_flag` in a VPS RBSP.

`vps_extension_data_flag` may have any value. Its presence and value do not affect the decoding process for the profiles specified in Annexes A, G or H. Decoders conforming to a profile specified in Annexes A, G or H shall ignore all `vps_extension_data_flag` syntax elements.

F.7.4.3.1.1 Video parameter set extension semantics

`splitting_flag` equal to 1 indicates that the `dimension_id[i][j]` syntax elements are not present and that the binary representation of the `nuh_layer_id` value in the NAL unit header are split into `NumScalabilityTypes` segments with lengths, in bits, according to the values of `dimension_id_len_minus1[j]` and that the values of `dimension_id[LayerIdxInVps[nuh_layer_id]][j]` are inferred from the `NumScalabilityTypes` segments. `splitting_flag` equal to 0 indicates that the syntax elements `dimension_id[i][j]` are present.

NOTE 1 – When `splitting_flag` is equal to 1, scalability identifiers of the present scalability dimensions can be derived from the `nuh_layer_id` syntax element in the NAL unit header by a bit masked copy. The respective bit mask for the *i*-th present scalability dimension is defined by the value of the `dimension_id_len_minus1[i]` syntax element and `dimBitOffset[i]` as specified in the semantics of `dimension_id_len_minus1[j]`.

`scalability_mask_flag[i]` equal to 1 indicates that `dimension_id` syntax elements corresponding to the *i*-th scalability dimension in Table F.1 are present. `scalability_mask_flag[i]` equal to 0 indicates that `dimension_id` syntax elements corresponding to the *i*-th scalability dimension are not present.

Table F.1 – Mapping of ScalabilityId to scalability dimensions

Scalability mask index	Scalability dimension	ScalabilityId mapping
0	Texture or depth	DepthLayerFlag
1	Multiview	ViewOrderIdx
2	Spatial/quality scalability	DependencyId
3	Auxiliary	AuxId
4-15	Reserved	

dimension_id_len_minus1[j] plus 1 specifies the length, in bits, of the **dimension_id**[i][j] syntax element.

When **splitting_flag** is equal to 1, the following applies:

- The variable **dimBitOffset**[0] is set equal to 0 and for j in the range of 1 to **NumScalabilityTypes** – 1, inclusive, **dimBitOffset**[j] is derived as follows:

$$\text{dimBitOffset}[j] = \sum_{\text{dimIdx}=0}^{j-1} (\text{dimension_id_len_minus1}[\text{dimIdx}] + 1) \quad (\text{F-2})$$

- The value of **dimension_id_len_minus1**[**NumScalabilityTypes** – 1] is inferred to be equal to 5 – **dimBitOffset**[**NumScalabilityTypes** – 1].
- The value of **dimBitOffset**[**NumScalabilityTypes**] is set equal to 6.

It is a requirement of bitstream conformance that when **NumScalabilityTypes** is greater than 0, **dimBitOffset**[**NumScalabilityTypes** – 1] shall be less than 6.

vps_nuh_layer_id_present_flag equal to 1 specifies that **layer_id_in_nuh**[i] for i from 1 to **MaxLayersMinus1**, inclusive, are present. **vps_nuh_layer_id_present_flag** equal to 0 specifies that **layer_id_in_nuh**[i] for i from 1 to **MaxLayersMinus1**, inclusive, are not present.

layer_id_in_nuh[i] specifies the value of the **nuh_layer_id** syntax element in VCL NAL units of the i-th layer. When i is greater than 0, **layer_id_in_nuh**[i] shall be greater than **layer_id_in_nuh**[i – 1]. For any value of i in the range of 0 to **MaxLayersMinus1**, inclusive, when not present, the value of **layer_id_in_nuh**[i] is inferred to be equal to i.

For i from 0 to **MaxLayersMinus1**, inclusive, the variable **LayerIdxInVps**[**layer_id_in_nuh**[i]] is set equal to i.

dimension_id[i][j] specifies the identifier of the j-th present scalability dimension type of the i-th layer. The number of bits used for the representation of **dimension_id**[i][j] is **dimension_id_len_minus1**[j] + 1 bits.

Depending on **splitting_flag**, the following applies:

- If **splitting_flag** is equal to 1, for i from 0 to **MaxLayersMinus1**, inclusive, and j from 0 to **NumScalabilityTypes** – 1, inclusive, **dimension_id**[i][j] is inferred to be equal to ((**layer_id_in_nuh**[i] & ((1 << **dimBitOffset**[j + 1]) – 1)) >> **dimBitOffset**[j]).
- Otherwise (**splitting_flag** is equal to 0), for j from 0 to **NumScalabilityTypes** – 1, inclusive, **dimension_id**[0][j] is inferred to be equal to 0.

The variable **ScalabilityId**[i][**smIdx**] specifying the identifier of the **smIdx**-th scalability dimension type of the i-th layer, and the variables **DepthLayerFlag**[**lId**], **ViewOrderIdx**[**lId**], **DependencyId**[**lId**], and **AuxId**[**lId**] specifying the depth flag, the view order index, the spatial/quality scalability identifier and the auxiliary identifier, respectively, of the layer with **nuh_layer_id** equal to **lId** are derived as follows:

```

NumViews = 1
for( i = 0; i <= MaxLayersMinus1; i++ ) {
    lId = layer_id_in_nuh[ i ]
    for( smIdx = 0; j = 0; smIdx < 16; smIdx++ ) {
        if( scalability_mask_flag[ smIdx ] )
            ScalabilityId[ i ][ smIdx ] = dimension_id[ i ][ j++ ]
        else
            ScalabilityId[ i ][ smIdx ] = 0
    }
    DepthLayerFlag[ lId ] = ScalabilityId[ i ][ 0 ]
    ViewOrderIdx[ lId ] = ScalabilityId[ i ][ 1 ]
    DependencyId[ lId ] = ScalabilityId[ i ][ 2 ]
    (F-3)
    AuxId[ lId ] = ScalabilityId[ i ][ 3 ]
    if( i > 0 ) {
        newViewFlag = 1
        for( j = 0; j < i; j++ )
            if( ViewOrderIdx[ lId ] == ViewOrderIdx[ layer_id_in_nuh[ j ] ] )
                newViewFlag = 0
        NumViews += newViewFlag
    }
}

```

AuxId[lld] equal to 0 specifies the layer with nuh_layer_id equal to lld does not contain auxiliary pictures. AuxId[lld] greater than 0 specifies the type of auxiliary pictures in layer with nuh_layer_id equal to lld as specified in Table F.2.

Table F.2 – Mapping of AuxId to the type of auxiliary pictures

AuxId	Name of AuxId	Type of auxiliary pictures	SEI message describing interpretation of auxiliary pictures
1	AUX_ALPHA	Alpha plane	Alpha channel information
2	AUX_DEPTH	Depth picture	Depth representation information
3..127		Reserved	
128..159		Unspecified	
160..255		Reserved	

NOTE 2 – The interpretation of auxiliary pictures associated with AuxId in the range of 128 to 159, inclusive, is specified through means other than the AuxId value.

AuxId[lld] shall be in the range of 0 to 2, inclusive, or 128 to 159, inclusive, for bitstreams conforming to this version of this Specification. Although the value of AuxId[lld] shall be in the range of 0 to 2, inclusive, or 128 to 159, inclusive, in this version of this Specification, decoders shall allow values of AuxId[lld] in the range of 0 to 255, inclusive.

It is a requirement of bitstream conformance that when AuxId[lld] is equal to AUX_ALPHA or AUX_DEPTH, either of the following applies:

- chroma_format_idc is equal to 0 in the active SPS for the layer with nuh_layer_id equal to lld.
- The value of all decoded chroma samples is equal to 1 << (BitDepth_C – 1) in all pictures that have nuh_layer_id equal to lld and for which this VPS RBSP is the active VPS RBSP.

SEI messages may describe the interpretation of auxiliary pictures, including their possible association with one or more primary pictures.

NOTE 3 – Unless constrained by the semantics of the SEI messages specifying the interpretation of auxiliary pictures, it is allowed to have two layers with nuh_layer_id values layerIdA and layerIdB such that AuxId[layerIdA] is equal to AuxId[layerIdB], both being greater than 0 and to have all values of ScalabilityId[LayerIdxInVps[layerIdA]][i] equal to ScalabilityId[LayerIdxInVps[layerIdB]][i] for each value of i in the range of 0 to 15, inclusive. SEI messages specifying the interpretation of auxiliary pictures may specify that a picture with nuh_layer_id equal to layerIdA and a picture with nuh_layer_id equal to layerIdB in the same access unit may both be associated with the same primary picture.

view_id_len specifies the length, in bits, of the view_id_val[i] syntax element.

view_id_val[i] specifies the view identifier of the i-th view specified by the VPS. The length of the view_id_val[i] syntax element is view_id_len bits. When not present, the value of view_id_val[i] is inferred to be equal to 0.

For each layer with nuh_layer_id equal to nuhLayerId, the value ViewId[nuhLayerId] is set equal to view_id_val[ViewOrderIdx[nuhLayerId]].

direct_dependency_flag[i][j] equal to 0 specifies that the layer with index j is not a direct reference layer for the layer with index i. **direct_dependency_flag[i][j]** equal to 1 specifies that the layer with index j is a direct reference layer for the layer with index i. When **direct_dependency_flag[i][j]** is not present for i and j in the range of 0 to MaxLayersMinus1, it is inferred to be equal to 0.

The variable DependencyFlag[i][j] is derived as follows:

```

for( i = 0; i <= MaxLayersMinus1; i++ )
    for( j = 0; j <= MaxLayersMinus1; j++ ) {
        DependencyFlag[ i ][ j ] = direct_dependency_flag[ i ][ j ]
        for( k = 0; k < i; k++ )
            if( direct_dependency_flag[ i ][ k ] && DependencyFlag[ k ][ j ] )
                DependencyFlag[ i ][ j ] = 1
    }

```

(F-4)

The variables NumDirectRefLayers[iNuhLid], IdDirectRefLayer[iNuhLid][d], NumRefLayers[iNuhLid], IdRefLayer[iNuhLid][r], NumPredictedLayers[iNuhLid] and IdPredictedLayer[iNuhLid][p] are derived as follows:

```

for( i = 0; i <= MaxLayersMinus1; i++ ) {
    iNuhLid = layer_id_in_nuh[ i ]
    for( j = 0, d = 0, r = 0, p = 0; j <= MaxLayersMinus1; j++ ) {
        jNuhLid = layer_id_in_nuh[ j ]

```

```

        if( direct_dependency_flag[ i ][ j ] )
            IdDirectRefLayer[ iNuhLid ][ d++ ] = jNuhLid
        if( DependencyFlag[ i ][ j ] )
            IdRefLayer[ iNuhLid ][ r++ ] = jNuhLid
        if( DependencyFlag[ j ][ i ] )
            IdPredictedLayer[ iNuhLid ][ p++ ] = jNuhLid
    }
    NumDirectRefLayers[ iNuhLid ] = d
    NumRefLayers[ iNuhLid ] = r
    NumPredictedLayers[ iNuhLid ] = p
}

```

The variables NumIndependentLayers, NumLayersInTreePartition[i] and TreePartitionLayerIdList[i][j] for i in the range of 0 to NumIndependentLayers – 1, inclusive, and j in the range of 0 to NumLayersInTreePartition[i] – 1, inclusive, are derived as follows:

```

for( i = 0; i <= 63; i++ )
    layerIdInListFlag[ i ] = 0
for( i = 0, k = 0; i <= MaxLayersMinus1; i++ ) {
    iNuhLid = layer_id_in_nuh[ i ]
    if( NumDirectRefLayers[ iNuhLid ] == 0 ) {
        TreePartitionLayerIdList[ k ][ 0 ] = iNuhLid
        for( j = 0, h = 1; j < NumPredictedLayers[ iNuhLid ]; j++ ) {
            predLid = IdPredictedLayer[ iNuhLid ][ j ]
            if( !layerIdInListFlag[ predLid ] ) {
                TreePartitionLayerIdList[ k ][ h++ ] = predLid
                layerIdInListFlag[ predLid ] = 1
            }
        }
        NumLayersInTreePartition[ k++ ] = h
    }
}
NumIndependentLayers = k

```

It is a requirement of bitstream conformance that AuxId[IdDirectRefLayer[nuhLayerIdA][j]] for any values of nuhLayerIdA and j shall be equal to AuxId[nuhLayerIdA], when AuxId[nuhLayerIdA] is in the range of 0 to 2, inclusive.

NOTE 4 – In other words, no prediction takes place between layers with a different value of AuxId, when AuxId is in the range of 0 to 2, inclusive.

num_add_layer_sets specifies the number of additional layer sets. The value of num_add_layer_sets shall be in the range of 0 to 1 023, inclusive. When vps_base_layer_available_flag is equal to 0, the value of num_add_layer_sets shall be greater than 0. When not present, the value of num_add_layer_sets is inferred to be equal to 0.

The variable NumLayerSets is derived as follows:

$$\text{NumLayerSets} = \text{vps_num_layer_sets_minus1} + 1 + \text{num_add_layer_sets} \quad (\text{F-7})$$

When num_add_layer_sets is greater than 0, the variables FirstAddLayerSetIdx and LastAddLayerSetIdx are derived as follows:

$$\begin{aligned} \text{FirstAddLayerSetIdx} &= \text{vps_num_layer_sets_minus1} + 1 \\ \text{LastAddLayerSetIdx} &= \text{FirstAddLayerSetIdx} + \text{num_add_layer_sets} - 1 \end{aligned} \quad (\text{F-8})$$

highest_layer_idx_plus1[i][j] specifies the values of NumLayersInIdList[vps_num_layer_sets_minus1 + 1 + i] and LayerSetLayerIdList[vps_num_layer_sets_minus1 + 1 + i][layerNum] as follows:

```

layerNum = 0
lsIdx = vps_num_layer_sets_minus1 + 1 + i
for( treeIdx = 1; treeIdx < NumIndependentLayers; treeIdx++ )
    for( layerCnt = 0; layerCnt < highest_layer_idx_plus1[ i ][ treeIdx ]; layerCnt++ )
        LayerSetLayerIdList[ lsIdx ][ layerNum++ ] =
            TreePartitionLayerIdList[ treeIdx ][ layerCnt ]
    NumLayersInIdList[ lsIdx ] = layerNum

```

The value of `highest_layer_idx_plus1[i][j]` shall be in the range of 0 to `NumLayersInTreePartition[j]`, inclusive.

The length of the `highest_layer_idx_plus1[i][j]` syntax element is $\text{Ceil}(\log_2(\text{NumLayersInTreePartition}[j] + 1))$ bits.

It is a requirement of bitstream conformance that `NumLayersInIdList[vps_num_layer_sets_minus1 + 1 + i]` shall be greater than 0.

vps_sub_layers_max_minus1_present_flag equal to 1 specifies that the syntax elements `sub_layers_vps_max_minus1[i]` are present. **vps_sub_layers_max_minus1_present_flag** equal to 0 specifies that the syntax elements `sub_layers_vps_max_minus1[i]` are not present.

sub_layers_vps_max_minus1[i] plus 1 specifies, for each value of *i* in the range of (`vps_base_layer_internal_flag ? 0 : 1`) to `MaxLayersMinus1`, inclusive, the maximum number of temporal sub-layers that may be present in the CVS for the layer with `nuh_layer_id` `layerId` equal to `layer_id_in_nuh[i]`. When `vps_base_layer_internal_flag` is equal to 0, `sub_layers_vps_max_minus1[0]` constrains the access units for which a decoded picture with `nuh_layer_id` equal to 0 may be provided by external means as follows: a decoded picture with `nuh_layer_id` equal to 0 cannot be provided by external means for decoding of an access unit with `TemporalId` greater than `sub_layers_vps_max_minus1[0]`. The value of `sub_layers_vps_max_minus1[i]` shall be in the range of 0 to `vps_max_sub_layers_minus1`, inclusive. When not present, the value of `sub_layers_vps_max_minus1[i]` is inferred to be equal to `vps_max_sub_layers_minus1`.

The variable `MaxSubLayersInLayerSetMinus1[i]` is derived as follows:

```
for( i = 0; i < NumLayerSets; i++ ) {
    maxSMinus1 = 0
    for( k = 0; k < NumLayersInIdList[i]; k++ ) {
        lId = LayerSetLayerIdList[i][k]
        maxSMinus1 = Max( maxSMinus1,
            sub_layers_vps_max_minus1[LayerIdxInVps[lId]] )
    }
    MaxSubLayersInLayerSetMinus1[i] = maxSMinus1
}
```

(F-10)

max_tid_ref_present_flag equal to 1 specifies that the syntax element `max_tid_il_ref_pics_plus1[i][j]` is present. **max_tid_ref_present_flag** equal to 0 specifies that the syntax element `max_tid_il_ref_pics_plus1[i][j]` is not present.

max_tid_il_ref_pics_plus1[i][j] equal to 0 specifies that non-IRAP pictures with `nuh_layer_id` equal to `layer_id_in_nuh[i]` are not used as source pictures for inter-layer prediction for pictures with `nuh_layer_id` equal to `layer_id_in_nuh[j]`. **max_tid_il_ref_pics_plus1[i][j]** greater than 0 specifies that pictures with `nuh_layer_id` equal to `layer_id_in_nuh[i]` and `TemporalId` greater than `max_tid_il_ref_pics_plus1[i][j] - 1` are not used as source pictures for inter-layer prediction for pictures with `nuh_layer_id` equal to `layer_id_in_nuh[j]`. When not present, the value of `max_tid_il_ref_pics_plus1[i][j]` is inferred to be equal to 7.

default_ref_layers_active_flag equal to 1 specifies that for each picture referring to the VPS, the direct reference layer pictures that belong to all direct reference layers of the layer containing the picture and that may be used for inter-layer prediction as specified by the values of `sub_layers_vps_max_minus1[i]` and `max_tid_il_ref_pics_plus1[i][j]` are present in the same access unit as the picture and are included in the inter-layer reference picture set of the picture. **default_ref_layers_active_flag** equal to 0 specifies that the above restriction may or may not apply.

vps_num_profile_tier_level_minus1 plus 1 specifies the number of `profile_tier_level()` syntax structures in the VPS. The value of `vps_num_profile_tier_level_minus1` shall be in the range of 0 to 63, inclusive. When `vps_max_layers_minus1` is greater than 0, the value of `vps_num_profile_tier_level_minus1` shall be greater than or equal to 1.

vps_profile_present_flag[i] equal to 1 specifies that profile and tier information is present in the *i*-th `profile_tier_level()` syntax structure. **vps_profile_present_flag[i]** equal to 0 specifies that profile and tier information is not present in the *i*-th `profile_tier_level()` syntax structure and is inferred as specified in clause F.7.4.4.

num_add_olss specifies the number of OLSs in addition to the first `NumLayerSets` OLSs specified by the VPS. The value of `num_add_olss` shall be in the range of 0 to 1 023, inclusive. When not present, the value of `num_add_olss` is inferred to be equal to 0.

default_output_layer_idc specifies the derivation of the output layers for the OLSs with index in the range of 1 to `vps_num_layer_sets_minus1`, inclusive. **default_output_layer_idc** equal to 0 specifies that all layers in each of the OLSs with index in the range of 1 to `vps_num_layer_sets_minus1`, inclusive, are output layers of their respective OLSs. **default_output_layer_idc** equal to 1 specifies that only the layer with the highest value of `nuh_layer_id` such that `nuh_layer_id` equal to `nuhLayerIdA` in each of the OLSs with index in the range of 1 to `vps_num_layer_sets_minus1`, inclusive, is an output layer of its OLS. **default_output_layer_idc** equal to 2 specifies that the output layers for the OLSs with index in the range of 1 to `vps_num_layer_sets_minus1`, inclusive, are specified with the syntax elements

output_layer_flag[i][j]. The value of 3 for default_output_layer_idc is reserved for future use by ITU-T | ISO/IEC. Although the value of default_output_layer_idc is required to be less than 3 in this version of this Specification, decoders shall allow a value of default_output_layer_idc equal to 3 to appear in the syntax.

The variable defaultOutputLayerIdc is set equal to Min(default_output_layer_idc, 2).

layer_set_idx_for_ols_minus1[i] plus 1 specifies the index of the layer set for the i-th OLS. The value of layer_set_idx_for_ols_minus1[i] shall be in the range of 0 to NumLayerSets – 2, inclusive. The length of the layer_set_idx_for_ols_minus1[i] syntax element is Ceil(Log2(NumLayerSets – 1)) bits. When not present, the value of layer_set_idx_for_ols_minus1[i] is inferred to be equal to 0.

For i in the range of 0 to NumOutputLayerSets – 1, inclusive, the variable OlsIdxToLsIdx[i] is derived as specified in the following:

$$\text{OlsIdxToLsIdx}[i] = (i < \text{NumLayerSets}) ? i : (\text{layer_set_idx_for_ols_minus1}[i] + 1) \quad (\text{F-11})$$

output_layer_flag[i][j] equal to 1 specifies that the j-th layer in the i-th OLS is an output layer. output_layer_flag[i][j] equal to 0 specifies that the j-th layer in the i-th OLS is not an output layer.

The value of output_layer_flag[0][0] is inferred to be equal to 1.

When defaultOutputLayerIdc is equal to 0 or 1, for i in the range of 0 to vps_num_layer_sets_minus1, inclusive, and j in the range of 0 to NumLayersInIdList[OlsIdxToLsIdx[i]] – 1, inclusive, the variable OutputLayerFlag[i][j] is derived as follows:

- If defaultOutputLayerIdc is equal to 0 or LayerSetLayerIdList[OlsIdxToLsIdx[i]][j] is equal to nuhLayerIdA, with nuhLayerIdA being the highest value in LayerSetLayerIdList[OlsIdxToLsIdx[i]], OutputLayerFlag[i][j] is set equal to 1.
- Otherwise, OutputLayerFlag[i][j] is set equal to 0.

For i in the range of (defaultOutputLayerIdc == 2) ? 0 : (vps_num_layer_sets_minus1 + 1) to NumOutputLayerSets – 1, inclusive, and j in the range of 0 to NumLayersInIdList[OlsIdxToLsIdx[i]] – 1, inclusive, the variable OutputLayerFlag[i][j] is set equal to output_layer_flag[i][j].

The variable NumOutputLayersInOutputLayerSet[i] is derived as follows:

$$\begin{aligned} \text{NumOutputLayersInOutputLayerSet}[i] &= 0 \\ \text{for}(j = 0; j < \text{NumLayersInIdList}[\text{OlsIdxToLsIdx}[i]]; j++) \{ \\ \quad \text{NumOutputLayersInOutputLayerSet}[i] &+= \text{OutputLayerFlag}[i][j] \\ \quad \text{if}(\text{OutputLayerFlag}[i][j]) \\ \quad \quad \text{OlsHighestOutputLayerId}[i] &= \text{LayerSetLayerIdList}[\text{OlsIdxToLsIdx}[i]][j] \end{aligned} \quad (\text{F-12})$$

It is a requirement of bitstream conformance that NumOutputLayersInOutputLayerSet[i] shall be greater than 0 for i in the range of 0 to NumOutputLayerSets – 1, inclusive.

The variables NumNecessaryLayers[olsIdx] and NecessaryLayerFlag[olsIdx][lIdx] are derived as follows:

$$\begin{aligned} \text{for}(\text{olsIdx} = 0; \text{olsIdx} < \text{NumOutputLayerSets}; \text{olsIdx}++) \{ \\ \quad \text{lsIdx} &= \text{OlsIdxToLsIdx}[\text{olsIdx}] \\ \quad \text{for}(\text{lsLayerIdx} = 0; \text{lsLayerIdx} < \text{NumLayersInIdList}[\text{lsIdx}]; \text{lsLayerIdx}++) \\ \quad \quad \text{NecessaryLayerFlag}[\text{olsIdx}][\text{lsLayerIdx}] &= 0 \\ \quad \text{for}(\text{lsLayerIdx} = 0; \text{lsLayerIdx} < \text{NumLayersInIdList}[\text{lsIdx}]; \text{lsLayerIdx}++) \\ \quad \quad \text{if}(\text{OutputLayerFlag}[\text{olsIdx}][\text{lsLayerIdx}]) \{ \\ \quad \quad \quad \text{NecessaryLayerFlag}[\text{olsIdx}][\text{lsLayerIdx}] &= 1 \\ \quad \quad \quad \text{currLayerId} &= \text{LayerSetLayerIdList}[\text{lsIdx}][\text{lsLayerIdx}] \\ \quad \quad \quad \text{for}(\text{rLsLayerIdx} = 0; \text{rLsLayerIdx} < \text{lsLayerIdx}; \text{rLsLayerIdx}++) \{ \\ \quad \quad \quad \quad \text{refLayerId} &= \text{LayerSetLayerIdList}[\text{lsIdx}][\text{rLsLayerIdx}] \\ \\ \quad \quad \quad \text{if}(\text{DependencyFlag}[\text{LayerIdxInVps}[\text{currLayerId}]][\text{LayerIdxInVps}[\text{refLayerId}]]) \\ \quad \quad \quad \quad \text{NecessaryLayerFlag}[\text{olsIdx}][\text{rLsLayerIdx}] &= 1 \\ \quad \quad \quad \} \\ \quad \quad \} \\ \quad \text{NumNecessaryLayers}[\text{olsIdx}] &= 0 \\ \quad \text{for}(\text{lsLayerIdx} = 0; \text{lsLayerIdx} < \text{NumLayersInIdList}[\text{lsIdx}]; \text{lsLayerIdx}++) \\ \quad \quad \text{NumNecessaryLayers}[\text{olsIdx}] &+= \text{NecessaryLayerFlag}[\text{olsIdx}][\text{lsLayerIdx}] \\ \} \end{aligned} \quad (\text{F-13})$$

It is a requirement of bitstream conformance that for each layer index `layerIdx` in the range of (`vps_base_layer_internal_flag ? 0 : 1`) to `MaxLayersMinus1`, inclusive, there shall be at least one OLS with index `olsIdx` such that `NecessaryLayerFlag[olsIdx][lsLayerIdx]` is equal to 1 for the value of `lsLayerIdx` for which `LayerSetLayerIdList[OlsIdxToLsIdx[olsIdx]][lsLayerIdx]` is equal to `layer_id_in_nuh[layerIdx]`.

NOTE 5 – In other words, each layer has to be an output layer or a reference layer of an output layer in at least one OLS.

It is a requirement of bitstream conformance that when `num_add_layer_sets` is greater than 0 and `olsIdx` has any such value that `OlsIdxToLsIdx[olsIdx]` is in the range of `FirstAddLayerSetIdx` to `LastAddLayerSetIdx`, inclusive, and `NumNecessaryLayers[olsIdx]` is equal to 1, `NecessaryLayerFlag[olsIdx][0]` shall be equal to 1.

NOTE 6 – In other words, when an additional layer set has exactly one necessary layer, the necessary layer is required to be the layer with the smallest `nuh_layer_id` value within the additional layer set.

profile_tier_level_idx[i][j] specifies the index, into the list of `profile_tier_level()` syntax structures in the VPS, of the `profile_tier_level()` syntax structure that applies to the `j`-th layer of the `i`-th OLS as specified in clause F.7.4.4. The length of the `profile_tier_level_idx[i][j]` syntax element is `Ceil(Log2(vps_num_profile_tier_level_minus1 + 1))` bits.

When `NecessaryLayerFlag[i][j]` is equal to 1 and `vps_num_profile_tier_level_minus1` is equal to 0, the value of `profile_tier_level_idx[i][j]` is inferred to be equal to 0.

When `vps_base_layer_internal_flag` is equal to 1, the following applies:

- If `vps_max_layers_minus1` is greater than 0, the value of `profile_tier_level_idx[0][0]` is inferred to be equal to 1.
- Otherwise (`vps_max_layers_minus1` is equal to 0), the value of `profile_tier_level_idx[0][0]` is inferred to be equal to 0.

When present, the value of `profile_tier_level_idx[i][j]` shall be in the range of (`vps_base_layer_internal_flag ? 0 : 1`) to `vps_num_profile_tier_level_minus1`, inclusive.

alt_output_layer_flag[i] equal to 0 specifies that an alternative output layer is not used for any output layer in the `i`-th OLS. **alt_output_layer_flag[i]** equal to 1 specifies that an alternative output layer may be used for the output layer in the `i`-th OLS.

When not present, the value of `alt_output_layer_flag[i]` is inferred to be equal to 0.

NOTE 7 – When `alt_output_layer_flag[olsIdx]` is equal to 0, pictures that do not belong to the output layers of the OLS with index `olsIdx` are not output. When `alt_output_layer_flag[olsIdx]` is equal to 1 and a picture belonging to the output layer of the OLS with index `olsIdx` is not present in an access unit or has `PicOutputFlag` equal to 0, a picture with the highest `nuh_layer_id` among those pictures of the access unit for which `PicOutputFlag` is equal to 1 and having the `nuh_layer_id` value among the `nuh_layer_id` values of the reference layers of the output layer is output.

For each value of `olsIdx` in the range of 0 to `NumOutputLayerSets – 1`, inclusive, the following applies:

- When `alt_output_layer_flag[olsIdx]` is equal to 1, the value of `pic_output_flag` shall be the same in the slice headers of an access unit that have `nuh_layer_id` value equal to `OlsHighestOutputLayerId[olsIdx]` or equal to the `nuh_layer_id` value of any reference layer of the layer with `nuh_layer_id` equal to `OlsHighestOutputLayerId[olsIdx]`.
- The variable `olsBitstream` is derived as follows:
 - Let `lsIdx` be equal to `OlsIdxToLsIdx[olsIdx]`.
 - If `lsIdx` is less than or equal to `vps_num_layer_sets_minus1`, let `olsBitstream` be the output of the sub-bitstream extraction process specified in clause F.10.1 with the following inputs: the current bitstream, `tIdTarget` equal to 6 and `layerIdListTarget` equal to `LayerSetLayerIdList[lsIdx]`.
 - Otherwise, let `olsBitstream` be the output of the sub-bitstream extraction process specified in clause F.10.3 with the following inputs: the current bitstream, `tIdTarget` equal to 6 and `layerIdListTarget` equal to `LayerSetLayerIdList[lsIdx]`.
- Let `truncatedOlsBitstream` be `olsBitstream` or be formed from the `olsBitstream` by removing access units preceding, in decoding order, any access unit with an IRAP picture having `nuh_layer_id` equal to `SmallestLayerId`.
- It is a requirement of bitstream conformance that when `alt_output_layer_flag[olsIdx]` is equal to 1, a bitstream that is formed by removing, from the `truncatedOlsBitstream`, any coded picture that is not used as a reference for prediction for any other picture and is not the only coded picture of an access unit is a conforming bitstream.

NOTE 8 – When `alt_output_layer_flag[olsIdx]` is equal to 1, encoders are required to set the values of `max_vps_dec_pic_buffering_minus1[i][k][j]` such that these values suffice also when pictures of an alternative output layer are marked as "needed for output" in the HRD.

vps_num_rep_formats_minus1 plus 1 specifies the number of the following `rep_format()` syntax structures in the VPS. The value of `vps_num_rep_formats_minus1` shall be in the range of 0 to 255, inclusive.

rep_format_idx_present_flag equal to 1 specifies that the syntax elements `vps_rep_format_idx[i]` are present. `rep_format_idx_present_flag` equal to 0 specifies that the syntax elements `vps_rep_format_idx[i]` are not present. When not present, the value of `rep_format_idx_present_flag` is inferred to be equal to 0.

vps_rep_format_idx[i] specifies the index, into the list of `rep_format()` syntax structures in the VPS, of the `rep_format()` syntax structure that applies to the layer with `nuh_layer_id` equal to `layer_id_in_nuh[i]`. When not present, the value of `vps_rep_format_idx[i]` is inferred to be equal to $\text{Min}(i, \text{vps_num_rep_formats_minus1})$. The value of `vps_rep_format_idx[i]` shall be in the range of 0 to `vps_num_rep_formats_minus1`, inclusive. The number of bits used for the representation of `vps_rep_format_idx[i]` is $\text{Ceil}(\text{Log2}(\text{vps_num_rep_formats_minus1} + 1))$.

max_one_active_ref_layer_flag equal to 1 specifies that at most one picture is used for inter-layer prediction for each picture in the CVS. `max_one_active_ref_layer_flag` equal to 0 specifies that more than one picture may be used for inter-layer prediction for each picture in the CVS.

vps_poc_lsb_aligned_flag equal to 0 specifies that the value of `slice_pic_order_cnt_lsb` may or may not be the same in different pictures of an access unit. `vps_poc_lsb_aligned_flag` equal to 1 specifies that the value of `slice_pic_order_cnt_lsb` is the same in all pictures of an access unit. Additionally, the value of `vps_poc_lsb_aligned_flag` affects the decoding process for picture order count in clause F.8.3.1. When not present, the value of `vps_poc_lsb_aligned_flag` is inferred to be equal to 0.

poc_lsb_not_present_flag[i] equal to 1 specifies that the `slice_pic_order_cnt_lsb` syntax element is not present in the slice headers of IDR pictures with `nuh_layer_id` equal to `layer_id_in_nuh[i]` in the CVS. `poc_lsb_not_present_flag[i]` equal to 0 specifies that `slice_pic_order_cnt_lsb` syntax element may or may not be present in the slice headers of IDR pictures with `nuh_layer_id` equal to `layer_id_in_nuh[i]` in the CVS. When not present, the value of `poc_lsb_not_present_flag[i]` is inferred to be equal to 0.

direct_dep_type_len_minus2 plus 2 specifies the number of bits of the `direct_dependency_type[i][j]` and the `direct_dependency_all_layers_type` syntax elements. In bitstreams conforming to this version of this Specification the value of `direct_dep_type_len_minus2` shall be equal to 0 or 1. Although the value of `direct_dep_type_len_minus2` shall be equal to 0 or 1 in this version of this Specification, decoders shall allow other values of `direct_dep_type_len_minus2` in the range of 0 to 30, inclusive, to appear in the syntax.

direct_dependency_all_layers_flag equal to 1 specifies that the syntax element `direct_dependency_type[i][j]` is not present and inferred from `direct_dependency_all_layers_type`. `direct_dependency_all_layers_flag` equal to 0 indicates that the syntax element `direct_dependency_type[i][j]` is present.

direct_dependency_all_layers_type, when present, specifies the inferred value of `direct_dependency_type[i][j]` for all combinations of *i*-th and *j*-th layers. The length of the `direct_dependency_all_layers_type` syntax element is `direct_dep_type_len_minus2` + 2 bits. Although the value of `direct_dependency_all_layers_type` is required to be in the range of 0 to 6, inclusive, in this version of this Specification, decoders shall allow values of `direct_dependency_all_layers_type` in the range of 0 to $2^{32} - 2$, inclusive, to appear in the syntax.

direct_dependency_type[i][j] indicates the type of dependency between the layer with `nuh_layer_id` equal to `layer_id_in_nuh[i]` and the layer with `nuh_layer_id` equal to `layer_id_in_nuh[j]`. `direct_dependency_type[i][j]` equal to 0 specifies that the layer with `nuh_layer_id` equal to `layer_id_in_nuh[j]` may be used for inter-layer sample prediction but is not used for inter-layer motion prediction of the layer with `nuh_layer_id` equal to `layer_id_in_nuh[i]`. `direct_dependency_type[i][j]` equal to 1 specifies that the layer with `nuh_layer_id` equal to `layer_id_in_nuh[j]` may be used for inter-layer motion prediction but is not used for inter-layer sample prediction of the layer with `nuh_layer_id` equal to `layer_id_in_nuh[i]`. `direct_dependency_type[i][j]` equal to 2 specifies that the layer with `nuh_layer_id` equal to `layer_id_in_nuh[j]` may be used for both inter-layer motion prediction and inter-layer sample prediction of the layer with `nuh_layer_id` equal to `layer_id_in_nuh[i]`. The length of the `direct_dependency_type[i][j]` syntax element is `direct_dep_type_len_minus2` + 2 bits. Although the value of `direct_dependency_type[i][j]` shall be in the range of 0 to 2, inclusive, when the layer with `nuh_layer_id` equal to `layer_id_in_nuh[i]` conforms to a profile specified in Annexes A, G or H, and in the range of 0 to 6, inclusive, when the layer with `nuh_layer_id` equal to `layer_id_in_nuh[i]` conforms to a profile specified in Annex I, decoders shall allow values of `direct_dependency_type[i][j]` in the range of 0 to $2^{32} - 2$, inclusive, to appear in the syntax.

When `direct_dependency_all_layers_flag` is equal to 1, for any *i* in the range of $(1 - \text{vps_base_layer_internal_flag}) + 1$ to `MaxLayersMinus1`, inclusive, and any *j* in the range of $1 - \text{vps_base_layer_internal_flag}$ to *i* - 1, inclusive, when `direct_dependency_flag[i][j]` is equal to 1, the value of `direct_dependency_type[i][j]` is inferred to be equal to `direct_dependency_all_layers_type`.

When `vps_base_layer_internal_flag` is equal to 0, for any *i* in the range of 1 to `MaxLayersMinus1`, inclusive, when `direct_dependency_flag[i][0]` is equal to 1, the value of `direct_dependency_type[i][0]` is inferred to be equal to 0.

The variables `VpsInterLayerSamplePredictionEnabled[i][j]` and `VpsInterLayerMotionPredictionEnabled[i][j]` are derived as follows:

```

if( direct_dependency_flag[ i ][ j ] )
    VpsInterLayerSamplePredictionEnabled[ i ][ j ] = ( direct_dependency_type[ i ][ j ] + 1 ) & 0x1
else
    VpsInterLayerSamplePredictionEnabled[ i ][ j ] = 0
if( direct_dependency_flag[ i ][ j ] )
    VpsInterLayerMotionPredictionEnabled[ i ][ j ] = ( ( direct_dependency_type[ i ][ j ] + 1 ) & 0x2 ) ?
1 : 0
else
    VpsInterLayerMotionPredictionEnabled[ i ][ j ] = 0

```

(F-14)

vps_non_vui_extension_length specifies the length of the non-VUI VPS extension data following this syntax element and before `vps_vui_present_flag`, in bytes. The value of `vps_non_vui_extension_length` shall be in the range of 0 to 4096, inclusive.

vps_non_vui_extension_data_byte may have any value. Decoders shall ignore the value of `vps_non_vui_extension_data_byte`. Its value does not affect the decoding process specified in this version of this Specification.

vps_vui_present_flag equal to 1 specifies that the `vps_vui()` syntax structure is present in the VPS. `vps_vui_present_flag` equal to 0 specifies that the `vps_vui()` syntax structure is not present in the VPS.

vps_vui_alignment_bit_equal_to_one shall be equal to 1.

F.7.4.3.1.2 Representation format semantics

chroma_and_bit_depth_vps_present_flag equal to 1 specifies that the syntax elements `chroma_format_vps_idc`, `bit_depth_vps_luma_minus8` and `bit_depth_vps_chroma_minus8` are present and that the syntax element `separate_colour_plane_vps_flag` may be present in the `rep_format()` structure. `chroma_and_bit_depth_vps_present_flag` equal to 0 specifies that the syntax elements `chroma_format_vps_idc`, `separate_colour_plane_vps_flag`, `bit_depth_vps_luma_minus8` and `bit_depth_vps_chroma_minus8` are not present and are inferred from the previous `rep_format()` syntax structure in the VPS. The value of `chroma_and_bit_depth_vps_present_flag` of the first `rep_format()` syntax structure in the VPS shall be equal to 1.

pic_width_vps_in_luma_samples, **pic_height_vps_in_luma_samples**, **chroma_format_vps_idc**, **separate_colour_plane_vps_flag**, **bit_depth_vps_luma_minus8** and **bit_depth_vps_chroma_minus8** are used for inference of the values of the SPS syntax elements `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `chroma_format_idc`, `separate_colour_plane_flag`, `bit_depth_luma_minus8` and `bit_depth_chroma_minus8`, respectively, for each SPS that refers to the VPS. When not present in the *i*-th `rep_format()` syntax structure in the VPS, the value of each of these syntax elements is inferred to be equal to the value of the corresponding syntax element in the (*i* – 1)-th `rep_format()` syntax structure in the VPS. `pic_width_vps_in_luma_samples` shall not be equal to 0 and shall be an integer multiple of `MinCbSizeY`. `pic_height_vps_in_luma_samples` shall not be equal to 0 and shall be an integer multiple of `MinCbSizeY`. The value of `chroma_format_vps_idc` shall be in the range of 0 to 3, inclusive. `bit_depth_vps_luma_minus8` shall be in the range of 0 to 8, inclusive. `bit_depth_vps_chroma_minus8` shall be in the range of 0 to 8, inclusive.

conformance_window_vps_flag equal to 1 specifies that the syntax elements `conf_win_vps_left_offset`, `conf_win_vps_right_offset`, `conf_win_vps_top_offset` and `conf_win_vps_bottom_offset` follow next in the `rep_format()` structure. `conformance_window_vps_flag` equal to 0 specifies that the syntax elements `conf_win_vps_left_offset`, `conf_win_vps_right_offset`, `conf_win_vps_top_offset` and `conf_win_vps_bottom_offset` are not present.

conf_win_vps_left_offset, **conf_win_vps_right_offset**, **conf_win_vps_top_offset** and **conf_win_vps_bottom_offset** are used for inference of the values of the SPS syntax elements `conf_win_left_offset`, `conf_win_right_offset`, `conf_win_top_offset` and `conf_win_bottom_offset`, respectively, for each SPS that refers to the VPS. When not present, the values of `conf_win_vps_left_offset`, `conf_win_vps_right_offset`, `conf_win_vps_top_offset` and `conf_win_vps_bottom_offset` are inferred to be equal to 0.

The value of `SubWidthC * (conf_win_vps_left_offset + conf_win_vps_right_offset)` shall be less than `pic_width_vps_in_luma_samples` and the value of `SubHeightC * (conf_win_vps_top_offset + conf_win_vps_bottom_offset)` shall be less than `pic_height_vps_in_luma_samples`.

F.7.4.3.1.3 DPB size semantics

For the *l*Idx-th layer set, the number of sub-DPBs is `NumLayersInIdList[lIdx]` and for each layer with a particular value of `nuh_layer_id` in the layer set, the sub-DPB with index `layerIdx` is assigned, where `LayerSetLayerIdList[lIdx][layerIdx]` is equal to `nuh_layer_id`.

sub_layer_flag_info_present_flag[i][j] equal to 1 specifies that **sub_layer_dpb_info_present_flag**[i][j] is present for j in the range of 1 to **MaxSubLayersInLayerSetMinus1**[**OlsIdxToLsIdx**[i]], inclusive. **sub_layer_flag_info_present_flag**[i] equal to 0 specifies that, for each value of j greater than 0, **sub_layer_dpb_info_present_flag**[i][j] is not present.

sub_layer_dpb_info_present_flag[i][j] equal to 1 specifies that **max_vps_dec_pic_buffering_minus1**[i][k][j] may be present for k in the range of 0 to **NumLayersInIdList**[**OlsIdxToLsIdx**[i]] - 1, inclusive, for the j-th sub-layer of the i-th OLS, and **max_vps_num_reorder_pics**[i][j] and **max_vps_latency_increase_plus1**[i][j] are present for the j-th sub-layer of the i-th OLS. **sub_layer_dpb_info_present_flag**[i][j] equal to 0 specifies that **max_vps_dec_pic_buffering_minus1**[i][k][j] for k in the range of 0 to **NumLayersInIdList**[**OlsIdxToLsIdx**[i]] - 1, inclusive, **max_vps_num_reorder_pics**[i][j] and **max_vps_latency_increase_plus1**[i][j] are not present. The value of **sub_layer_dpb_info_present_flag**[i][0] for any possible value of i is inferred to be equal to 1. When not present, the value of **sub_layer_dpb_info_present_flag**[i][j] for j greater than 0 and any possible value of i, is inferred to be equal to 0.

max_vps_dec_pic_buffering_minus1[i][k][j] plus 1, when **NecessaryLayerFlag**[i][k] is equal to 1, specifies the maximum number of decoded pictures, of the k-th layer in the i-th OLS for the CVS, that need to be stored in the DPB when **HighestTid** is equal to j.

When **NecessaryLayerFlag**[i][k] is equal to 1, the following applies for i in the range of 1 to **NumOutputLayerSets** - 1, inclusive:

- When j is greater than 0, **max_vps_dec_pic_buffering_minus1**[i][k][j] shall be greater than or equal to **max_vps_dec_pic_buffering_minus1**[i][k][j - 1].
- When **max_vps_dec_pic_buffering_minus1**[i][0][0] is not present, it is inferred to be equal to 0.
- When **max_vps_dec_pic_buffering_minus1**[i][k][j] is not present for j in the range of 1 to **MaxSubLayersInLayerSetMinus1**[**OlsIdxToLsIdx**[i]], inclusive, it is inferred to be equal to **max_vps_dec_pic_buffering_minus1**[i][k][j - 1].

max_vps_num_reorder_pics[i][j] specifies, when **HighestTid** is equal to j, the maximum allowed number of access units containing a picture with **PicOutputFlag** equal to 1 that can precede any access unit auA that contains a picture with **PicOutputFlag** equal to 1 in the i-th OLS in the CVS in decoding order and follow the access unit auA that contains a picture with **PicOutputFlag** equal to 1 in output order. When **max_vps_num_reorder_pics**[i][j] is not present for j in the range of 1 to **MaxSubLayersInLayerSetMinus1**[**OlsIdxToLsIdx**[i]], inclusive, due to **sub_layer_dpb_info_present_flag**[i][j] being equal to 0, it is inferred to be equal to **max_vps_num_reorder_pics**[i][j - 1].

max_vps_latency_increase_plus1[i][j] not equal to 0 is used to compute the value of **MaxVpsLatencyPictures**[i][j], which, when **HighestTid** is equal to j, specifies the maximum number of access units containing a picture with **PicOutputFlag** equal to 1 in the i-th OLS that can precede any access unit auA that contains a picture with **PicOutputFlag** equal to 1 in the CVS in output order and follow the access unit auA that contains a picture with **PicOutputFlag** equal to 1 in decoding order. When **max_vps_latency_increase_plus1**[i][j] is not present for j in the range of 1 to **MaxSubLayersInLayerSetMinus1**[**OlsIdxToLsIdx**[i]], inclusive, due to **sub_layer_dpb_info_present_flag**[i][j] being equal to 0, it is inferred to be equal to **max_vps_latency_increase_plus1**[i][j - 1].

When **max_vps_latency_increase_plus1**[i][j] is not equal to 0, the value of **MaxVpsLatencyPictures**[i][j] is specified as follows:

$$\text{MaxVpsLatencyPictures}[i][j] = \text{max_vps_num_reorder_pics}[i][j] + \text{max_vps_latency_increase_plus1}[i][j] - 1$$

(F-15)

When **max_vps_latency_increase_plus1**[i][j] is equal to 0, no corresponding limit is expressed. The value of **max_vps_latency_increase_plus1**[i][j] shall be in the range of 0 to $2^{32} - 2$, inclusive.

F.7.4.3.1.4 VPS VUI semantics

NOTE 1 – When **vps_vui_present_flag** is equal to 0, some of the VPS VUI flags, such as **cross_layer_pic_type_aligned_flag**, **tiles_not_in_use_flag** and **wpp_not_in_use_flag**, are not present and no value is inferred for them. In this case, the semantics of these flags are unspecified and it should be interpreted as such that it is unknown whether the constraints associated with these flags being equal to 1 apply or not; in other words, in this case those constraints may or may not apply.

cross_layer_pic_type_aligned_flag equal to 1 specifies that within a CVS that refers to the VPS, all VCL NAL units that belong to an access unit have the same value of **nal_unit_type**. **cross_layer_pic_type_aligned_flag** equal to 0 specifies that within a CVS that refers to the VPS, all VCL NAL units in each access unit may or may not have the same value of **nal_unit_type**.

cross_layer_irap_aligned_flag equal to 1 specifies that IRAP pictures in the CVS are cross-layer aligned, i.e., when a picture pictureA of a layer layerA in an access unit is an IRAP picture, each picture pictureB in the same access unit that

belongs to a direct reference layer of layerA or that belongs to a layer for which layerA is a direct reference layer of that layer is an IRAP picture and the VCL NAL units of pictureB have the same value of nal_unit_type as that of pictureA. cross_layer_irap_aligned_flag equal to 0 specifies that the above restriction may or may not apply. When not present, the value of cross_layer_irap_aligned_flag is inferred to be equal to vps_vui_present_flag.

all_layers_idr_aligned_flag equal to 1 indicates that within each access unit for which the VCL NAL units refer to the VPS, when one picture is an IRAP picture, all the pictures in the same access unit are IDR pictures and have the same value of nal_unit_type. all_layers_idr_aligned_flag equal to 0 specifies that the above restriction may or may not apply. When not present, the value of all_layers_idr_aligned_flag is inferred to be equal to 0.

bit_rate_present_vps_flag equal to 1 specifies that the syntax element bit_rate_present_flag[i][j] is present. bit_rate_present_vps_flag equal to 0 specifies that the syntax element bit_rate_present_flag[i][j] is not present.

pic_rate_present_vps_flag equal to 1 specifies that the syntax element pic_rate_present_flag[i][j] is present. pic_rate_present_vps_flag equal to 0 specifies that the syntax element pic_rate_present_flag[i][j] is not present.

bit_rate_present_flag[i][j] equal to 1 specifies that the bit rate information for the j-th subset of the i-th layer set is present. bit_rate_present_flag[i] equal to 0 specifies that the bit rate information for the j-th subset of the i-th layer set is not present. The j-th subset of a layer set is derived as follows:

- If i is less than or equal to vps_num_layer_sets_minus1, the j-th subset of a layer set is the output of the sub-bitstream extraction process specified in clause F.10.1, when it is invoked with inBitstream equal to the layer set, tIdTarget equal to j and layerIdListTarget equal to the layer identifier list associated with the layer set as inputs.
- Otherwise (i is greater than vps_num_layer_sets_minus1), the j-th subset of a layer set is the output of the sub-bitstream extraction process specified in clause F.10.3, when it is invoked with inBitstream equal to the layer set, tIdTarget equal to j and layerIdListTarget equal to the layer identifier list associated with the layer set as inputs.

When not present, the value of bit_rate_present_flag[i][j] is inferred to be equal to 0.

pic_rate_present_flag[i][j] equal to 1 specifies that picture rate information for the j-th subset of the i-th layer set is present. pic_rate_present_flag[i][j] equal to 0 specifies that picture rate information for the j-th subset of the i-th layer set is not present. When not present, the value of pic_rate_present_flag[i][j] is inferred to be equal to 0.

avg_bit_rate[i][j] indicates the average bit rate of the j-th subset of the i-th layer set, in bits per second. The value is given by BitRateBPS(avg_bit_rate[i][j]) with the function BitRateBPS() being specified as follows:

$$\text{BitRateBPS}(x) = (x \& (2^{14} - 1)) * 10^{(2 + (x \gg 14))} \quad (\text{F-16})$$

The average bit rate is derived according to the access unit removal time specified in clause F.13. In the following, bTotal is the number of bits in all NAL units of the j-th subset of the i-th layer set, t₁ is the removal time (in seconds) of the first access unit to which the VPS applies and t₂ is the removal time (in seconds) of the last access unit (in decoding order) to which the VPS applies. With x specifying the value of avg_bit_rate[i][j], the following applies:

- If t₁ is not equal to t₂, the following condition shall be true:

$$(x \& (2^{14} - 1)) = \text{Round}(bTotal \div ((t_2 - t_1) * 10^{(2 + (x \gg 14))})) \quad (\text{F-17})$$

- Otherwise (t₁ is equal to t₂), the following condition shall be true:

$$(x \& (2^{14} - 1)) = 0 \quad (\text{F-18})$$

max_bit_rate_layer[i][j] indicates an upper bound for the bit rate of the j-th subset of the i-th layer set in any one-second time window of access unit removal time as specified in clause F.13. The upper bound for the bit rate in bits per second is given by BitRateBPS(max_bit_rate_layer[i][j]). The bit rate values are derived according to the access unit removal time specified in clause F.13. In the following, t₁ is any point in time (in seconds), t₂ is set equal to t₁ + 1 ÷ 100 and bTotal is the number of bits in all NAL units of access units with a removal time greater than or equal to t₁ and less than t₂. With x specifying the value of max_bit_rate_layer[i][j], the following condition shall be obeyed for all values of t₁:

$$(x \& (2^{14} - 1)) \geq bTotal \div ((t_2 - t_1) * 10^{(2 + (x \gg 14))}) \quad (\text{F-19})$$

constant_pic_rate_idc[i][j] indicates whether the picture rate of the j-th subset of the i-th layer set is constant. In the following, a temporal segment tSeg is any set of two or more consecutive access units, in decoding order, of the j-th subset of the i-th layer set, auTotal(tSeg) is the number of access units in the temporal segment tSeg, t₁(tSeg) is the removal time (in seconds) of the first access unit (in decoding order) of the temporal segment tSeg, t₂(tSeg) is the removal time (in seconds) of the last access unit (in decoding order) of the temporal segment tSeg, and avgPicRate(tSeg) is the average picture rate in the temporal segment tSeg, and is specified as follows:

$$\text{avgPicRate}(tSeg) = \text{Round}(auTotal(tSeg) * 256 \div (t_2(tSeg) - t_1(tSeg))) \quad (\text{F-20})$$

If the j -th subset of the i -th layer set only contains one or two access units or the value of $\text{avgPicRate}(t_{\text{Seg}})$ is constant over all the temporal segments, the picture rate is constant; otherwise, the picture rate is not constant.

$\text{constant_pic_rate_idc}[i][j]$ equal to 0 indicates that the picture rate of the j -th subset of the i -th layer set is not constant. $\text{constant_pic_rate_idc}[i][j]$ equal to 1 indicates that the picture rate of the j -th subset of the i -th layer set is constant. $\text{constant_pic_rate_idc}[i][j]$ equal to 2 indicates that the picture rate of the j -th subset of the i -th layer set may or may not be constant. The value of $\text{constant_pic_rate_idc}[i][j]$ shall be in the range of 0 to 2, inclusive.

$\text{avg_pic_rate}[i]$ indicates the average picture rate, in units of picture per 256 seconds, of the j -th subset of the layer set. With auTotal being the number of access units in the j -th subset of the i -th layer set, t_1 being the removal time (in seconds) of the first access unit to which the VPS applies, and t_2 being the removal time (in seconds) of the last access unit (in decoding order) to which the VPS applies, the following applies:

- If t_1 is not equal to t_2 , the following condition shall be true:

$$\text{avg_pic_rate}[i] == \text{Round}(\text{auTotal} * 256 \div (t_2 - t_1)) \quad (\text{F-21})$$

- Otherwise (t_1 is equal to t_2), the following condition shall be true:

$$\text{avg_pic_rate}[i] == 0 \quad (\text{F-22})$$

video_signal_info_idx_present_flag equal to 1 specifies that the syntax elements $\text{vps_num_video_signal_info_minus1}$ is present and the syntax element $\text{vps_video_signal_info_idx}[i]$ may be present. **video_signal_info_idx_present_flag** equal to 0 specifies that the syntax elements $\text{vps_num_video_signal_info_minus1}$ and $\text{vps_video_signal_info_idx}[i]$ are not present.

vps_num_video_signal_info_minus1 plus 1 specifies the number of the following $\text{video_signal_info}()$ syntax structures in the VPS. When not present, the value of $\text{vps_num_video_signal_info_minus1}$ is inferred to be equal to $\text{MaxLayersMinus1} - (\text{vps_base_layer_internal_flag} ? 0 : 1)$.

vps_video_signal_info_idx $[i]$ specifies the index, into the list of $\text{video_signal_info}()$ syntax structures in the VPS, of the $\text{video_signal_info}()$ syntax structure that applies to the layer with nuh_layer_id equal to $\text{layer_id_in_nuh}[i]$. If **video_signal_info_idx_present_flag** is equal to 0, the value of $\text{vps_video_signal_info_idx}[i]$ for each value of i in the range of $(\text{vps_base_layer_internal_flag} ? 0 : 1)$ to MaxLayersMinus1 , inclusive, is inferred to be equal to i . Otherwise, when $\text{vps_num_video_signal_info_minus1}$ is equal to 0, the value of $\text{vps_video_signal_info_idx}[i]$ for each value of i in the range of $\text{vps_base_layer_internal_flag}$ to MaxLayersMinus1 , inclusive, is inferred to be equal to 0. The value of $\text{vps_video_signal_info_idx}[i]$ for each value of i in the range of $(\text{vps_base_layer_internal_flag} ? 0 : 1)$ to MaxLayersMinus1 , inclusive, shall be in the range of 0 to $\text{vps_num_video_signal_info_minus1}$, inclusive.

tiles_not_in_use_flag equal to 1 indicates that the value of **tiles_enabled_flag** is equal to 0 for each PPS that is referred to by at least one picture referring to the VPS. **tiles_not_in_use_flag** equal to 0 indicates that such a restriction may or may not apply.

tiles_in_use_flag $[i]$ equal to 1 indicates that the value of **tiles_enabled_flag** is equal to 1 for each PPS that is referred to by at least one picture of the i -th layer specified by the VPS. **tiles_in_use_flag** $[i]$ equal to 0 indicates that such a restriction may or may not apply. When not present, the value of **tiles_in_use_flag** $[i]$ is inferred to be equal to 0.

loop_filter_not_across_tiles_flag $[i]$ equal to 1 indicates that the value of **loop_filter_across_tiles_enabled_flag** is equal to 0 for each PPS that is referred to by at least one picture of the i -th layer specified by the VPS. **loop_filter_not_across_tiles_flag** $[i]$ equal to 0 indicates that such a restriction may or may not apply. When not present, the value of **loop_filter_not_across_tiles_flag** $[i]$ is inferred to be equal to 0.

tile_boundaries_aligned_flag $[i][j]$ equal to 1 indicates that, when any two samples of one picture of the i -th layer specified by the VPS belong to one tile, the two collocated samples, when both present in the picture of the j -th direct reference layer of the i -th layer, belong to one tile, and when any two samples of one picture of the i -th layer belong to different tiles, the two collocated samples, when both present in the picture of the j -th direct reference layer of the i -th layer belong to different tiles. **tile_boundaries_aligned_flag** equal to 0 indicates that such a restriction may or may not apply. When not present, the value of **tile_boundaries_aligned_flag** $[i][j]$ is inferred to be equal to 0.

wpp_not_in_use_flag equal to 1 indicates that the value of **entropy_coding_sync_enabled_flag** is equal to 0 for each PPS that is referred to by at least one picture referring to the VPS. **wpp_not_in_use_flag** equal to 0 indicates that such a restriction may or may not apply.

wpp_in_use_flag $[i]$ equal to 1 indicates that the value of **entropy_coding_sync_enabled_flag** is equal to 1 for each PPS that is referred to by at least one picture of the i -th layer specified by the VPS. **wpp_in_use_flag** $[i]$ equal to 0 indicates that such a restriction may or may not apply. When not present, the value of **wpp_in_use_flag** $[i]$ is inferred to be equal to 0.

single_layer_for_non_irap_flag equal to 1 indicates the following:

- If `vps_base_layer_internal_flag` is equal to 1, `single_layer_for_non_irap_flag` equal to 1 indicates that either one of the following is true for each access unit for which this VPS is the active VPS:
 - All the VCL NAL units of an access unit have the same `nuh_layer_id` value.
 - Two `nuh_layer_id` values are used by the VCL NAL units of an access unit and the picture with the greater `nuh_layer_id` value is an IRAP picture.
- Otherwise (`vps_base_layer_internal_flag` is equal to 0), `single_layer_for_non_irap_flag` equal to 1 indicates that any one of the following is true for each access unit for which this VPS is the active VPS:
 - The decoded picture with `nuh_layer_id` equal to 0 is not provided for the access unit by external means and the access unit contains one coded picture.
 - The decoded picture with `nuh_layer_id` equal to 0 is not provided for the access unit by external means, the access unit contains two coded pictures and the picture with the greater `nuh_layer_id` value is an IRAP picture.
 - The decoded picture with `nuh_layer_id` equal to 0 is provided for an access unit by external means and the access unit contains one coded picture that is an IRAP picture.

`single_layer_for_non_irap_flag` equal to 0 indicates that the above constraints may or may not apply. When not present, the value of `single_layer_for_non_irap_flag` is inferred to be equal to 0.

higher_layer_irap_skip_flag equal to 1 indicates that each IRAP picture `currIrapPic` is constrained as specified below. `currIrapPic` is derived as follows for each access unit `currAu` for which this VPS is the active VPS:

- If `vps_base_layer_internal_flag` is equal to 1, `currAu` contains two coded pictures and the picture with the greater `nuh_layer_id` value is an IRAP picture, let `currIrapPic` be that IRAP picture.
- Otherwise, if `vps_base_layer_internal_flag` is equal to 0, a decoded picture with `nuh_layer_id` equal to 0 is not provided for `currAu` by external means, `currAu` contains two coded pictures and the picture with the greater `nuh_layer_id` value is an IRAP picture, let `currIrapPic` be that IRAP picture.
- Otherwise, if `vps_base_layer_internal_flag` is equal to 0, the decoded picture with `nuh_layer_id` equal to 0 is provided for `currAu` by external means and the access unit contains one coded picture that is an IRAP picture, let `currIrapPic` be that IRAP picture.
- Otherwise, `currIrapPic` is not derived for `currAu`.

The following constraints apply for each picture `currIrapPic`:

- For all slices of the IRAP picture:
 - `slice_type` shall be equal to P.
 - `slice_sao_luma_flag` and `slice_sao_chroma_flag` shall both be equal to 0.
 - `five_minus_max_num_merge_cand` shall be equal to 4.
 - `weighted_pred_flag` shall be equal to 0 in the PPS that is referred to by the slices.
- For all coding units of the IRAP picture:
 - `cu_skip_flag[i][j]` shall be equal to 1.

When `single_layer_for_non_irap_flag` is equal to 0, `higher_layer_irap_skip_flag` shall be equal to 0. When `higher_layer_irap_skip_flag` is not present it is inferred to be equal to 0.

NOTE 2 – When `vps_base_layer_internal_flag` is equal to 1, an encoder may set `single_layer_for_non_irap_flag` equal to 1 as an indication to a decoder that at most two pictures are present in any access unit and whenever there are two pictures in the same access unit, the one with the higher value of `nuh_layer_id` is an IRAP picture. The encoder may additionally set `higher_layer_irap_skip_flag` equal to 1 as an indication to a decoder that whenever there are two pictures in the same access unit, the one with the higher value of `nuh_layer_id` is an IRAP picture for which the decoded samples can be derived by applying the inter-layer reference picture derivation process specified in clause H.8.1.4 with the other picture with the lower value of `nuh_layer_id` as input.

ilp_restricted_ref_layers_flag equal to 1 indicates that additional restrictions on inter-layer prediction as specified below apply for each direct reference layer of each layer specified by the VPS. `ilp_restricted_ref_layers_flag` equal to 0 indicates that additional restrictions on inter-layer prediction may or may not apply. When not present, the value of `ilp_restricted_ref_layers_flag` is inferred to be equal to 0.

min_spatial_segment_offset_plus1[i][j] indicates the spatial region, in each picture of the j-th direct reference layer of the i-th layer, that is not used for inter-layer prediction for decoding of any picture of the i-th layer, by itself or together with `min_horizontal_ctu_offset_plus1[i][j]`, as specified below.

The variables `refLayerPicWidthInCtbsY[i][j]` and `refLayerPicHeightInCtbsY[i][j]` are set equal to `PicWidthInCtbsY` and `PicHeightInCtbsY`, respectively, of the j-th direct reference layer of the i-th layer.

The value of $\text{min_spatial_segment_offset_plus1}[i][j]$ shall be in the range of 0 to $\text{refLayerPicWidthInCtbsY}[i][j] * \text{refLayerPicHeightInCtbsY}[i][j]$, inclusive. When not present, the value of $\text{min_spatial_segment_offset_plus1}[i][j]$ is inferred to be equal to 0.

ctu_based_offset_enabled_flag $[i][j]$ equal to 1 specifies that the spatial region, in units of CTUs, in each picture of the j -th direct reference layer of the i -th layer, that is not used for inter-layer prediction for decoding of any picture of the i -th layer is indicated by $\text{min_spatial_segment_offset_plus1}[i][j]$ and $\text{min_horizontal_ctu_offset_plus1}[i][j]$ together. $\text{ctu_based_offset_enabled_flag}[i][j]$ equal to 0 specifies that the spatial region, in units of slice segments, tiles or CTU rows, in each picture of the j -th direct reference layer of the i -th layer, that is not used for inter-layer prediction for decoding of any picture of the i -th layer is indicated by $\text{min_spatial_segment_offset_plus1}[i]$ only. When not present, the value of $\text{ctu_based_offset_enabled_flag}[i]$ is inferred to be equal to 0.

min_horizontal_ctu_offset_plus1 $[i][j]$, when $\text{ctu_based_offset_enabled_flag}[i][j]$ is equal to 1, indicates the spatial region, in each picture of the j -th direct reference layer of the i -th layer, that is not used for inter-layer prediction for decoding of any picture of the i -th layer, together with $\text{min_spatial_segment_offset_plus1}[i][j]$, as specified below. The value of $\text{min_horizontal_ctu_offset_plus1}[i][j]$ shall be in the range of 0 to $\text{refLayerPicWidthInCtbsY}[i][j]$, inclusive.

When $\text{ctu_based_offset_enabled_flag}[i][j]$ is equal to 1, the variable $\text{minHorizontalCtbOffset}[i][j]$ is derived as follows:

$$\text{minHorizontalCtbOffset}[i][j] = (\text{min_horizontal_ctu_offset_plus1}[i][j] > 0) ? \quad (\text{F-23})$$

$$(\text{min_horizontal_ctu_offset_plus1}[i][j] - 1) : (\text{refLayerPicWidthInCtbsY}[i][j] - 1)$$

For any i in the range of 1 to MaxLayersMinus1 , inclusive, and any j in the range of 0 to $\text{NumDirectRefLayers}[\text{layer_id_in_nuh}[i]]$, inclusive, when $\text{min_spatial_segment_offset_plus1}[i][j]$ is greater than 0, it is a requirement of bitstream conformance that the following shall apply:

- Let picA be a picture in the i -th layer and let picB be the direct reference layer picture of picA with nuh_layer_id equal to $\text{IdDirectRefLayer}[\text{layer_id_in_nuh}[i]][j]$. The variable $\text{colCtbAddr}[i][j]$ that denotes the raster scan address of the collocated CTU, in the direct reference layer picture picB , of the CTU with raster scan address equal to $\text{ctbAddr}[i]$ in picA is derived as specified in the following:
 - The variables curPicWidthY , curPicHeightY , curCtbLog2SizeY and $\text{curPicWidthInCtbsY}$ are set equal to $\text{pic_width_in_luma_samples}$, $\text{pic_height_in_luma_samples}$, CtbLog2SizeY and PicWidthInCtbsY , respectively, of the i -th layer picture picA .
 - The variables refPicWidthY , refPicHeightY , refCtbLog2SizeY and $\text{refPicWidthInCtbsY}$ are set equal to $\text{pic_width_in_luma_samples}$, $\text{pic_height_in_luma_samples}$, CtbLog2SizeY and PicWidthInCtbsY , respectively, of the direct reference layer picture picB .
 - If $\text{scaled_ref_layer_offset_present_flag}[\text{IdDirectRefLayer}[\text{layer_id_in_nuh}[i]][j]]$ in the PPS referred to by the i -th layer picture picA is equal to 1, the variables scaledLeftOffset , scaledTopOffset , scaledRightOffset and $\text{scaledBottomOffset}$ are set equal to the left scaled reference layer offset $\text{ScaledRefLayerLeftOffset}$, the top scaled reference layer offset $\text{ScaledRefLayerTopOffset}$, the right scaled reference layer offset $\text{ScaledRefLayerRightOffset}$ and the bottom scaled reference layer offset $\text{ScaledRefLayerBottomOffset}$, respectively, for the direct reference layer picture picB of the i -th layer picture picA .
 - Otherwise ($\text{scaled_ref_layer_offset_present_flag}[\text{IdDirectRefLayer}[\text{layer_id_in_nuh}[i]][j]]$ is equal to 0), the variables scaledLeftOffset , scaledTopOffset , scaledRightOffset and $\text{scaledBottomOffset}$ are set equal to 0.
 - If $\text{ref_region_offset_present_flag}[\text{IdDirectRefLayer}[\text{layer_id_in_nuh}[i]][j]]$ in the PPS referred to by the i -th layer picture picA is equal to 1, the variables $\text{refRegionLeftOffset}$, $\text{refRegionTopOffset}$, $\text{refRegionRightOffset}$ and $\text{refRegionBottomOffset}$ are set equal to the left reference region offset $\text{RefLayerRegionLeftOffset}$, the top reference region offset $\text{RefLayerRegionTopOffset}$, the right reference region offset $\text{RefLayerRegionRightOffset}$ and the bottom reference region offset $\text{RefLayerRegionBottomOffset}$, respectively, for the direct reference layer picture picB of the i -th layer picture picA .
 - Otherwise ($\text{ref_region_offset_present_flag}[\text{IdDirectRefLayer}[\text{layer_id_in_nuh}[i]][j]]$ is equal to 0), the variables $\text{refRegionLeftOffset}$, $\text{refRegionTopOffset}$, $\text{refRegionRightOffset}$ and $\text{refRegionBottomOffset}$ are set equal to 0.
 - The variables (xP, yP) specifying the location of the top-left luma sample of the CTU with raster scan address equal to ctbAddr relative to top-left luma sample in picA are derived as follows:

$$xP = (\text{ctbAddr}[i] \% \text{curPicWidthInCtbsY}) \ll \text{curCtbLog2SizeY} \quad (\text{F-24})$$

$$yP = (\text{ctbAddr}[i] / \text{curPicWidthInCtbsY}) \ll \text{curCtbLog2SizeY} \quad (\text{F-25})$$

- The variables (xPCol, yPCol) specifying the collocated luma sample location in picB of the luma sample location (xP, yP) in picA are derived as follows:

$$\text{refRegionWidth} = \text{refPicWidthY} - \text{refRegionLeftOffset} - \text{refRegionRightOffset} \quad (\text{F-26})$$

$$\text{refRegionHeight} = \text{refPicHeightY} - \text{refRegionTopOffset} - \text{refRegionBottomOffset} \quad (\text{F-27})$$

$$\text{scaledRefRegionWidth} = \text{curPicHeightY} - \text{scaledLeftOffset} - \text{scaledRightOffset} \quad (\text{F-28})$$

$$\text{scaledRefRegionHeight} = \text{curPicHeightY} - \text{scaledTopOffset} - \text{scaledBottomOffset} \quad (\text{F-29})$$

$$\text{scaleX} = ((\text{refRegionWidth} \ll 16) + (\text{scaledRefRegionWidth} \gg 1)) / \text{scaledRefRegionWidth} \quad (\text{F-30})$$

$$\text{scaleY} = ((\text{refRegionHeight} \ll 16) + (\text{scaledRefRegionHeight} \gg 1)) / \text{scaledRefRegionHeight} \quad (\text{F-31})$$

$$\text{xPCol} = \text{Clip3}(0, (\text{refPicWidthY} - 1), \quad (\text{F-32})$$

$$((((\text{xP} - \text{scaledLeftOffset}) * \text{scaleX} + (1 \ll 15)) \gg 16) + \text{refRegionLeftOffset}))$$

$$\text{yPCol} = \text{Clip3}(0, (\text{refPicHeightY} - 1), \quad (\text{F-33})$$

$$((((\text{yP} - \text{scaledTopOffset}) * \text{scaleY} + (1 \ll 15)) \gg 16) + \text{refRegionTopOffset}))$$

- The variable colCtbAddr[i][j] is derived as follows:

$$\text{xColCtb}[i][j] = \text{xPCol} \gg \text{refCtbLog2SizeY} \quad (\text{F-34})$$

$$\text{yColCtb}[i][j] = \text{yPCol} \gg \text{refCtbLog2SizeY} \quad (\text{F-35})$$

$$\text{colCtbAddr}[i][j] = \text{xColCtb}[i][j] + (\text{yColCtb}[i][j] * \text{refPicWidthInCtbsY}) \quad (\text{F-36})$$

- If ctu_based_offset_enabled_flag[i][j] is equal to 0, exactly one of the following applies:
 - In each PPS referred to by a picture in the j-th direct reference layer of the i-th layer, tiles_enabled_flag is equal to 0 and entropy_coding_sync_enabled_flag is equal to 0 and the following applies:
 - Let slice segment A be any slice segment of a picture of the i-th layer and ctbAddr[i] be the raster scan address of the last CTU in slice segment A. Let slice segment B be the slice segment that belongs to the same access unit as slice segment A, belongs to the j-th direct reference layer of the i-th layer and contains the CTU with raster scan address colCtbAddr[i][j]. Let slice segment C be the slice segment that is in the same picture as slice segment B and follows slice segment B in decoding order, and between slice segment B and slice segment C there are min_spatial_segment_offset_plus1[i] – 1 slice segments in decoding order. When slice segment C is present, the syntax elements of slice segment A are constrained such that no sample or syntax elements values in slice segment C or any slice segment of the same picture following slice segment C in decoding order are used for inter-layer prediction in the decoding process of any samples within slice segment A.
 - In each PPS referred to by a picture in the j-th direct reference layer of the i-th layer, tiles_enabled_flag is equal to 1 and entropy_coding_sync_enabled_flag is equal to 0 and the following applies:
 - Let tile A be any tile in any picture picA of the i-th layer and ctbAddr[i] be the raster scan address of the last CTU in tile A. Let tile B be the tile that is in the picture picB belonging to the same access unit as picA and belonging to the j-th direct reference layer of the i-th layer and that contains the CTU with raster scan address colCtbAddr[i][j]. Let tile C be the tile that is also in picB and follows tile B in decoding order, and between tile B and tile C there are min_spatial_segment_offset_plus1[i] – 1 tiles in decoding order. When tile C is present, the syntax elements of tile A are constrained such that no sample or syntax elements values in tile C or any tile of the same picture following tile C in decoding order are used for inter-layer prediction in the decoding process of any samples within tile A.
 - In each PPS referred to by a picture in the j-th direct reference layer of the i-th layer, tiles_enabled_flag is equal to 0 and entropy_coding_sync_enabled_flag is equal to 1 and the following applies:
 - Let CTU row A be any CTU row in any picture picA of the i-th layer and ctbAddr[i] be the raster scan address of the last CTU in CTU row A. Let CTU row B be the CTU row that is in the picture picB belonging to the same access unit as picA and belonging to the j-th direct reference layer of the i-th layer and that contains the CTU with raster scan address colCtbAddr[i][j]. Let CTU row C be the CTU row that is also in picB and follows CTU row B in decoding order and between CTU row B and CTU row C there are

$\text{min_spatial_segment_offset_plus1}[i] - 1$ CTU rows in decoding order. When CTU row C is present, the syntax elements of CTU row A are constrained such that no sample or syntax elements values in CTU row C or row of the same picture following CTU row C are used for inter-layer prediction in the decoding process of any samples within CTU row A.

- Otherwise ($\text{ctu_based_offset_enabled_flag}[i][j]$ is equal to 1), the following applies:

- The variable $\text{refCtbAddr}[i][j]$ is derived as follows:

$$\begin{aligned} \text{xOffset}[i][j] = & \\ & ((\text{xColCtb}[i][j] + \text{minHorizontalCtbOffset}[i][j]) > (\text{refPicWidthInCtbsY}[i][j] - 1)) ? \\ & (\text{refPicWidthInCtbsY}[i][j] - 1 - \text{xColCtb}[i][j]) : \text{minHorizontalCtbOffset}[i][j] \quad (\text{F-37}) \end{aligned}$$

$$\text{yOffset}[i][j] = (\text{min_spatial_segment_offset_plus1}[i][j] - 1) * \text{refPicWidthInCtbsY}[i][j] \quad (\text{F-38})$$

$$\text{refCtbAddr}[i][j] = \text{colCtbAddr}[i][j] + \text{xOffset}[i][j] + \text{yOffset}[i][j] \quad (\text{F-39})$$

- Let CTU A be any CTU in any picture picA of the i -th layer, and $\text{ctbAddr}[i]$ be the raster scan address ctbAddr of CTU A. Let CTU B be a CTU that is in the picture belonging to the same access unit as picA and belonging to the j -th direct reference layer of the i -th layer and that has raster scan address greater than $\text{refCtbAddr}[i][j]$. When CTU B is present, the syntax elements of CTU A are constrained such that no sample or syntax elements values in CTU B are used for inter-layer prediction in the decoding process of any samples within CTU A.

vps_vui_bsp_hrd_present_flag equal to 0 specifies that no bitstream partition HRD parameters are present in the VPS VUI. **vps_vui_bsp_hrd_present_flag** equal to 1 specifies that bitstream partition HRD parameters are present in the VPS VUI. When **vps_timing_info_present_flag** is equal to 0, the value of **vps_vui_bsp_hrd_present_flag** shall be equal to 0.

base_layer_parameter_set_compatibility_flag $[i]$ equal to 1 specifies that the following constraints apply to the layer with nuh_layer_id equal to $\text{layer_id_in_nuh}[i]$. **base_layer_parameter_set_compatibility_flag** $[i]$ equal to 0 specifies that the following constraints may or may not apply to the layer with nuh_layer_id equal to $\text{layer_id_in_nuh}[i]$.

- Each coded slice segment NAL unit with nuh_layer_id value equal to $\text{layer_id_in_nuh}[i]$ referring to the VPS shall refer to a PPS with nuh_layer_id value equal to 0.
- Each coded slice segment NAL unit with nuh_layer_id value equal to $\text{layer_id_in_nuh}[i]$ referring to the VPS shall refer to a SPS with nuh_layer_id value equal to 0.
- The values of **chroma_format_idc**, **separate_colour_plane_flag**, **pic_width_in_luma_samples**, **pic_height_in_luma_samples**, **bit_depth_luma_minus8**, **bit_depth_chroma_minus8**, **conf_win_left_offset**, **conf_win_right_offset**, **conf_win_top_offset** and **conf_win_bottom_offset**, respectively, of the active SPS for the layer with nuh_layer_id equal to $\text{layer_id_in_nuh}[i]$ shall be the same as the values of **chroma_format_vps_idc**, **separate_colour_plane_vps_flag**, **pic_width_vps_in_luma_samples**, **pic_height_vps_in_luma_samples**, **bit_depth_vps_luma_minus8**, **bit_depth_vps_chroma_minus8**, **conf_win_vps_left_offset**, **conf_win_vps_right_offset**, **conf_win_vps_top_offset** and **conf_win_vps_bottom_offset**, respectively, of the $\text{vps_rep_format_idx}[i]$ -th **rep_format()** syntax structure in the active VPS.

F.7.4.3.1.5 Video signal info semantics

video_vps_format, **video_full_range_vps_flag**, **colour_primaries_vps**, **transfer_characteristics_vps** and **matrix_coeffs_vps** are used for inference of the values of the SPS VUI syntax elements **video_format**, **video_full_range_flag**, **colour_primaries**, **transfer_characteristics**, and **matrix_coeffs**, respectively, for each SPS that refers to the VPS.

For each of these syntax elements, all constraints, if any, that apply to the value of the corresponding SPS VUI syntax element also apply.

F.7.4.3.1.6 VPS VUI bitstream partition HRD parameters semantics

vps_num_add_hrd_params specifies the number of additional **hrd_parameters()** syntax structures present in the VPS. The value of **vps_num_add_hrd_params** shall be in the range of 0 to 1 024 – **vps_num_hrd_parameters**, inclusive.

cprms_add_present_flag $[i]$ equal to 1 specifies that the HRD parameters that are common for all sub-layers are present in the i -th **hrd_parameters()** syntax structure. **cprms_add_present_flag** $[i]$ equal to 0 specifies that the HRD parameters that are common for all sub-layers are not present in the i -th **hrd_parameters()** syntax structure and are derived to be the same as the $(i - 1)$ -th **hrd_parameters()** syntax structure. When **vps_num_hrd_parameters** is equal to 0, the value of **cprms_add_present_flag** $[0]$ is inferred to be equal to 1.

num_sub_layer_hrd_minus1 $[i]$ plus 1 specifies the number of sub-layers for which HRD parameters are signalled in

the `i`-th `hrd_parameters()` syntax structure. The value of `num_sub_layer_hrd_minus1[i]` shall be in the range of 0 to `vps_max_sub_layers_minus1`, inclusive.

num_signalled_partitioning_schemes[h] specifies the number of signalled partitioning schemes for the `h`-th output layer set (OLS). The value of `num_signalled_partitioning_schemes[h]` shall be in the range of 0 to 16, inclusive. When `vps_base_layer_internal_flag` is equal to 1, the value of `num_signalled_partitioning_schemes[0]` is inferred to be equal to 0.

num_partitions_in_scheme_minus1[h][j] plus 1 specifies the number of bitstream partitions for the `j`-th partitioning scheme of the `h`-th OLS. The value of `num_partitions_in_scheme_minus1[h][j]` shall be in the range of 0 to `NumLayersInIdList[OlsIdxToLsIdx[h]] - 1`, inclusive. When `vps_base_layer_internal_flag` is equal to 1, the value of `num_partitions_in_scheme_minus1[0][0]` is inferred to be equal to 0. The value of `num_partitions_in_scheme_minus1[h][0]` is inferred to be equal to `NumLayersInIdList[h] - 1`.

NOTE – The 0-th partitioning scheme for each OLS is inferred to contain the number of bitstream partitions to be equal to the number of layers in the OLS and each bitstream partition contains one layer of the OLS.

layer_included_in_partition_flag[h][j][k][r] equal to 1 specifies that the `r`-th layer in the `h`-th OLS is included in the `k`-th bitstream partition of the `j`-th partitioning scheme of the `h`-th OLS. **layer_included_in_partition_flag[h][j][k][r]** equal to 0 specifies that the `r`-th layer in the `h`-th OLS is not included in the `k`-th bitstream partition of the `j`-th partitioning scheme of the `h`-th OLS. When `vps_base_layer_internal_flag` is equal to 1, the value of **layer_included_in_partition_flag[0][0][0][0]** is inferred to be equal to 1. The value of **layer_included_in_partition_flag[h][0][k][r]** for any value of `h` in the range of 1 to `NumOutputLayerSets - 1`, inclusive, is inferred to be equal to (`k == r`).

It is a requirement of bitstream conformance that the following constraints apply:

- For the `j`-th partitioning scheme of the `h`-th OLS, the bitstream partition with index `k1` shall not include reference layers of any layers in the bitstream partition with index `k2` for any values of `k1` and `k2` in the range of 0 to `num_partitions_in_scheme_minus1[h][j]`, inclusive, such that `k2` is less than `k1`.
- When `vps_base_layer_internal_flag` is equal to 0 and **layer_included_in_partition_flag[h][j][k][0]** is equal to 1 for any value of `h` in the range of 1 to `NumOutputLayerSets - 1`, inclusive, any value of `j` in the range of 0 to `num_signalled_partitioning_schemes[h]`, inclusive, and any value of `k` in the range of 0 to `num_partitions_in_scheme_minus1[h][j]`, inclusive, the value of **layer_included_in_partition_flag[h][j][k][r]** for at least one value of `r` in the range of 1 to `NumLayersInIdList[OlsIdxToLsIdx[h]] - 1`, inclusive, shall be equal to 1.
- For each partitioning scheme with index `j` of the `h`-th OLS and for each layer with layer index `r` among the layers in the `h`-th OLS, there exists one and only one value of `k` in the range of 0 to `num_partitions_in_scheme_minus1[h][j]`, inclusive, such that **layer_included_in_partition_flag[h][j][k][r]** is equal to 1.

num_bsp_schedules_minus1[h][i][t] plus 1 specifies the number of delivery schedules specified for bitstream partitions of the `i`-th partitioning scheme of the `h`-th OLS when `HighestTid` is equal to `t`. The value of `num_bsp_schedules_minus1[h][i][t]` shall be in the range of 0 to 31, inclusive.

The variable `BspSchedCnt[h][i][t]` is set equal to `num_bsp_schedules_minus1[h][i][t] + 1`.

bsp_hrd_idx[h][i][t][j][k] specifies the index of the `hrd_parameters()` syntax structure in the VPS for the `j`-th delivery schedule specified for the `k`-th bitstream partition of the `i`-th partitioning scheme for the `h`-th OLS when `HighestTid` is equal to `t`. The length of the `bsp_hrd_idx[h][i][t][j][k]` syntax element is `Ceil(Log2(vps_num_hrd_parameters + vps_num_add_hrd_params))` bits. The value of `bsp_hrd_idx[h][i][t][j][k]` shall be in the range of 0 to `vps_num_hrd_parameters + vps_num_add_hrd_params - 1`, inclusive. When `vps_num_hrd_parameters + vps_num_add_hrd_params` is equal to 1, the value of `bsp_hrd_idx[h][i][t][j][k]` is inferred to be equal to 0.

bsp_sched_idx[h][i][t][j][k] specifies the index of the delivery schedule within the `sub_layer_hrd_parameters(t)` syntax structure of the `hrd_parameters()` syntax structure with the index `bsp_hrd_idx[h][i][t][j][k]`, that is used as the `j`-th delivery schedule specified for the `k`-th bitstream partition of the `i`-th partitioning scheme for the `h`-th OLS when `HighestTid` is equal to `t`. The value of `bsp_sched_idx[h][i][t][j][k]` shall be in the range of 0 to `cpb_cnt_minus1[t]`, inclusive, where `cpb_cnt_minus1[t]` is found in the `hrd_parameters()` syntax structure corresponding to the index `bsp_hrd_idx[h][i][t][j][k]`.

The following applies for any `j` greater than 0, any `h` in the range of 1 to `NumOutputLayerSets - 1`, inclusive, any `i` in the range 0 to `num_signalled_partitioning_schemes[h]`, inclusive, any `t` in the range of 0 to `MaxSubLayersInLayerSetMinus1[OlsIdxToLsIdx[h]]`, inclusive, and any `k` in the range of 0 to `num_partitions_in_scheme_minus1[h][i]`, inclusive:

- For `x` in the range of 0 to 1, inclusive, the following applies:
 - The variable `bsIdx` is set equal to `bsp_sched_idx[h][i][t][j - x][k]`.

- The variables `bitRateValueMinus1[x]`, `bitRateDuValueMinus1[x]`, `cpbSizeValueMinus1[x]` and `cpbSizeDuValueMinus1[x]` are set equal to the values of the syntax elements `bit_rate_value_minus1[bsIdx]`, `bit_rate_du_value_minus1[bsIdx]`, `cpb_size_value_minus1[bsIdx]` and `cpb_size_du_value_minus1[bsIdx]`, respectively, found in the `sub_layer_hrd_parameters(t)` syntax structure within the `hrd_parameters()` structure with index `bsp_hrd_idx[h][i][t][j - x][k]`.
- It is a requirement of bitstream conformance that all of the following conditions shall be true:
 - `bitRateValueMinus1[0]` is greater than `bitRateValueMinus1[1]`.
 - `bitRateDuValueMinus1[0]` is greater than `bitRateDuValueMinus1[1]`.
 - `cpbSizeValueMinus1[0]` is less than or equal to `cpbSizeValueMinus1[1]`.
 - `cpbSizeDuValueMinus1[0]` is less than or equal to `cpbSizeDuValueMinus1[1]`.

The arrays `BpBitRate` and `BpbSize` for bitstream partition buffer (BPB) are derived as follows:

```

for( h = 1; h < NumOutputLayerSets; h++ )
  for( i = 0; i <= num_signalled_partitioning_schemes[ h ]; i++ )
    for( t = 0; t <= MaxSubLayersInLayerSetMinus1[ OlsIdxToLsIdx[ h ] ]; t++ )
      for( j = 0; j <= num_bsp_schedules_minus1[ h ][ i ][ t ]; j++ )
        for( k = 0; k <= num_partitions_in_scheme_minus1[ h ][ i ][ t ][ j ]; k++ ) {
          bsIdx = bsp_sched_idx[ h ][ i ][ t ][ j ][ k ]
          brDu = ( bit_rate_du_value_minus1[ bsIdx ] + 1 ) * 2(6 + bit_rate_scale)
          brPu = ( bit_rate_value_minus1[ bsIdx ] + 1 ) * 2(6 + bit_rate_scale)
          cpbSizeDu = ( cpb_size_du_value_minus1[ bsIdx ] + 1 ) * 2(4 + cpb_size_du_scale)
          cpbSizePu = ( cpb_size_value_minus1[ bsIdx ] + 1 ) * 2(4 + cpb_size_scale)
          BpBitRate[ h ][ i ][ t ][ j ][ k ] = SubPicHrdFlag ? brDu : brPu
          BpbSize[ h ][ i ][ t ][ j ][ k ] = SubPicHrdFlag ? cpbSizeDu : cpbSizePu
        }

```

(F-40)

where the syntax elements `bit_rate_scale`, `cpb_size_du_scale` and `cpb_size_scale` values are found in the `hrd_parameters()` syntax structure corresponding to the index `bsp_hrd_idx[h][i][t][j][k]`, and the syntax elements `bit_rate_du_value_minus1[bsIdx]`, `bit_rate_value_minus1[bsIdx]`, `cpb_size_du_value_minus1[bsIdx]` and `cpb_size_value_minus1[bsIdx]` are found in the `sub_layer_hrd_parameters(t)` syntax structure within that `hrd_parameters()` syntax structure.

F.7.4.3.2 Sequence parameter set RBSP semantics

F.7.4.3.2.1 General sequence parameter set RBSP semantics

The specifications in clause 7.4.3.2.1 apply with the following additions and modifications:

sps_max_sub_layers_minus1 plus 1 specifies the maximum number of temporal sub-layers that may be present in each CVS referring to the SPS. The value of `sps_max_sub_layers_minus1` shall be in the range of 0 to 6, inclusive. The value of `sps_max_sub_layers_minus1` shall be less than or equal to `vps_max_sub_layers_minus1`. When not present, the value of `sps_max_sub_layers_minus1` is inferred to be equal to $(\text{sps_ext_or_max_sub_layers_minus1} == 7) ? \text{vps_max_sub_layers_minus1} : \text{sps_ext_or_max_sub_layers_minus1}$.

sps_ext_or_max_sub_layers_minus1 is used to infer the value of `sps_max_sub_layers_minus1` and to derive the value of `MultiLayerExtSpsFlag`.

It is a requirement of bitstream conformance that the following applies:

- If the SPS is referred to by any current picture that belongs to an independent non-base layer, the value of `MultiLayerExtSpsFlag` derived from the SPS shall be equal to 0.
- Otherwise, the value of `MultiLayerExtSpsFlag` derived from the SPS shall be equal to 1.

sps_temporal_id_nesting_flag, when `sps_max_sub_layers_minus1` is greater than 0, specifies whether inter prediction is additionally restricted for CVSs referring to the SPS. When `vps_temporal_id_nesting_flag` is equal to 1, `sps_temporal_id_nesting_flag` shall be equal to 1. When `sps_max_sub_layers_minus1` is equal to 0, `sps_temporal_id_nesting_flag` shall be equal to 1. When not present, the value of `sps_temporal_id_nesting_flag` is inferred as follows:

- If `sps_max_sub_layers_minus1` is greater than 0, the value of `sps_temporal_id_nesting_flag` is inferred to be equal to `vps_temporal_id_nesting_flag`.

- Otherwise, the value of `sps_temporal_id_nesting_flag` is inferred to be equal to 1.

NOTE 1 – The syntax element `sps_temporal_id_nesting_flag` is used to indicate that temporal up-switching, i.e., switching from decoding up to any TemporalId tIdN to decoding up to any TemporalId tIdM that is greater than tIdN, is always possible in the CVS.

update_rep_format_flag equal to 1 specifies that `sps_rep_format_idx` is present and that the `sps_rep_format_idx`-th `rep_format()` syntax structures in the active VPS applies to the layers that refer to this SPS. `update_rep_format_flag` equal to 0 specifies that `sps_rep_format_idx` is not present. When the value of `vps_num_rep_formats_minus1` in the active VPS is equal to 0, it is a requirement of bitstream conformance that the value of `update_rep_format_flag` shall be equal to 0. When not present, the value of `update_rep_format_flag` is inferred to be equal to 0.

sps_rep_format_idx specifies the index, into the list of `rep_format()` syntax structures in the VPS, of the `rep_format()` syntax structure that applies to the layers that refer to this SPS. The value of `sps_rep_format_idx` shall be in the range of 0 to `vps_num_rep_formats_minus1`, inclusive.

When a current picture with `nuh_layer_id` `layerIdCurr` greater than 0 refers to an SPS and the layer with `nuh_layer_id` equal to `layerIdCurr` is not an independent non-base layer, the values of `chroma_format_idc`, `separate_colour_plane_flag`, `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `conf_win_left_offset`, `conf_win_right_offset`, `conf_win_top_offset` and `conf_win_bottom_offset` are inferred or constrained as follows:

- The variable `repFormatIdx` is derived as follows:
 - If `update_rep_format_flag` is equal to 0, the variable `repFormatIdx` is set equal to `vps_rep_format_idx[LayerIdxInVps[layerIdCurr]]`.
 - Otherwise (`update_rep_format_flag` is equal to 1), `repFormatIdx` is set equal to `sps_rep_format_idx`.
- If `MultiLayerExtSpsFlag` derived from the active SPS for the layer with `nuh_layer_id` equal to `layerIdCurr` is equal to 0, the values of `chroma_format_idc`, `separate_colour_plane_flag`, `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `conf_win_left_offset`, `conf_win_right_offset`, `conf_win_top_offset` and `conf_win_bottom_offset`, are inferred to be equal to `chroma_format_vps_idc`, `separate_colour_plane_vps_flag`, `pic_width_vps_in_luma_samples`, `pic_height_vps_in_luma_samples`, `bit_depth_vps_luma_minus8`, `bit_depth_vps_chroma_minus8`, `conf_win_vps_left_offset`, `conf_win_vps_right_offset`, `conf_win_vps_top_offset` and `conf_win_vps_bottom_offset`, respectively, of the `repFormatIdx`-th `rep_format()` syntax structure in the active VPS and the values of `chroma_format_idc`, `separate_colour_plane_flag`, `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `conf_win_left_offset`, `conf_win_right_offset`, `conf_win_top_offset` and `conf_win_bottom_offset` signalled in the active SPS for the layer with `nuh_layer_id` equal to `layerIdCurr` are ignored.

NOTE 2 – The values are inferred from the VPS when a layer that is not an independent layer refers to an SPS that is also referred to by the base layer, in which case the SPS has `nuh_layer_id` equal to 0. For independent layers, the values of these parameters in the active SPS for the base layer apply.

- Otherwise, the values of `chroma_format_idc`, `separate_colour_plane_flag`, `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `conf_win_left_offset`, `conf_win_right_offset`, `conf_win_top_offset` and `conf_win_bottom_offset` are inferred to be equal to `chroma_format_vps_idc`, `separate_colour_plane_vps_flag`, `pic_width_vps_in_luma_samples`, `pic_height_vps_in_luma_samples`, `bit_depth_vps_luma_minus8`, `bit_depth_vps_chroma_minus8`, `conf_win_vps_left_offset`, `conf_win_vps_right_offset`, `conf_win_vps_top_offset` and `conf_win_vps_bottom_offset` respectively, of the `repFormatIdx`-th `rep_format()` syntax structure in the active VPS.

It is a requirement of bitstream conformance that, when present, the value of `chroma_format_idc`, `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `bit_depth_luma_minus8` or `bit_depth_chroma_minus8` shall be less than or equal to `chroma_format_vps_idc`, `pic_width_vps_in_luma_samples`, `pic_height_vps_in_luma_samples`, `bit_depth_vps_luma_minus8`, or `bit_depth_vps_chroma_minus8`, respectively, of the `vps_rep_format_idx[j]`-th `rep_format()` syntax structure in the active VPS, where `j` is equal to `LayerIdxInVps[layerIdCurr]`.

sps_max_dec_pic_buffering_minus1[i] plus 1 specifies the maximum required size of the decoded picture buffer for the CVS in units of picture storage buffers when `HighestTid` is equal to `i`. The value of `sps_max_dec_pic_buffering_minus1[i]` shall be in the range of 0 to `MaxDpbSize - 1`, inclusive, where `MaxDpbSize` is as specified in clause A.4. When `i` is greater than 0, `sps_max_dec_pic_buffering_minus1[i]` shall be greater than or equal to `sps_max_dec_pic_buffering_minus1[i - 1]`. The value of `sps_max_dec_pic_buffering_minus1[i]` shall be less than or equal to `vps_max_dec_pic_buffering_minus1[i]` for each value of `i`. When `sps_max_dec_pic_buffering_minus1[i]` is not present for `i` in the range of 0 to `sps_max_sub_layers_minus1 - 1`, inclusive, due to `sps_sub_layer_ordering_info_present_flag` being equal to 0, it is inferred to be equal to `sps_max_dec_pic_buffering_minus1[sps_max_sub_layers_minus1]`.

When `sps_max_dec_pic_buffering_minus1[i]` is not present for `i` in the range of 0 to `sps_max_sub_layers_minus1`, inclusive, due to `MultiLayerExtSpsFlag` being equal to 1, for a layer that refers to the SPS and has `nuh_layer_id` equal to `currLayerId`, the value of `sps_max_dec_pic_buffering_minus1[i]` is inferred to be equal to `max_vps_dec_pic_buffering_minus1[TargetOlsIdx][layerIdx][i]` of the active VPS, where `layerIdx` is equal to the value such that `LayerSetLayerIdList[TargetDecLayerSetIdx][layerIdx]` is equal to `currLayerId`.

sps_infer_scaling_list_flag equal to 1 specifies that the syntax elements of the scaling list data syntax structure of the SPS are inferred to be equal to those of the SPS that is active for the layer with `nuh_layer_id` equal to `sps_scaling_list_ref_layer_id`. **sps_infer_scaling_list_flag** equal to 0 specifies that the syntax elements of the scaling list data syntax structure are not inferred. When not present, the value of `sps_infer_scaling_list_flag` is inferred to be 0.

sps_scaling_list_ref_layer_id specifies the value of the `nuh_layer_id` of the layer for which the active SPS is associated with the same scaling list data as the current SPS. The value of `sps_scaling_list_ref_layer_id` shall be in the range of 0 to 62, inclusive.

When `vps_base_layer_internal_flag` is equal to 0, it is a requirement of bitstream conformance that the value of `sps_scaling_list_ref_layer_id`, when present, shall be greater than 0.

It is a requirement of bitstream conformance that, when an SPS with `nuh_layer_id` equal to `nuhLayerIdA` is active for a layer with `nuh_layer_id` equal to `nuhLayerIdB` and `sps_infer_scaling_list_flag` in the SPS is equal to 1, `sps_infer_scaling_list_flag` shall be equal to 0 for the SPS that is active for the layer with `nuh_layer_id` equal to `sps_scaling_list_ref_layer_id`.

It is a requirement of bitstream conformance that, when an SPS with `nuh_layer_id` equal to `nuhLayerIdA` is active for a layer with `nuh_layer_id` equal to `nuhLayerIdB` and `sps_infer_scaling_list_flag` in the SPS equal to 1, the layer with `nuh_layer_id` equal to `sps_scaling_list_ref_layer_id` shall be a reference layer of the layer with `nuh_layer_id` equal to `nuhLayerIdB`.

It is a requirement of bitstream conformance that, when an SPS is active for a layer with `sps_infer_scaling_list_flag` in the SPS is equal to 1, `scaling_list_enabled_flag` shall be equal to 1 for the SPS that is active for the layer with `nuh_layer_id` equal to `sps_scaling_list_ref_layer_id`.

F.7.4.3.2.2 Sequence parameter set range extension semantics

The specifications in clause 7.4.3.2.2 apply.

F.7.4.3.2.3 Sequence parameter set screen content coding extension semantics

The specifications in clause 7.4.3.2.3 apply.

F.7.4.3.2.4 Sequence parameter set multilayer extension semantics

inter_view_mv_vert_constraint_flag equal to 1 indicates that vertical component of motion vectors used for inter-layer prediction are constrained in the layers for which this SPS RBSP is the active SPS RBSP. When `inter_view_mv_vert_constraint_flag` is equal to 1, the vertical component of the motion vectors used for inter-layer prediction shall be less than or equal to 56 in units of luma samples. When `inter_view_mv_vert_constraint_flag` is equal to 0, no constraint on the vertical component of the motion vectors used for inter-layer prediction is signalled by this flag. When not present, the value of `inter_view_mv_vert_constraint_flag` is inferred to be equal to 0.

F.7.4.3.3 Picture parameter set RBSP semantics

F.7.4.3.3.1 General picture parameter set RBSP semantics

The specifications in clause 7.4.3.3.1 apply with the replacement of the semantics of `pps_scaling_list_data_present_flag` as follows:

pps_scaling_list_data_present_flag equal to 1 specifies that the scaling list data used for the pictures referring to the PPS are derived based on the scaling lists specified by the active SPS and the scaling lists specified by the PPS. `pps_scaling_list_data_present_flag` equal to 0 specifies that the scaling list data used for the pictures referring to the PPS are inferred to be equal to those specified by the active SPS (when `pps_infer_scaling_list_flag` is equal to 0) or is specified by `pps_scaling_list_ref_layer_id` (when `pps_infer_scaling_list_flag` is equal to 1). When `scaling_list_enabled_flag` is equal to 0, the value of `pps_scaling_list_data_present_flag` shall be equal to 0. When `scaling_list_enabled_flag` is equal to 1, `sps_scaling_list_data_present_flag` is equal to 0, `pps_scaling_list_data_present_flag` is equal to 0 and `pps_infer_scaling_list_flag` is equal to 0, the default scaling list data are used to derive the array `ScalingFactor` as specified in clause 7.4.5.

F.7.4.3.3.2 Picture parameter set range extension semantics

The specifications in clause 7.4.3.3.2 apply.

F.7.4.3.3.3 Picture parameter set screen content coding extension semantics

The specifications in clause 7.4.3.3.3 apply.

F.7.4.3.3.4 Picture parameter set multilayer extension semantics

poc_reset_info_present_flag equal to 0 specifies that the syntax element **poc_reset_idc** is not present in the slice segment headers of the slices referring to the PPS. **poc_reset_info_present_flag** equal to 1 specifies that the syntax element **poc_reset_idc** is present in the slice segment headers of the slices referring to the PPS. When not present, the value of **poc_reset_info_present_flag** is inferred to be equal to 0.

pps_infer_scaling_list_flag equal to 1 specifies that the syntax elements of the scaling list data syntax structure of the PPS are inferred to be equal to those of the PPS that is active for the layer with **nuh_layer_id** equal to **pps_scaling_list_ref_layer_id**. **pps_infer_scaling_list_flag** equal to 0 specifies that the syntax elements of the scaling list data syntax structure of the PPS are not inferred. When **scaling_list_enabled_flag** is equal to 0, **nuh_layer_id** of the layer referring to the PPS is equal to 0 or **pps_scaling_list_data_present_flag** is equal to 1, **pps_infer_scaling_list_flag** shall be equal to 0. When not present, the value of **pps_infer_scaling_list_flag** is inferred to be 0.

pps_scaling_list_ref_layer_id specifies the value of **nuh_layer_id** of the layer for which the active PPS has the same scaling list data as the current PPS.

The value of **pps_scaling_list_ref_layer_id** shall be in the range of 0 to 62, inclusive.

When **vps_base_layer_internal_flag** is equal to 0, it is a requirement of bitstream conformance that **pps_scaling_list_ref_layer_id**, when present, shall be greater than 0. It is a requirement of bitstream conformance that, when a PPS with **nuh_layer_id** equal to **nuhLayerIdA** is active for a layer with **nuh_layer_id** equal to **nuhLayerIdB** and **pps_infer_scaling_list_flag** in the PPS is equal to 1, **pps_infer_scaling_list_flag** shall be equal to 0 for the PPS that is active for the layer with **nuh_layer_id** equal to **pps_scaling_list_ref_layer_id**.

It is a requirement of bitstream conformance that, when a PPS with **nuh_layer_id** equal to **nuhLayerIdA** is active for a layer with **nuh_layer_id** equal to **nuhLayerIdB** and **pps_infer_scaling_list_flag** in the PPS equal to 1, the layer with **nuh_layer_id** equal to **pps_scaling_list_ref_layer_id** shall be a reference layer of the layer with **nuh_layer_id** equal to **nuhLayerIdB**.

It is a requirement of bitstream conformance that, when a PPS is active for a layer with **pps_infer_scaling_list_flag** in the PPS equal to 1, **scaling_list_enabled_flag** shall be equal to 1 for the SPS that is active for the layer with **nuh_layer_id** equal to **pps_scaling_list_ref_layer_id**.

num_ref_loc_offsets specifies the number of reference layer location offsets that are present in the PPS. The value of **num_ref_loc_offsets** shall be in the range of 0 to **vps_max_layers_minus1**, inclusive.

ref_loc_offset_layer_id[i] specifies the **nuh_layer_id** value for which the *i*-th reference layer location offset parameters are specified.

NOTE – **ref_loc_offset_layer_id[i]** need not be among the direct reference layers, for example when the spatial correspondence of an auxiliary picture to its associated primary picture is specified.

The *i*-th reference layer location offset parameters consist of the *i*-th scaled reference layer offset parameters, the *i*-th reference region offset parameters and the *i*-th resampling phase set parameters.

scaled_ref_layer_offset_present_flag[i] equal to 1 specifies that the *i*-th scaled reference layer offset parameters are present in the PPS. **scaled_ref_layer_offset_present_flag[i]** equal to 0 specifies that the *i*-th scaled reference layer offset parameters are not present in the PPS. When not present, the value of **scaled_ref_layer_offset_present_flag[i]** is inferred to be equal to 0.

The *i*-th scaled reference layer offset parameters specify the spatial correspondence of a picture referring to this PPS relative to the reference region in a decoded picture with **nuh_layer_id** equal to **ref_loc_offset_layer_id[i]**.

scaled_ref_layer_left_offset[ref_loc_offset_layer_id[i]] specifies the horizontal offset between the sample in the current picture that is collocated with the top-left luma sample of the reference region in a decoded picture with **nuh_layer_id** equal to **ref_loc_offset_layer_id[i]** and the top-left luma sample of the current picture in units of subWC luma samples, where subWC is equal to the SubWidthC of the picture that refers to this PPS. The value of **scaled_ref_layer_left_offset[ref_loc_offset_layer_id[i]]** shall be in the range of -2^{14} to $2^{14} - 1$, inclusive. When not present, the value of **scaled_ref_layer_left_offset[ref_loc_offset_layer_id[i]]** is inferred to be equal to 0.

scaled_ref_layer_top_offset[ref_loc_offset_layer_id[i]] specifies the vertical offset between the sample in the current picture that is collocated with the top-left luma sample of the reference region in a decoded picture with **nuh_layer_id** equal to **ref_loc_offset_layer_id[i]** and the top-left luma sample of the current picture in units of subHC luma samples, where subHC is equal to the SubHeightC of the picture that refers to this PPS. The value of **scaled_ref_layer_top_offset[ref_loc_offset_layer_id[i]]** shall be in the range of -2^{14} to $2^{14} - 1$, inclusive. When not present, the value of **scaled_ref_layer_top_offset[ref_loc_offset_layer_id[i]]** is inferred to be equal to 0.

scaled_ref_layer_right_offset[ref_loc_offset_layer_id[i]] specifies the horizontal offset between the sample in the current picture that is collocated with the bottom-right luma sample of the reference region in a decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] and the bottom-right luma sample of the current picture in units of subWC luma samples, where subWC is equal to the SubWidthC of the picture that refers to this PPS. The value of scaled_ref_layer_right_offset[ref_loc_offset_layer_id[i]] shall be in the range of -2^{14} to $2^{14} - 1$, inclusive. When not present, the value of scaled_ref_layer_right_offset[ref_loc_offset_layer_id[i]] is inferred to be equal to 0.

scaled_ref_layer_bottom_offset[ref_loc_offset_layer_id[i]] specifies the vertical offset between the sample in the current picture that is collocated with the bottom-right luma sample of the reference region in a decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] and the bottom-right luma sample of the current picture in units of subHC luma samples, where subHC is equal to the SubHeightC of the picture that refers to this PPS. The value of scaled_ref_layer_bottom_offset[ref_loc_offset_layer_id[i]] shall be in the range of -2^{14} to $2^{14} - 1$, inclusive. When not present, the value of scaled_ref_layer_bottom_offset[ref_loc_offset_layer_id[i]] is inferred to be equal to 0.

Let currTopLeftSample, currBotRightSample, colRefRegionTopLeftSample and colRefRegionBotRightSample be the top-left luma sample of the current picture, the bottom-right luma sample of the current picture, the sample in the current picture that is collocated with the top-left luma sample of the reference region in a decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i], and the sample in the current picture that is collocated with the bottom-right luma sample of the reference region in the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i], respectively.

When the value of scaled_ref_layer_left_offset[ref_loc_offset_layer_id[i]] is greater than 0, colRefRegionTopLeftSample is located to the right of currTopLeftSample. When the value of scaled_ref_layer_left_offset[ref_loc_offset_layer_id[i]] is less than 0, colRefRegionTopLeftSample is located to the left of currTopLeftSample.

When the value of scaled_ref_layer_top_offset[ref_loc_offset_layer_id[i]] is greater than 0, colRefRegionTopLeftSample is located below currTopLeftSample. When the value of scaled_ref_layer_top_offset[ref_loc_offset_layer_id[i]] is less than 0, colRefRegionTopLeftSample is located above currTopLeftSample.

When the value of scaled_ref_layer_right_offset[ref_loc_offset_layer_id[i]] is greater than 0, colRefRegionBotRightSample is located to the left of currBotRightSample. When the value of scaled_ref_layer_right_offset[ref_loc_offset_layer_id[i]] is less than 0, colRefRegionTopLeftSample is located to the right of currBotRightSample.

When the value of scaled_ref_layer_bottom_offset[ref_loc_offset_layer_id[i]] is greater than 0, colRefRegionBotRightSample is located above currBotRightSample. When the value of scaled_ref_layer_bottom_offset[ref_loc_offset_layer_id[i]] is less than 0, colRefRegionTopLeftSample is located below currBotRightSample.

ref_region_offset_present_flag[i] equal to 1 specifies that the i-th reference region offset parameters are present in the PPS. ref_region_offset_present_flag[i] equal to 0 specifies that the i-th reference region offset parameters are not present in the PPS. When not present, the value of ref_region_offset_present_flag[i] is inferred to be equal to 0.

The i-th reference region offset parameters specify the spatial correspondence of the reference region in the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] relative to the same decoded picture.

ref_region_left_offset[ref_loc_offset_layer_id[i]] specifies the horizontal offset between the top-left luma sample of the reference region in the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] and the top-left luma sample of the same decoded picture in units of subWC luma samples, where subWC is equal to the SubWidthC of the layer with nuh_layer_id equal to ref_loc_offset_layer_id[i]. The value of ref_region_left_offset[ref_loc_offset_layer_id[i]] shall be in the range of -2^{14} to $2^{14} - 1$, inclusive. When not present, the value of ref_region_left_offset[ref_loc_offset_layer_id[i]] is inferred to be equal to 0.

ref_region_top_offset[ref_loc_offset_layer_id[i]] specifies the vertical offset between the top-left luma sample of the reference region in the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] and the top-left luma sample of the same decoded picture in units of subHC luma samples, where subHC is equal to the SubHeightC of the layer with nuh_layer_id equal to ref_loc_offset_layer_id[i]. The value of ref_region_top_offset[ref_loc_offset_layer_id[i]] shall be in the range of -2^{14} to $2^{14} - 1$, inclusive. When not present, the value of ref_region_top_offset[ref_loc_offset_layer_id[i]] is inferred to be equal to 0.

ref_region_right_offset[ref_loc_offset_layer_id[i]] specifies the horizontal offset between the bottom-right luma sample of the reference region in the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] and the bottom-right luma sample of the same decoded picture in units of subWC luma samples, where subWC is equal to the SubWidthC of the layer with nuh_layer_id equal to ref_loc_offset_layer_id[i]. The value of ref_layer_right_offset[ref_loc_offset_layer_id[i]] shall be in the range of -2^{14} to $2^{14} - 1$, inclusive. When not present, the value of ref_region_right_offset[ref_loc_offset_layer_id[i]] is inferred to be equal to 0.

ref_region_bottom_offset[ref_loc_offset_layer_id[i]] specifies the vertical offset between the bottom-right luma sample of the reference region in the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] and the bottom-right luma sample of the same decoded picture in units of subHC luma samples, where subHC is equal to the SubHeightC of the layer with nuh_layer_id equal to ref_loc_offset_layer_id[i]. The value of ref_layer_bottom_offset[ref_loc_offset_layer_id[i]] shall be in the range of -2^{14} to $2^{14} - 1$, inclusive. When not present, the value of ref_region_bottom_offset[ref_loc_offset_layer_id[i]] is inferred to be equal to 0.

Let refPicTopLeftSample, refPicBotRightSample, refRegionTopLeftSample and refRegionBotRightSample be the top-left luma sample of the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i], the bottom-right luma sample of the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i], the top-left luma sample of the reference region in the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] and the bottom-right luma sample of the reference region in the decoded picture with nuh_layer_id equal to ref_loc_offset_layer_id[i], respectively.

When the value of ref_region_left_offset[ref_loc_offset_layer_id[i]] is greater than 0, refRegionTopLeftSample is located to the right of refPicTopLeftSample. When the value of ref_region_left_offset[ref_loc_offset_layer_id[i]] is less than 0, refRegionTopLeftSample is located to the left of refPicTopLeftSample.

When the value of ref_region_top_offset[ref_loc_offset_layer_id[i]] is greater than 0, refRegionTopLeftSample is located below refPicTopLeftSample. When the value of ref_region_top_offset[ref_loc_offset_layer_id[i]] is less than 0, refRegionTopLeftSample is located above refPicTopLeftSample.

When the value of ref_region_right_offset[ref_loc_offset_layer_id[i]] is greater than 0, refRegionBotRightSample is located to the left of refPicBotRightSample. When the value of ref_region_right_offset[ref_loc_offset_layer_id[i]] is less than 0, refRegionBotRightSample is located to the right of refPicBotRightSample.

When the value of ref_region_bottom_offset[ref_loc_offset_layer_id[i]] is greater than 0, refRegionBotRightSample is located above refPicBotRightSample. When the value of ref_region_bottom_offset[ref_loc_offset_layer_id[i]] is less than 0, refRegionBotRightSample is located below refPicBotRightSample.

resample_phase_set_present_flag[i] equal to 1 specifies that the i-th resampling phase set is present in the PPS. resample_phase_set_present_flag[i] equal to 0 specifies that the i-th resampling phase set is not present in the PPS. When not present, the value of resample_phase_set_present_flag[i] is inferred to be equal to 0.

The i-th resampling phase set specifies the phase offsets used in resampling process of the direct reference layer picture with nuh_layer_id equal to ref_loc_offset_layer_id[i]. When the layer specified by ref_loc_offset_layer_id[i] is not a direct reference layer of the current layer, the values of the syntax elements phase_hor_luma[ref_loc_offset_layer_id[i]], phase_ver_luma[ref_loc_offset_layer_id[i]], phase_hor_chroma_plus8[ref_loc_offset_layer_id[i]] and phase_ver_chroma_plus8[ref_loc_offset_layer_id[i]] are unspecified and shall be ignored by decoders.

phase_hor_luma[ref_loc_offset_layer_id[i]] specifies the luma phase shift in the horizontal direction used in the resampling process of the direct reference layer picture with nuh_layer_id equal to ref_loc_offset_layer_id[i]. The value of phase_hor_luma[ref_loc_offset_layer_id[i]] shall be in the range of 0 to 31, inclusive. When not present, the value of phase_hor_luma[ref_loc_offset_layer_id[i]] is inferred to be equal to 0.

phase_ver_luma[ref_loc_offset_layer_id[i]] specifies the luma phase shift in the vertical direction used in the resampling of the direct reference layer picture with nuh_layer_id equal to ref_loc_offset_layer_id[i]. The value of phase_ver_luma[ref_loc_offset_layer_id[i]] shall be in the range of 0 to 31, inclusive. When not present, the value of phase_ver_luma[ref_loc_offset_layer_id[i]] is inferred to be equal to 0.

phase_hor_chroma_plus8[ref_loc_offset_layer_id[i]] minus 8 specifies the chroma phase shift in the horizontal direction used in the resampling of the direct reference layer picture with nuh_layer_id equal to ref_loc_offset_layer_id[i]. The value of phase_hor_chroma_plus8[ref_loc_offset_layer_id[i]] shall be in the range of 0 to 63, inclusive. When not present, the value of phase_hor_chroma_plus8[ref_loc_offset_layer_id[i]] is inferred to be equal to 8.

phase_ver_chroma_plus8[ref_loc_offset_layer_id[i]] minus 8 specifies the chroma phase shift in the vertical direction used in the resampling process of the direct reference layer picture with nuh_layer_id equal to ref_loc_offset_layer_id[i]. The value of phase_ver_chroma_plus8[ref_loc_offset_layer_id[i]] shall be in the range of 0 to 63, inclusive. When not present, the value of phase_ver_chroma_plus8[ref_loc_offset_layer_id[i]] is inferred as follows:

- If chroma_format_idc is equal to 3 (4:4:4 chroma format), the value of phase_ver_chroma_plus8[ref_loc_offset_layer_id[i]] is inferred to be equal to 8.
- Otherwise, the value of phase_ver_chroma_plus8[ref_loc_offset_layer_id[i]] is inferred to be equal to $(4 * \text{scaledRefRegHeight} + \text{refRegHeight} / 2) / \text{refRegHeight} + 4$, where the value of scaledRefRegHeight is equal to the value of ScaledRefRegionHeightInSamplesY derived for the direct reference layer picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] of the picture that refers to this PPS, and the value of refRegHeight is equal to RefLayerRegionHeightInSamplesY derived for the direct reference layer picture with nuh_layer_id equal to ref_loc_offset_layer_id[i] of the picture that refers to this PPS.

colour_mapping_enabled_flag equal to 1 specifies the colour mapping process may be applied to the inter-layer reference pictures for the coded pictures referring to the PPS. **colour_mapping_enabled_flag** equal to 0 specifies that the colour mapping process is not applied to the inter-layer reference pictures for the coded pictures referring to the PPS. When not present, the value of **colour_mapping_enabled_flag** is inferred to be equal to 0.

It is a requirement of bitstream conformance that, when **pps_pic_parameter_set_id** is greater than or equal to 8, **colour_mapping_enabled_flag** shall be equal to 0.

F.7.4.3.3.5 General colour mapping table semantics

num_cm_ref_layers_minus1 specifies the number of the following **cm_ref_layer_id[i]** syntax elements. The value of **num_cm_ref_layers_minus1** shall be in the range of 0 to 61, inclusive.

cm_ref_layer_id[i] specifies the **nuh_layer_id** value of the associated direct reference layer picture for which the colour mapping table is specified.

cm_octant_depth specifies the maximal split depth of the colour mapping table. In bitstreams conforming to this version of this Specification, the value of **cm_octant_depth** shall be in the range of 0 to 1, inclusive. Other values for **cm_octant_depth** are reserved for future use by ITU-T | ISO/IEC.

The variable **OctantNumC** is derived as follows:

$$\text{OctantNumC} = 1 \ll \text{cm_octant_depth} \quad (\text{F-41})$$

cm_y_part_num_log2 specifies the number of partitions of the smallest colour mapping table octant for the luma component. In bitstreams conforming to this version of this Specification, the value of $(\text{cm_y_part_num_log2} + \text{cm_octant_depth})$ shall be in the range of 0 to 3, inclusive. Other values for $(\text{cm_y_part_num_log2} + \text{cm_octant_depth})$ are reserved for future use by ITU-T | ISO/IEC.

The variables **OctantNumY** and **PartNumY** are derived as follows:

$$\text{OctantNumY} = 1 \ll (\text{cm_octant_depth} + \text{cm_y_part_num_log2}) \quad (\text{F-42})$$

$$\text{PartNumY} = 1 \ll \text{cm_y_part_num_log2} \quad (\text{F-43})$$

luma_bit_depth_cm_input_minus8 specifies the sample bit depth of the input luma component of the colour mapping process. The variable **BitDepthCmInputY** is derived as follows:

$$\text{BitDepthCmInputY} = 8 + \text{luma_bit_depth_cm_input_minus8} \quad (\text{F-44})$$

It is a requirement of bitstream conformance that the value of **BitDepthCmInputY** shall be equal to the bit depth of the luma component of any reference layer with **nuh_layer_id** equal to one of the **cm_ref_layer_id[i]**, for all **i** in the range of 0 to **num_cm_ref_layers_minus1**, inclusive.

chroma_bit_depth_cm_input_minus8 specifies the sample bit depth of the input chroma components of the colour mapping process. The variable **BitDepthCmInputC** is derived as follows:

$$\text{BitDepthCmInputC} = 8 + \text{chroma_bit_depth_cm_input_minus8} \quad (\text{F-45})$$

It is a requirement of bitstream conformance that the value of **BitDepthCmInputC** shall be equal to the bit depth of the chroma components of any reference layer with **nuh_layer_id** equal to one of the **cm_ref_layer_id[i]**, for all **i** in the range of 0 to **num_cm_ref_layers_minus1**, inclusive.

luma_bit_depth_cm_output_minus8 specifies the sample bit depth of the output luma component of the colour mapping process. The variable **BitDepthCmOutputY** is derived as follows:

$$\text{BitDepthCmOutputY} = 8 + \text{luma_bit_depth_cm_output_minus8} \quad (\text{F-46})$$

It is a requirement of bitstream conformance that the value of **BitDepthCmOutputY** shall be greater than or equal to **BitDepthCmInputY** and less than or equal to the bit depth of the luma components of any picture that refers to this PPS.

chroma_bit_depth_cm_output_minus8 specifies the sample bit depth of the output chroma components of the colour mapping process. The variable **BitDepthCmOutputC** is derived as follows:

$$\text{BitDepthCmOutputC} = 8 + \text{chroma_bit_depth_cm_output_minus8} \quad (\text{F-47})$$

It is a requirement of bitstream conformance that the value of **BitDepthCmOutputC** shall be greater than or equal to **BitDepthCmInputC** and less than or equal to the bit depth of the chroma components of any picture that refers to this PPS.

cm_res_quant_bits specifies the number of least significant bits to be added to the colour mapping coefficient residual values **res_coeff_q** and **res_coeff_r**.

cm_delta_flc_bits_minus1 specifies the delta value used to derive the number of bits used to code the syntax element **res_coeff_r**. The variable **CMResLSBits** is set equal to $\text{Max}(0, (10 + \text{BitDepthCmInputY} - \text{BitDepthCmOutputY} - \text{cm_res_quant_bits} - (\text{cm_delta_flc_bits_minus1} + 1)))$.

cm_adapt_threshold_u_delta specifies the partitioning threshold of the Cb component used in colour mapping process. When not present, the value of **cm_adapt_threshold_u_delta** is inferred to be equal to 0. The value of **cm_adapt_threshold_u_delta** shall be in the range of $-2^{\text{BitDepthCmInputC}-1}$ to $2^{\text{BitDepthCmInputC}-1}-1$, inclusive.

The variable **CMThreshU** is derived as follows:

$$\text{CMThreshU} = \text{cm_adapt_threshold_u_delta} + (1 \ll (\text{BitDepthCmInputC} - 1)) \quad (\text{F-48})$$

cm_adapt_threshold_v_delta specifies the partitioning threshold of the Cr component used in colour mapping process. When not present, the value of **cm_adapt_threshold_v_delta** is inferred to be equal to 0. The value of **cm_adapt_threshold_v_delta** shall be in the range of $-2^{\text{BitDepthCmInputC}-1}$ to $2^{\text{BitDepthCmInputC}-1}-1$, inclusive.

The variable **CMThreshV** is derived as follows:

$$\text{CMThreshV} = \text{cm_adapt_threshold_v_delta} + (1 \ll (\text{BitDepthCmInputC} - 1)) \quad (\text{F-49})$$

F.7.4.3.3.6 Colour mapping octants semantics

split_octant_flag equal to 1 specifies that the current colour mapping octant is further split into eight octants with half length in each of the three dimensions. **split_octant_flag** equal to 0 specifies that the current colour mapping octant is not further split into eight octants. When not present, the value of **split_octant_flag** is inferred to be equal to 0.

coded_res_flag[**idxShiftY**][**idxCb**][**idxCr**][**j**] equal to 1 specifies that the residuals for the **j**-th colour mapping coefficients of the octant with octant index equal to (**idxShiftY**, **idxCb**, **idxCr**) are present. **coded_res_flag**[**idxShiftY**][**idxCb**][**idxCr**][**j**] equal to 0 specifies that the residuals for the **j**-th colour mapping coefficients of the octant with octant index equal to (**idxShiftY**, **idxCb**, **idxCr**) are not present. When not present, the value of **coded_res_flag**[**idxShiftY**][**idxCb**][**idxCr**][**j**] is inferred to be equal to 0.

res_coeff_q[**idxShiftY**][**idxCb**][**idxCr**][**j**][**c**] specifies the quotient of the residual for the **j**-th colour mapping coefficient of the **c**-th colour component of the octant with octant index equal to (**idxShiftY**, **idxCb**, **idxCr**). When not present, the value of **res_coeff_q**[**idxShiftY**][**idxCb**][**idxCr**][**j**][**c**] is inferred to be equal to 0.

res_coeff_r[**idxShiftY**][**idxCb**][**idxCr**][**j**][**c**] specifies the remainder of the residual for the **j**-th colour mapping coefficient of the **c**-th colour component of the octant with octant index equal to (**idxShiftY**, **idxCb**, **idxCr**). The number of bits used to code **res_coeff_r** is equal to **CMResLSBits**. If **CMResLSBits** is equal to 0, **res_coeff_r** is not present. When not present, the value of **res_coeff_r**[**idxShiftY**][**idxCb**][**idxCr**][**j**][**c**] is inferred to be equal to 0.

res_coeff_s[**idxShiftY**][**idxCb**][**idxCr**][**j**][**c**] specifies the sign of the residual for the **j**-th colour mapping coefficient of the **c**-th colour component of the octant with octant index equal to (**idxShiftY**, **idxCb**, **idxCr**). When not present, the value of **res_coeff_s**[**idxShiftY**][**idxCb**][**idxCr**][**j**][**c**] is inferred to be equal to 0.

The variables **cmResCoeff**[**idxShiftY**][**idxCb**][**idxCr**][**j**][**c**], with **idxShiftY** in the range of 0 to **OctantNumY** - 1, inclusive, **idxCb** and **idxCr** both in the range of 0 to **OctantNumC** - 1, inclusive, **j** in the range of 0 to 3, inclusive, and **c** in the range of 0 to 2, inclusive, are derived as follows:

$$\begin{aligned} \text{cmResCoeff}[\text{idxShiftY}][\text{idxCb}][\text{idxCr}][j][c] = \\ (1 - 2 * \text{res_coeff_s}[\text{idxShiftY}][\text{idxCb}][\text{idxCr}][j][c]) * \\ ((\text{res_coeff_q}[\text{idxShiftY}][\text{idxCb}][\text{idxCr}][j][c] \ll \text{CMResLSBits}) + \\ \text{res_coeff_r}[\text{idxShiftY}][\text{idxCb}][\text{idxCr}][j][c]) \ll \text{cm_res_quant_bits}) \end{aligned} \quad (\text{F-50})$$

The colour mapping coefficients **LutY**[**idxY**][**idxCb**][**idxCr**][**j**], **LutCb**[**idxY**][**idxCb**][**idxCr**][**j**], **LutCr**[**idxY**][**idxCb**][**idxCr**][**j**] with **idxY** in the range of 0 and **OctantNumY** - 1, inclusive, **idxCb** in the range of 0 and **OctantNumC** - 1, inclusive, **idxCr** in the range of 0 and **OctantNumC** - 1, inclusive, and **j** in the range of 0 and 3, inclusive, are derived as follows:

$$\begin{aligned} \text{if}(\text{idxY} == 0) \{ \\ \quad \text{predY}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] = (j == 0) ? 1024 : 0 \\ \quad \text{predCb}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] = (j == 1) ? 1024 : 0 \\ \quad \text{predCr}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] = (j == 2) ? 1024 : 0 \\ \} \text{ else } \{ \\ \quad \text{predY}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] = \text{LutY}[\text{idxY} - 1][\text{idxCb}][\text{idxCr}][j] \\ \quad \text{predCb}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] = \text{LutCb}[\text{idxY} - 1][\text{idxCb}][\text{idxCr}][j] \\ \quad \text{predCr}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] = \text{LutCr}[\text{idxY} - 1][\text{idxCb}][\text{idxCr}][j] \\ \} \end{aligned} \quad (\text{F-51})$$

$$\begin{aligned}
\text{LutY}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] &= \\
&(\text{cmResCoeff}[\text{idxY}][\text{idxCb}][\text{idxCr}][j][0]) + \\
&\text{predY}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] \\
\text{LutCb}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] &= \\
&(\text{cmResCoeff}[\text{idxY}][\text{idxCb}][\text{idxCr}][j][1]) + \\
&\text{predCb}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] \\
\text{LutCr}[\text{idxY}][\text{idxCb}][\text{idxCr}][j] &= \\
&(\text{cmResCoeff}[\text{idxY}][\text{idxCb}][\text{idxCr}][j][2]) + \\
&\text{predCr}[\text{idxY}][\text{idxCb}][\text{idxCr}][j]
\end{aligned}$$

It is a requirement of bitstream conformance that the values of $\text{LutY}[\text{idxY}][\text{idxCb}][\text{idxCr}][i]$, $\text{LutCb}[\text{idxY}][\text{idxCb}][\text{idxCr}][i]$ and $\text{LutCr}[\text{idxY}][\text{idxCb}][\text{idxCr}][i]$ shall be in the range of -2^{11} to $2^{11}-1$, inclusive.

NOTE – When BitDepthCmInputC is not equal to BitDepthCmInputY , the encoder should select values of $\text{LutY}[\text{idxY}][\text{idxCb}][\text{idxCr}][1]$, $\text{LutY}[\text{idxY}][\text{idxCb}][\text{idxCr}][2]$, $\text{LutCb}[\text{idxY}][\text{idxCb}][\text{idxCr}][0]$ and $\text{LutCr}[\text{idxY}][\text{idxCb}][\text{idxCr}][0]$ that compensate for the bit depth difference.

F.7.4.3.4 Supplemental enhancement information RBSP semantics

The specifications in clause 7.4.3.4 apply.

F.7.4.3.5 Access unit delimiter RBSP semantics

The specifications in clause 7.4.3.5 apply.

F.7.4.3.6 End of sequence RBSP semantics

The specifications in clause 7.4.3.6 apply with the following additions:

When included in a NAL unit with nuh_layer_id nuhLayerId , the end of sequence RBSP specifies that the next picture having nuh_layer_id equal to nuhLayerId or $\text{IdPredictedLayer}[\text{nuhLayerId}][i]$ for any value of i in the range of 0 to $\text{NumPredictedLayers}[\text{nuhLayerId}] - 1$, inclusive, following the current access unit in the bitstream in decoding order (if any) is an IRAP picture with NoRasOutputFlag equal to 1 and with nuh_layer_id equal to nuhLayerId .

F.7.4.3.7 End of bitstream RBSP semantics

The specifications in clause 7.4.3.7 apply.

F.7.4.3.8 Filler data RBSP semantics

The specifications in clause 7.4.3.8 apply.

F.7.4.3.9 Slice segment layer RBSP semantics

The specifications in clause 7.4.3.9 apply.

F.7.4.3.10 RBSP slice segment trailing bits semantics

The specifications in clause 7.4.3.10 apply.

F.7.4.3.11 RBSP trailing bits semantics

The specifications in clause 7.4.3.11 apply.

F.7.4.3.12 Byte alignment semantics

The specifications in clause 7.4.3.12 apply.

F.7.4.4 Profile, tier and level semantics

The specifications in clause 7.4.4 apply with the replacement of each reference to "Annex A" with a reference to "Annex A, clause G.11 or clause H.11" and with the following additions and modifications:

The variable offsetVal is set equal to 0 and the variable $\text{VpsProfileTierLevel}[i]$ is derived according to the following ordered steps:

1. $\text{VpsProfileTierLevel}[0]$ is set equal to the $\text{profile_tier_level}()$ syntax structure in the base VPS (i.e., in the VPS but not in the VPS extension syntax structure $\text{vps_extension}()$) and offsetVal is set equal to 1.

2. When `vps_max_layers_minus1` is greater than 0 and `vps_base_layer_internal_flag` is equal to 1 `VpsProfileTierLevel[offsetVal]` is set equal to the first `profile_tier_level()` syntax structure in the VPS extension, and `offsetVal` is incremented by 1.
3. For `j` in the range of 0 to $(\text{vps_num_profile_tier_level_minus1} - (\text{vps_base_layer_internal_flag} ? 2 : 1))$, inclusive, `VpsProfileTierLevel[offsetVal + j]` is set equal to the `j`-th `profile_tier_level()` syntax structure signalled after the syntax element `vps_num_profile_tier_level_minus1` in the VPS extension.

If `vps_base_layer_internal_flag` is equal to 0, all bits in the `profile_tier_level()` syntax structure `VpsProfileTierLevel[0]` shall be equal to 0 and decoders shall ignore the syntax structure `VpsProfileTierLevel[0]`. Otherwise, the semantics of the `profile_tier_level()` syntax structure `VpsProfileTierLevel[0]` are specified by the remaining part of the current clause.

The scope to which the `profile_tier_level()` syntax structure applies is specified as follows:

- If the `profile_tier_level()` syntax structure is included in an active SPS for the base layer or is the `profile_tier_level()` syntax structure `VpsProfileTierLevel[0]`, it applies to the OLS containing all layers in the bitstream but with only the base layer being the output layer.
- Otherwise, if the `profile_tier_level()` syntax structure is included in an active SPS for an independent non-base layer with `nuh_layer_id` equal to `layerId`, it applies to the output bitstream of the independent non-base layer rewriting process of clause F.10.2 with the input variables `assignedBaseLayerId` equal to `layerId` and `tIdTarget` equal to 6.
- Otherwise, if all of the following conditions are true, the `profile_tier_level()` syntax structure `VpsProfileTierLevel[profile_tier_level_idx[olsIdx][0]]` applies to the output bitstream of the independent non-base layer rewriting process of clause F.10.2 with the input variables `assignedBaseLayerId` equal to `LayerSetLayerIdList[OlsIdxToLsIdx[olsIdx][0]]` and `tIdTarget` equal to 6:
 - `num_add_layer_sets` is greater than 0.
 - `OlsIdxToLsIdx[olsIdx]` is in the range of `FirstAddLayerSetIdx` to `LastAddLayerSetIdx`, inclusive.
 - `NumLayersInLsList[OlsIdxToLsIdx[olsIdx]]` is equal to 1.
 - The `profile_tier_level()` syntax structure `VpsProfileTierLevel[profile_tier_level_idx[olsIdx][0]]` indicates a profile specified in Annex A.
 - The value of `general_inbld_flag` in the `profile_tier_level()` syntax structure `VpsProfileTierLevel[profile_tier_level_idx[olsIdx][0]]` is equal to 1.
- Otherwise, the `profile_tier_level()` syntax structure provides profile, tier and level to which a layer in an OLS conforms and the `profile_tier_level_idx[i][j]` syntax element specifies that the `profile_tier_level()` syntax structure `VpsProfileTierLevel[profile_tier_level_idx[i][j]]` applies to the `j`-th layer of the `i`-th OLS.

NOTE 1 – When `vps_base_layer_internal_flag` is equal to 1 and `vps_max_layers_minus1` is greater than 0, the value of `profile_tier_level_idx[0][0]` is inferred to be equal to 1, such that `VpsProfileTierLevel[1]` applies to the 0-th OLS, which contains only the base layer that is the only output layer.

When the `profile_tier_level()` syntax structure is `VpsProfileTierLevel[k]` for `k` greater than 0 and `profilePresentFlag` is equal to 0, the syntax elements `general_profile_space`, `general_tier_flag`, `general_profile_idc`, `general_profile_compatibility_flag[j]`, `general_progressive_source_flag`, `general_interlaced_source_flag`, `general_non_packed_constraint_flag`, `general_frame_only_constraint_flag`, `general_max_12bit_constraint_flag`, `general_max_10bit_constraint_flag`, `general_max_8bit_constraint_flag`, `general_max_422chroma_constraint_flag`, `general_max_420chroma_constraint_flag`, `general_max_monochrome_constraint_flag`, `general_intra_constraint_flag`, `general_one_picture_only_constraint_flag`, `general_lower_bit_rate_constraint_flag`, `general_max_14bit_constraint_flag`, `general_reserved_zero_33bits`, `general_reserved_zero_34bits`, `general_reserved_zero_7bits`, `general_reserved_zero_35bits`, `general_reserved_zero_43bits`, `general_inbld_flag` and `general_reserved_zero_1bit` are not present in the `profile_tier_level()` syntax structure and each is inferred to be equal to the value of corresponding syntax element of the `profile_tier_level()` syntax structure `VpsProfileTierLevel[k – 1]`.

When the `profile_tier_level()` syntax structure is `VpsProfileTierLevel[k]` for `k` greater than 0 and any of the syntax elements `sub_layer_profile_space[i]`, `sub_layer_tier_flag[i]`, `sub_layer_profile_idc[i]`, `sub_layer_profile_compatibility_flag[i][j]`, `sub_layer_progressive_source_flag[i]`, `sub_layer_interlaced_source_flag[i]`, `sub_layer_non_packed_constraint_flag[i]`, `sub_layer_frame_only_constraint_flag[i]`, `sub_layer_max_12bit_constraint_flag[i]`, `sub_layer_max_10bit_constraint_flag[i]`, `sub_layer_max_8bit_constraint_flag[i]`, `sub_layer_max_422chroma_constraint_flag[i]`, `sub_layer_max_420chroma_constraint_flag[i]`, `sub_layer_max_monochrome_constraint_flag[i]`, `sub_layer_intra_constraint_flag[i]`, `sub_layer_one_picture_only_constraint_flag[i]`, `sub_layer_lower_bit_rate_constraint_flag[i]`, `sub_layer_max_14bit_constraint_flag[i]`, `sub_layer_reserved_zero_33bits[i]`, `sub_layer_reserved_zero_34bits[i]`, `sub_layer_reserved_zero_7bits[i]`, `sub_layer_reserved_zero_35bits[i]`, `sub_layer_reserved_zero_43bits[i]`, `sub_layer_inbld_flag[i]`, `sub_layer_reserved_zero_1bit[i]` and `sub_layer_level_idc[i]` is not present for any value of `i` in the range of 0 to `maxNumSubLayersMinus1 – 1`, inclusive, in the `profile_tier_level()` syntax structure, the value of the syntax element is inferred to be equal to the value of the corresponding syntax element of the `profile_tier_level()` syntax structure `VpsProfileTierLevel[k – 1]`.

A sequence of pictures picSeq is derived as follows:

- If the profile_tier_level() syntax structure is included in an SPS, picSeq consists of the pictures in the CLVS of the layer for which the SPS is the active SPS.
- Otherwise, if the profile_tier_level() syntax structure is VpsProfileTierLevel[0], picSeq consists of the pictures with nuh_layer_id equal to 0 in the CVS.
- Otherwise, if vps_max_layers_minus1 is greater than 0, vps_base_layer_internal_flag is equal to 1 and the profile_tier_level() syntax structure is VpsProfileTierLevel[1], picSeq consists of the pictures with nuh_layer_id equal to 0 in the CVS.
- Otherwise (the profile_tier_level() syntax structure is VpsProfileTierLevel[offsetVal + profile_tier_level_idx[i][j]] for any values of i in the range of 0 to NumOutputLayerSets – 1, inclusive, and j in the range of 0 to NumLayersInIdList[OlsIdxToLsIdx[i]] – 1, inclusive, such that NecessaryLayerFlag[i][j] is equal to 1), picSeq consists of the pictures with nuh_layer_id equal to LayerSetLayerIdList[OlsIdxToLsIdx[i]][j] in the CVS.

general_progressive_source_flag and **general_interlaced_source_flag** are interpreted as follows:

- If general_progressive_source_flag is equal to 1 and general_interlaced_source_flag is equal to 0, the source scan type of the pictures in the picSeq should be interpreted as progressive only.
- Otherwise, if general_progressive_source_flag is equal to 0 and general_interlaced_source_flag is equal to 1, the source scan type of the pictures in the picSeq should be interpreted as interlaced only.
- Otherwise, if general_progressive_source_flag is equal to 0 and general_interlaced_source_flag is equal to 0, the source scan type of the pictures in the picSeq should be interpreted as unknown or unspecified.
- Otherwise, general_progressive_source_flag is equal to 1 and general_interlaced_source_flag is equal to 1, the source scan type of each picture in the picSeq is indicated at the picture level using the syntax element source_scan_type in a picture timing SEI message or the syntax element ffinfo_source_scan_type in a frame-field information SEI message.

NOTE 2 – Decoders may ignore the values of general_progressive_source_flag and general_interlaced_source_flag for purposes other than determining the value to be inferred for frame_field_info_present_flag when vui_parameters_present_flag is equal to 0, as there are no other decoding process requirements associated with the values of these flags. Moreover, the actual source scan type of the pictures is outside the scope of this Specification and the method by which the encoder selects the values of general_progressive_source_flag and general_interlaced_source_flag is unspecified.

general_non_packed_constraint_flag equal to 1 specifies that there are neither frame packing arrangement SEI messages nor segmented rectangular frame packing arrangement SEI messages present for the pictures of picSeq. general_non_packed_constraint_flag equal to 0 indicates that there may or may not be one or more frame packing arrangement SEI messages or segmented rectangular frame packing arrangement SEI messages present for the pictures of picSeq.

NOTE 3 – Decoders may ignore the value of general_non_packed_constraint_flag, as there are no decoding process requirements associated with the presence or interpretation of frame packing arrangement SEI messages or segmented rectangular frame packing arrangement SEI messages.

general_frame_only_constraint_flag equal to 1 specifies that field_seq_flag in the active SPSs for the pictures of picSeq is equal to 0. general_frame_only_constraint_flag equal to 0 indicates that field_seq_flag in the active SPSs for the pictures of picSeq may or may not be equal to 0.

NOTE 4 – Decoders may ignore the value of general_frame_only_constraint_flag, as there are no decoding process requirements associated with the value of field_seq_flag.

NOTE 5 – When general_progressive_source_flag is equal to 1, general_frame_only_constraint_flag may or may not be equal to 1.

It is a requirement of bitstream conformance that when olsIdx is such that alt_output_layer_flag[olsIdx] is equal to 1, general_progressive_source_flag, general_interlaced_source_flag, general_non_packed_constraint_flag and general_frame_only_constraint_flag in VpsProfileTierLevel[offsetVal + profile_tier_level_idx[olsIdx][j]] shall be equal to general_progressive_source_flag, general_interlaced_source_flag, general_non_packed_constraint_flag and general_frame_only_constraint_flag, respectively, in VpsProfileTierLevel[offsetVal + profile_tier_level_idx[olsIdx][k]] for any values of j and k in the range of 0 to NumLayersInIdList[OlsIdxToLsIdx[olsIdx]] – 1, inclusive, such that NecessaryLayerFlag[olsIdx][j] is equal to 1 and NecessaryLayerFlag[olsIdx][k] is equal to 1.

F.7.4.5 Scaling list data semantics

The specifications in clause 7.4.5 apply.

F.7.4.6 Supplemental enhancement information message semantics

The specifications in clause 7.4.6 apply.

F.7.4.7 Slice segment header semantics

F.7.4.7.1 General slice segment header semantics

The specifications in clause 7.4.7.1 apply with the replacement of references to Annex C with references to clause F.13 and with the following additions:

When present, the value of the slice segment header syntax elements `discardable_flag`, `cross_layer_bla_flag`, `inter_layer_pred_enabled_flag`, `num_inter_layer_ref_pics_minus1`, `poc_reset_idc`, `poc_reset_period_id`, `full_poc_reset_flag`, `poc_lsb_val`, `poc_msb_cycle_val_present_flag` and `poc_msb_cycle_val` shall be the same in all slice segment headers of a coded picture. When present, the value of the slice segment header syntax elements `inter_layer_pred_layer_idc[i]` shall be the same in all slice segment headers of a coded picture for each possible value of `i`.

When `nal_unit_type` has a value in the range of `BLA_W_LP` to `RSV_IRAP_VCL23`, inclusive, i.e., the picture is an IRAP picture, `NumDirectRefLayers[nuh_layer_id]` is equal to 0, and `pps_curr_pic_ref_enabled_flag` is equal to 0, `slice_type` shall be equal to 2.

When `sps_max_dec_pic_buffering_minus1[TemporalId]` is equal to 0, `NumDirectRefLayers[nuh_layer_id]` is equal to 0, and `pps_curr_pic_ref_enabled_flag` is equal to 0, `slice_type` shall be equal to 2.

discardable_flag equal to 1 specifies that the coded picture is not used as a reference picture for inter prediction and is not used as a source picture for inter-layer prediction in the decoding process of subsequent pictures in decoding order. `discardable_flag` equal to 0 specifies that the coded picture may be used as a reference picture for inter prediction and may be used as a source picture for inter-layer prediction in the decoding process of subsequent pictures in decoding order. When `nal_unit_type` is equal to `TRAIL_R`, `TSA_R`, `STSA_R`, `RASL_R` or `RADL_R`, the value of `discardable_flag` shall be equal to 0. When not present, the value of `discardable_flag` is inferred to be equal to 0.

NOTE 1 – When a coded picture has `discardable_flag` equal to 1 in its slice headers, the picture may be ignored by decoders without affecting the decoding result of any other picture, in the same layer or a different layer.

cross_layer_bla_flag equal to 1 affects the derivation of `NoClnsOutputFlag` and `LayerResetFlag` as specified in clause F.8.1.3. `cross_layer_bla_flag` shall be equal to 0 for pictures with `nal_unit_type` not equal to `IDR_W_RADL` or `IDR_N_LP` or with `nuh_layer_id` `nuhLayerId` not equal to any value for which `NumDirectRefLayers[nuhLayerId]` is equal to 0. When not present, the value of `cross_layer_bla_flag` is inferred to be equal to 0.

When `vps_extension_flag` is equal to 1, the sum of `NumNegativePics[CurrRpsIdx]`, `NumPositivePics[CurrRpsIdx]`, `num_long_term_sps` and `num_long_term_pics` shall be less than or equal to `MaxDpbSize – 1`, where `MaxDpbSize` is as specified in clause G.11.2 or H.11.2.

NOTE 2 – The way that `MaxDpbSize` is specified in clause G.11.2 is the same as in clause H.11.2.

inter_layer_pred_enabled_flag equal to 1 specifies that inter-layer prediction may be used in decoding of the current picture. `inter_layer_pred_enabled_flag` equal to 0 specifies that inter-layer prediction is not used in decoding of the current picture.

num_inter_layer_ref_pics_minus1 plus 1 specifies the number of pictures that may be used in decoding of the current picture for inter-layer prediction. The length of the `num_inter_layer_ref_pics_minus1` syntax element is $\text{Ceil}(\text{Log2}(\text{NumDirectRefLayers}[\text{nuh_layer_id}]))$ bits. The value of `num_inter_layer_ref_pics_minus1` shall be in the range of 0 to `NumDirectRefLayers[nuh_layer_id] – 1`, inclusive.

The variables `numRefLayerPics` and `refLayerPicIdc[j]` are derived as follows:

```
for( i = 0, j = 0; i < NumDirectRefLayers[ nuh_layer_id ]; i++ ) {  
    refLayerIdx = LayerIdxInVps[ IdDirectRefLayer[ nuh_layer_id ][ i ] ]  
    if( sub_layers_vps_max_minus1[ refLayerIdx ] >= TemporalId && ( TemporalId == 0 || (F-52)  
        max_tid_il_ref_pics_plus1[ refLayerIdx ][ LayerIdxInVps[ nuh_layer_id ] ] >  
        TemporalId ) )  
        refLayerPicIdc[ j++ ] = i  
}  
numRefLayerPics = j
```

The variable `NumActiveRefLayerPics` is derived as follows:

```
if( nuh_layer_id == 0 || numRefLayerPics == 0 )  
    NumActiveRefLayerPics = 0  
else if( default_ref_layers_active_flag )  
    NumActiveRefLayerPics = numRefLayerPics  
else if( !inter_layer_pred_enabled_flag )  
    NumActiveRefLayerPics = 0
```

(F-53)

```

else if( max_one_active_ref_layer_flag || NumDirectRefLayers[ nuh_layer_id ] == 1 )
    NumActiveRefLayerPics = 1
else
    NumActiveRefLayerPics = num_inter_layer_ref_pics_minus1 + 1

```

All slices of a coded picture shall have the same value of NumActiveRefLayerPics.

inter_layer_pred_layer_idc[i] specifies the variable, RefPicLayerId[i], representing the nuh_layer_id of the i-th picture that may be used by the current picture for inter-layer prediction. The length of the inter_layer_pred_layer_idc[i] syntax element is $\text{Ceil}(\text{Log}_2(\text{NumDirectRefLayers}[\text{nuh_layer_id}]))$ bits. The value of inter_layer_pred_layer_idc[i] shall be in the range of 0 to NumDirectRefLayers[nuh_layer_id] - 1, inclusive. When i is greater than 0, inter_layer_pred_layer_idc[i] shall be greater than inter_layer_pred_layer_idc[i - 1]. When not present, the value of inter_layer_pred_layer_idc[i] is inferred to be equal to refLayerPicIdc[i].

The variables RefPicLayerId[i] for all values of i in the range of 0 to NumActiveRefLayerPics - 1, inclusive, are derived as follows:

```

for( i = 0; i < NumActiveRefLayerPics; i++ )                                     (F-54)
    RefPicLayerId[ i ] = IdDirectRefLayer[ nuh_layer_id ][ inter_layer_pred_layer_idc[ i ] ]

```

It is a requirement of bitstream conformance that for each value of i in the range of 0 to NumActiveRefLayerPics - 1, inclusive, either of the following two conditions shall be true:

- The value of max_tid_il_ref_pics_plus1[LayerIdxInVps[RefPicLayerId[i]]][LayerIdxInVps[nuh_layer_id]] is greater than TemporalId.
- The values of max_tid_il_ref_pics_plus1[LayerIdxInVps[RefPicLayerId[i]]][LayerIdxInVps[nuh_layer_id]] and TemporalId are both equal to 0 and the picture in the current access unit with nuh_layer_id equal to RefPicLayerId[i] is an IRAP picture.

poc_reset_idc equal to 0 specifies that neither the most significant bits nor the least significant bits of the picture order count value for the current picture are reset. poc_reset_idc equal to 1 specifies that only the most significant bits of the picture order count value for the current picture may be reset. poc_reset_idc equal to 2 specifies that both the most significant bits and the least significant bits of the picture order count value for the current picture may be reset. poc_reset_idc equal to 3 specifies that either only the most significant bits or both the most significant bits and the least significant bits of the picture order count value for the current picture may be reset and additional picture order count information is signalled. When not present, the value of poc_reset_idc is inferred to be equal to 0.

It is a requirement of bitstream conformance that the following constraints apply:

- The value of poc_reset_idc shall not be equal to 1 or 2 for a RASL, RADL, or SLNR picture or a picture that has TemporalId greater than 0, or a picture that has discardable_flag equal to 1.
- The value of poc_reset_idc of all coded pictures that are present in the bitstream in an access unit shall be the same.
- When the picture in an access unit with nuh_layer_id equal to 0 is an IRAP picture and vps_base_layer_internal_flag is equal to 1 and there is at least one other picture in the same access unit that is not an IRAP picture, the value of poc_reset_idc shall be equal to 1 or 2 for all pictures in the access unit.
- When there is at least one picture that has nuh_layer_id greater than 0 and that is an IDR picture with a particular value of nal_unit_type in an access unit and there is at least one other coded picture that is present in the bitstream in the same access unit with a different value of nal_unit_type, the value of poc_reset_idc shall be equal to 1 or 2 for all pictures in the access unit.
- The value of poc_reset_idc of a CRA or BLA picture shall be less than 3.
- When the picture with nuh_layer_id equal to 0 in an access unit is an IDR picture and vps_base_layer_internal_flag is equal to 1 and there is at least one non-IDR picture in the same access unit, the value of poc_reset_idc shall be equal to 2 for all pictures in the access unit.
- When the picture with nuh_layer_id equal to 0 in an access unit is not an IDR picture and vps_base_layer_internal_flag is equal to 1, the value of poc_reset_idc shall not be equal to 2 for any picture in the access unit.
- When poc_lsb_not_present_flag[LayerIdxInVps[nuh_layer_id]] is equal to 1 and slice_pic_order_cnt_lsb is greater than 0, the value of poc_reset_idc shall not be equal to 2.

The value of poc_reset_idc of an access unit is the value of poc_reset_idc of the pictures in the access unit.

NOTE 3 – Encoders should be cautious in setting the value of poc_reset_idc of pictures when there is a picture of a layer not present in an access unit or there is a picture with discardable_flag equal to 1 present in an access unit, to ensure that the derived picture

order count values of pictures within an access unit are cross-layer aligned. Basically, such cases should be treated similarly as access units with non-cross-layer-aligned IRAP pictures in terms of whether POC resetting is needed.

NOTE 4 – As specified in clause F.8.3.1, the most significant bits of the PicOrderCntVal of an IDR picture with poc_reset_idc equal to 0 are set equal to 0. As specified for the decoder conformance of output order DPB in clause F.13.5.2.2, an IDR picture with nuh_layer_id equal to SmallestLayerId does not cause the output of earlier access units, in decoding order, unless the IDR picture is a POC resetting picture, activates a new VPS, or causes NoClasOutputFlag to be derived to be equal to 1. Encoders should be cautious when using poc_reset_idc equal to 0 with IDR pictures to maintain the desired picture output order and to obey the constraints on the consistent relation of output times to picture order counts as well as the constraints on the output order of two pictures in different CVSs.

poc_reset_period_id identifies a POC resetting period. When not present, the value of poc_reset_period_id is inferred as follows:

- If there is no picture that is in the same layer as the current picture, precedes the current picture in decoding order, and has poc_reset_period_id present in the slice segment header, the value of poc_reset_period_id is inferred to be equal to 0.
- Otherwise, the value of poc_reset_period_id is inferred to be equal to poc_reset_period_id of the last of such pictures, in decoding order, that are in the same layer as the current picture, precede the current picture in decoding order, and has poc_reset_period_id present in the slice segment header.

NOTE 5 – It is not prohibited for multiple pictures in a layer to have the same value of poc_reset_period_id and to have poc_reset_idc equal to 1 or 2 unless such pictures occur in two consecutive access units in decoding order. To minimize the likelihood of such two pictures appearing in the bitstream due to picture losses, bitstream extraction, seeking, or splicing operations, encoders should set the value of poc_reset_period_id to be a random value for each POC resetting period (subject to the constraints specified above).

It is a requirement of bitstream conformance that the following constraints apply:

- There shall be no two pictures consecutive in decoding order in the same layer that have the same value of poc_reset_period_id and poc_reset_idc equal to 1 or 2.
- One POC resetting period shall not include more than one access unit with poc_reset_idc equal to 1 or 2.
- An access unit with poc_reset_idc equal to 1 or 2 shall be the first access unit in a POC resetting period.
- A picture that follows, in decoding order, the first POC resetting picture among all layers of a POC resetting period in decoding order shall not precede, in output order, another picture in any layer that precedes the first POC resetting picture in decoding order.
- The value of poc_reset_period_id shall be the same for all pictures in an access unit.

full_poc_reset_flag equal to 1 specifies that both the most significant bits and the least significant bits of the picture order count value for the current picture are reset when the previous picture in decoding order in the same layer does not belong to the same POC resetting period. full_poc_reset_flag equal to 0 specifies that only the most significant bits of the picture order count value for the current picture are reset when the previous picture in decoding order in the same layer does not belong to the same POC resetting period.

It is a requirement of bitstream conformance that when the value of poc_reset_idc of pictures in the first access unit in the same POC resetting period is equal to 1 or 2, the value of full_poc_reset_flag, when present, shall be equal to poc_reset_idc – 1.

poc_lsb_val specifies a value that may be used to derive the picture order count of the current picture. The length of the poc_lsb_val syntax element is log2_max_pic_order_cnt_lsb_minus4 + 4 bits.

When poc_lsb_not_present_flag[LayerIdxInVps[nuh_layer_id]] is equal to 1 and full_poc_reset_flag is equal to 1, the value of poc_lsb_val shall be equal to 0.

It is a requirement of bitstream conformance that, when poc_reset_idc is equal to 3, and the previous picture picA in decoding order that is in the same layer as the current picture, that has poc_reset_idc equal to 1 or 2, and that belongs to the same POC resetting period is present in the bitstream, picA shall be the same picture as the previous picture in decoding order that is in the same layer as the current picture, that is not a RASL, RADL, or SLNR picture, and that has TemporalId equal to 0 and discardable_flag equal to 0, and the value of poc_lsb_val of the current picture shall be equal to the value of slice_pic_order_cnt_lsb of picA.

The variable PocMsbValRequiredFlag is derived as follows:

$$\text{PocMsbValRequiredFlag} = \text{CraOrBlaPicFlag} \ \&\& \ (!\text{vps_poc_lsb_aligned_flag} \ || \ (\text{vps_poc_lsb_aligned_flag} \ \&\& \ \text{NumDirectRefLayers[nuh_layer_id]} == 0)) \quad (\text{F-55})$$

poc_msb_cycle_val_present_flag equal to 1 specifies that **poc_msb_cycle_val** is present. **poc_msb_cycle_val_present_flag** equal to 0 specifies that **poc_msb_cycle_val** is not present. When not present, the value of **poc_msb_cycle_val_present_flag** is inferred as follows:

- If **slice_segment_header_extension_length** is equal to 0, the value of **poc_msb_cycle_val_present_flag** is inferred to be equal to 0.
- Otherwise, if **PocMsbValRequiredFlag** is equal to 1, the value of **poc_msb_cycle_val_present_flag** is inferred to be equal to 1.
- Otherwise, the value of **poc_msb_cycle_val_present_flag** is inferred to be equal to 0.

NOTE 6 – When the current picture is an IDR picture with **nuh_layer_id** equal to 0 and is a POC resetting picture, **vps_poc_lsb_aligned_flag** is equal to 1 and **NumPredictedLayers[0]** is greater than 0, **poc_msb_cycle_val_present_flag** should be equal to 1.

poc_msb_cycle_val specifies the value that may be used to derive the picture order count value of the current picture or used to derive the value used to decrement the picture order count values of previously decoded pictures in the same layer as the current picture. When **vps_poc_lsb_aligned_flag** is equal to 1, **poc_msb_cycle_val** may also specify the value that is used to derive the value used to decrement the picture order count values of previously decoded pictures of the predicted layers of the current layer. The value of **poc_msb_cycle_val** shall be in the range of 0 to $2^{32 - \log_2 \text{max_pic_order_cnt_lsb_minus4} - 4}$, inclusive.

NOTE 7 – For a picture **picA** in layer **layerA**, let **msbAnchorPic** of the picture **picA** be the previous POC resetting picture in the layer **layerA** or the previous IDR picture that belongs to the layer **layerA** and has **poc_msb_cycle_val_present_flag** equal to 0, whichever is closer, in decoding order, to the picture **picA**. The value of **poc_msb_cycle_val** is set as follows:

- If **vps_poc_lsb_aligned_flag** is equal to 0, the following applies:
 - If either of the following conditions is true, the value of **poc_msb_cycle_val** can be any value in the allowed range:
 - **msbAnchorPic** of the current picture is not present.
 - the current picture is the first picture in the current layer that belongs to or follows an access unit that contains an IRAP picture with **nuh_layer_id** equal to **SmallestLayerId** and **NoClasOutputFlag** equal to 1.
 - Otherwise, if the current picture is a POC resetting picture, the value of **poc_msb_cycle_val** is equal to the difference between the values of the most significant bits of the picture order counts of the current picture, as if there was no POC reset operation for the current picture, and **msbAnchorPic** of the current picture.
 - Otherwise (the current picture is not a POC resetting picture), the value of **poc_msb_cycle_val** is equal to the difference between the values of the most significant bits of the picture order count values of the current picture and **msbAnchorPic** of the current picture.
- Otherwise (**vps_poc_lsb_aligned_flag** is equal to 1), the following applies:
 - If the current picture is an IDR picture with **nuh_layer_id** equal to 0 and is a POC resetting picture, encoders should set the value of **poc_msb_cycle_val** as follows:
 - If picture **picB** other than the current picture is present in the current access unit, the difference between the most significant bits of the picture order counts of **picB** and **msbAnchorPic** of **picB**.
 - Otherwise (no picture **picB** other than the current picture is present in the current access unit), the difference between the most significant bits of the picture order counts of **picB** as if it would be present in the current access unit and **msbAnchorPic** of such a **picB**.
 - Otherwise, if the current picture is the first picture in the POC resetting period and has **nuh_layer_id** equal to **SmallestLayerId**, the value of **poc_msb_cycle_val** is equal to the difference between the values of the most significant bits of the picture order counts of the current picture, as if there was no POC reset operation for the current picture, and **msbAnchorPic** of the current picture.
 - Otherwise when the current picture is not a POC resetting picture, the value of **poc_msb_cycle_val** is equal to the difference between the values of the most significant bits of the picture order count values of the current picture and **msbAnchorPic** of the current picture.

slice_segment_header_extension_data_bit may have any value. Decoders shall ignore the value of **slice_segment_header_extension_data_bit**. Its value does not affect the decoding process specified in this version of this Specification.

7.7.4.7.2 Reference picture list modification semantics

The specifications in clause 7.4.7.2 apply with following modifications:

- Equation 7-57 specifying the derivation of **NumPicTotalCurr** is replaced by:

```

NumPicTotalCurr = 0
if( nal_unit_type != IDR_W_RADL && nal_unit_type != IDR_N_LP ) {
    for( i = 0; i < NumNegativePics[ CurrRpsIdx ]; i++ )
        if( UsedByCurrPicS0[ CurrRpsIdx ][ i ] )
            NumPicTotalCurr++
    for( i = 0; i < NumPositivePics[ CurrRpsIdx ]; i++ )
        if( UsedByCurrPicS1[ CurrRpsIdx ][ i ] )
            NumPicTotalCurr++
    for( i = 0; i < num_long_term_sps + num_long_term_pics; i++ )
        if( UsedByCurrPicLt[ i ] )
            NumPicTotalCurr++
}
if( pps_curr_pic_ref_enabled_flag )
    NumPicTotalCurr++
NumPicTotalCurr += NumActiveRefLayerPics

```

(F-56)

F.7.4.7.3 Weighted prediction parameters semantics

The specifications in clause 7.4.7.3 apply.

F.7.4.8 Short-term reference picture set semantics

The specifications in clause 7.4.8 apply, with the following additions:

When `vps_extension_flag` is equal to 1, the value of `num_negative_pics` shall be in the range of 0 to `MaxDpbSize - 1`, inclusive, where `MaxDpbSize` is as specified in clause G.11.2 or H.11.2.

When `vps_extension_flag` is equal to 1, the value of `num_positive_pics` shall be in the range of 0 to `MaxDpbSize - 1 - num_negative_pics`, inclusive, where `MaxDpbSize` is as specified in clause G.11.2 or H.11.2.

F.7.4.9 Slice segment data semantics

F.7.4.9.1 General slice segment data semantics

The specifications in clause 7.4.9.1 apply.

F.7.4.9.2 Coding tree unit semantics

The specifications in clause 7.4.9.2 apply.

F.7.4.9.3 Sample adaptive offset semantics

The specifications in clause 7.4.9.3 apply.

F.7.4.9.4 Coding quadtree semantics

The specifications in clause 7.4.9.4 apply.

F.7.4.9.5 Coding unit semantics

The specifications in clause 7.4.9.5 apply.

F.7.4.9.6 Prediction unit semantics

The specifications in clause 7.4.9.6 apply.

F.7.4.9.7 PCM sample semantics

The specifications in clause 7.4.9.7 apply.

F.7.4.9.8 Transform tree semantics

The specifications in clause 7.4.9.8 apply.

F.7.4.9.9 Motion vector difference semantics

The specifications in clause 7.4.9.9 apply.

F.7.4.9.10 Transform unit semantics

The specifications in clause 7.4.9.10 apply.

F.7.4.9.11 Residual coding semantics

The specifications in clause 7.4.9.11 apply.

F.7.4.9.12 Cross-component prediction syntax

The specifications in clause 7.4.9.12 apply.

F.7.4.9.13 Palette mode semantics

The specifications in clause 7.4.9.13 apply.

F.7.4.9.14 Delta QP semantics

The specifications in clause 7.4.9.14 apply.

F.7.4.9.15 Chroma QP offset semantics

The specifications in clause 7.4.9.15 apply.

F.8 Decoding process

F.8.1 General decoding process

F.8.1.1 General

Input to this process is a bitstream. Output of this process is a list of decoded pictures.

The decoding process is specified such that all decoders capable of decoding an OLS where each of the output layers and the reference layers of the output layers is indicated to conform to a specified profile, tier and level will produce numerically identical cropped decoded output pictures when invoking the decoding process associated with those profiles for the OLS. Any decoding process that produces identical cropped decoded output pictures to those produced by the process described herein (with the correct output order or output timing, as specified) conforms to the decoding process requirements of this Specification.

The following applies at the beginning of decoding a CVSG, after activating the VPS RBSP that is active for the entire CVSG and before decoding any VCL NAL units of the CVSG:

- If `vps_extension()` is not present in the active VPS or a decoding process specified in this annex is not in use, clause 8.1.2 is invoked with the CVSG as input.
- Otherwise (`vps_extension()` is present in the active VPS and a decoding process specified in this annex is in use), clause F.8.1.2 is invoked with the CVSG as input.

F.8.1.2 CVSG decoding process

Input to this process is a CVSG. Output of this process is a list of decoded pictures.

The variable `TargetOlsIdx`, which specifies the index to the list of the OLSs specified by the VPS, of the target OLS, is specified as follows:

- If some external means, not specified in this Specification, is available to set `TargetOlsIdx`, `TargetOlsIdx` is set by the external means.
- Otherwise, if the decoding process is invoked in a bitstream conformance test as specified in clause F.13.1, `TargetOlsIdx` is set as specified in clause F.13.1.
- Otherwise, `TargetOlsIdx` is set equal to 0.

The variable `TargetDecLayerSetIdx`, the layer identifier list `TargetOptLayerIdList`, which specifies the list of `nuh_layer_id` values, in increasing order of `nuh_layer_id` values, of the pictures to be output and the layer identifier list `TargetDecLayerIdList`, which specifies the list of `nuh_layer_id` values, in increasing order of `nuh_layer_id` values, of the NAL units to be decoded, are specified as follows:

```
TargetDecLayerSetIdx = OlsIdxToLsIdx[ TargetOlsIdx ]
lsIdx = TargetDecLayerSetIdx
for( i = 0, j = 0, k = 0; i < NumLayersInIdList[ lsIdx ]; i++ ) {
```

```

    if( NecessaryLayerFlag[ TargetOlsIdx ][ i ] )
        TargetDecLayerIdList[ j++ ] = LayerSetLayerIdList[ lsIdx ][ i ]
    if( OutputLayerFlag[ TargetOlsIdx ][ i ] )
        TargetOptLayerIdList[ k++ ] = LayerSetLayerIdList[ lsIdx ][ i ]
}

```

(F-57)

When TargetOlsIdx is set by external means, it is a requirement for the external means that TargetOlsIdx is constrained as follows:

- When vps_base_layer_available_flag is equal to 0, OlsIdxToLsIdx[TargetOlsIdx] shall be in the range of FirstAddLayerSetIdx to LastAddLayerSetIdx, inclusive.
- When vps_base_layer_internal_flag is equal to 0, TargetOlsIdx shall be greater than 0.

The variable HighestTid, which identifies the highest temporal sub-layer to be decoded, is specified as follows:

- If some external means, not specified in this Specification, is available to set HighestTid, HighestTid is set by the external means.
- Otherwise, if the decoding process is invoked in a bitstream conformance test as specified in clause F.13.1 HighestTid is set as specified in clause F.13.1.
- Otherwise, HighestTid is set equal to vps_max_sub_layers_minus1.

The variable SubPicHrdPreferredFlag is either specified by external means, or when not specified by external means, set equal to 0.

The variable SubPicHrdFlag is specified as follows:

- If the decoding process is invoked in a bitstream conformance test as specified in clause F.13.1, SubPicHrdFlag is set as specified in clause F.13.1.
- Otherwise, SubPicHrdFlag is set equal to (SubPicHrdPreferredFlag && sub_pic_hrd_params_present_flag), where sub_pic_hrd_params_present_flag is found in any hrd_parameters() syntax structure that applies to at least one bitstream partition of the output layer set identified by TargetOlsIdx.

A bitstream to be decoded, BitstreamToDecode, is specified as follows:

- If TargetDecLayerSetIdx is less than or equal to vps_num_layer_sets_minus1 and vps_base_layer_internal_flag is equal to 1, the following applies:
 - The sub-bitstream extraction process as specified in clause 10 is applied with the CVSG, HighestTid and TargetDecLayerIdList as inputs, and the output is assigned to a bitstream referred to as BitstreamToDecode.
 - The variable SmallestLayerId is set equal to 0.
- Otherwise, if TargetDecLayerSetIdx is less than or equal to vps_num_layer_sets_minus1 and vps_base_layer_internal_flag is equal to 0, the following applies:
 - The sub-bitstream extraction process as specified in clause F.10.1 is applied with the CVSG, HighestTid and TargetDecLayerIdList as inputs, and the output is assigned to a bitstream referred to as BitstreamToDecode.
 - The variable SmallestLayerId is set equal to 0.
- Otherwise, if TargetDecLayerSetIdx is greater than vps_num_layer_sets_minus1 and NumLayersInIdList[TargetDecLayerSetIdx] is equal to 1, the following applies:
 - The independent non-base layer rewriting process of clause F.10.2 is applied with the CVSG, HighestTid and TargetDecLayerIdList[0] as inputs, and the output is assigned to a bitstream referred to as BitstreamToDecode.
 - The variable SmallestLayerId is set equal to 0.
- Otherwise, the following applies:
 - The sub-bitstream extraction process as specified in clause F.10.3 is applied with the CVSG, HighestTid and TargetDecLayerIdList as inputs, and the output is assigned to a bitstream referred to as BitstreamToDecode.
 - The variable SmallestLayerId is set equal to TargetDecLayerIdList[0].

When vps_base_layer_internal_flag is equal to 0, vps_base_layer_available_flag is equal to 1 and TargetDecLayerSetIdx is in the range of 0 to vps_num_layer_sets_minus1, inclusive, the following applies:

- The size of the sub-DPB for the layer with nuh_layer_id equal to 0 is set equal to 1.

- The values of `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `chroma_format_idc`, `separate_colour_plane_flag`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `conf_win_left_offset`, `conf_win_right_offset`, `conf_win_top_offset` and `conf_win_bottom_offset` for decoded pictures with `nuh_layer_id` equal to 0 are set equal to the values of `pic_width_vps_in_luma_samples`, `pic_height_vps_in_luma_samples`, `chroma_format_vps_idc`, `separate_colour_plane_vps_flag`, `bit_depth_vps_luma_minus8`, `bit_depth_vps_chroma_minus8`, `conf_win_vps_left_offset`, `conf_win_vps_right_offset`, `conf_win_vps_top_offset` and `conf_win_vps_bottom_offset` respectively, of the `vps_rep_format_idx[0]`-th `rep_format()` syntax structure in the active VPS.
- The variable `BaseLayerOutputFlag` is set equal to $(\text{TargetOptLayerIdList}[0] == 0)$.
NOTE – The `BaseLayerOutputFlag` is to be sent by an external means to the base layer decoder for controlling the output of base layer decoded pictures. `BaseLayerOutputFlag` equal to 1 indicates that the base layer is an output layer. `BaseLayerOutputFlag` equal to 0 indicates that the base layer is not an output layer.
- The variable `LayerInitializedFlag[i]` is set equal to 0 for all values of `i` from 0 to `vps_max_layer_id`, inclusive, and the variable `FirstPicInLayerDecodedFlag[i]` is set equal to 0 for all values of `i` from 0 to `vps_max_layer_id`, inclusive.

If `TargetOlsIdx` is equal to 0, clause 8.1.3 is repeatedly invoked for each coded picture in `BitstreamToDecode` in decoding order and the decoding process for the current picture takes as inputs the syntax elements and upper-case variables from clause 7.

Otherwise (`TargetOlsIdx` is greater than 0), clause F.8.1.3 is repeatedly invoked for each coded picture in `BitstreamToDecode` in decoding order.

F.8.1.3 Common decoding process for a coded picture

The decoding processes specified in the remainder of this clause apply to each coded picture, referred to as the current picture and denoted by the variable `CurrPic`, in `BitstreamToDecode`.

Depending on the value of `chroma_format_idc`, the number of sample arrays of the current picture is as follows:

- If `chroma_format_idc` is equal to 0, the current picture consists of 1 sample array `SL`.
- Otherwise (`chroma_format_idc` is not equal to 0), the current picture consists of 3 sample arrays `SL`, `SCb`, `SCr`.

When interpreting the semantics of each syntax element in each NAL unit, the term "the bitstream" (or part thereof, e.g., a CVS of the bitstream) refers to `BitstreamToDecode` (or part thereof).

When `vps_base_layer_internal_flag` is equal to 0, `vps_base_layer_available_flag` is equal to 1, `TargetDecLayerSetIdx` is in the range of 0 to `vps_num_layer_sets_minus1`, inclusive, `TemporalId` is less than or equal to `sub_layers_vps_max_minus1[0]`, and the current picture is the first coded picture of an access unit, clause F.8.1.8 is invoked prior to decoding the current picture.

When the current picture is an IRAP picture, the variable `HandleCraAsBlaFlag` is derived as specified in the following:

- If some external means not specified in this Specification is available to set the variable `HandleCraAsBlaFlag` to a value for the current picture, the variable `HandleCraAsBlaFlag` is set equal to the value provided by the external means.
- Otherwise, the variable `HandleCraAsBlaFlag` is set equal to 0.

When the current picture is an IRAP picture and has `nuh_layer_id` equal to `SmallestLayerId`, the following applies:

- The variable `NoClrasOutputFlag` is specified as follows:
 - If the current picture is the first picture in the bitstream, `NoClrasOutputFlag` is set equal to 1.
 - Otherwise, if the current picture is included in the first access unit that follows an access unit including an end of sequence NAL unit with `nuh_layer_id` equal to `SmallestLayerId` or 0 in decoding order, `NoClrasOutputFlag` is set equal to 1.
 - Otherwise, if the current picture is a BLA picture or a CRA picture with `HandleCraAsBlaFlag` equal to 1, `NoClrasOutputFlag` is set equal to 1.
 - Otherwise, if the current picture is an IDR picture with `cross_layer_bla_flag` is equal to 1, `NoClrasOutputFlag` is set equal to 1.
 - Otherwise, if some external means, not specified in this Specification, is available to set `NoClrasOutputFlag`, `NoClrasOutputFlag` is set by the external means.
 - Otherwise, `NoClrasOutputFlag` is set equal to 0.

- When NoCllasOutputFlag is equal to 1, the variable LayerInitializedFlag[i] is set equal to 0 for all values of i from 0 to vps_max_layer_id, inclusive, and the variable FirstPicInLayerDecodedFlag[i] is set equal to 0 for all values of i from 0 to vps_max_layer_id, inclusive.

The variables LayerResetFlag and dolLayerId are derived as follows:

- If the current picture is an IRAP picture and has nuh_layer_id nuhLayerId greater than SmallestLayerId, the following applies:
 - If the current picture is the first picture, in decoding order, that follows an end of sequence NAL unit with nuh_layer_id equal to nuhLayerId, LayerResetFlag is set equal to 1 and dolLayerId is set equal to the nuh_layer_id value of the current NAL unit.
 - Otherwise, if the current picture is a CRA picture with HandleCraAsBlaFlag equal to 1, an IDR picture with cross_layer_bla_flag is equal to 1 or a BLA picture, LayerResetFlag is set equal to 1 and dolLayerId is set equal to the nuh_layer_id value of the current NAL unit.
 - Otherwise, LayerResetFlag is set equal to 0.

NOTE 1 – An end of sequence NAL unit, a CRA picture with HandleCraAsBlaFlag equal to 1, an IDR picture with cross_layer_bla_flag equal to 1, or a BLA picture, each with nuh_layer_id nuhLayerId greater than SmallestLayerId, may be present to indicate a discontinuity of the layer with nuh_layer_id equal to nuhLayerId and its predicted layers.

- When LayerResetFlag is equal to 1, the following applies:
 - The values of LayerInitializedFlag and FirstPicInLayerDecodedFlag are updated as follows:

```

for( i = 0; i < NumPredictedLayers[ dolLayerId ]; i++ ) {
    iLayerId = IdPredictedLayer[ dolLayerId ][ i ]
    LayerInitializedFlag[ iLayerId ] = 0
    FirstPicInLayerDecodedFlag[ iLayerId ] = 0
}

```

(F-58)

- Each picture that is in the DPB and has nuh_layer_id equal to dolLayerId is marked as "unused for reference".
- When NumPredictedLayers[dolLayerId] is greater than 0, each picture that is in the DPB and has nuh_layer_id equal to any value of IdPredictedLayer[dolLayerId][i] for the values of i in the range of 0 to NumPredictedLayers[dolLayerId] – 1, inclusive, is marked as "unused for reference".
- Otherwise, LayerResetFlag is set equal to 0.

When the current picture is an IRAP picture, the following applies:

- If the current picture with a particular value of nuh_layer_id is an IDR picture, a BLA picture, the first picture with that particular value of nuh_layer_id in the bitstream in decoding order or the first picture with that particular value of nuh_layer_id that follows an end of sequence NAL unit with that particular value of nuh_layer_id in decoding order, the variable NoRaslOutputFlag is set equal to 1.
- Otherwise, if LayerInitializedFlag[nuh_layer_id] is equal to 0 and LayerInitializedFlag[refLayerId] is equal to 1 for all values of refLayerId equal to IdDirectRefLayer[nuh_layer_id][j], where j is in the range of 0 to NumDirectRefLayers[nuh_layer_id] – 1, inclusive, the variable NoRaslOutputFlag is set equal to 1.
- Otherwise, the variable NoRaslOutputFlag is set equal to HandleCraAsBlaFlag.

When the current picture is an IRAP picture with NoRaslOutputFlag equal to 1 and one of the following conditions is true, LayerInitializedFlag[nuh_layer_id] is set equal to 1:

- nuh_layer_id is equal to 0.
- LayerInitializedFlag[nuh_layer_id] is equal to 0 and NumDirectRefLayers[nuh_layer_id] is equal to 0.
- LayerInitializedFlag[nuh_layer_id] is equal to 0 and LayerInitializedFlag[refLayerId] is equal to 1 for all values of refLayerId equal to IdDirectRefLayer[nuh_layer_id][j], where j is in the range of 0 to NumDirectRefLayers[nuh_layer_id] – 1, inclusive.

Depending on the value of separate_colour_plane_flag, the decoding process is structured as follows:

- If separate_colour_plane_flag is equal to 0, the following decoding process is invoked a single time with the current picture being the output.
- Otherwise (separate_colour_plane_flag is equal to 1), the following decoding process is invoked three times. Inputs to the decoding process are all NAL units of the coded picture with identical value of colour_plane_id. The decoding

process of NAL units with a particular value of `colour_plane_id` is specified as if only a CVS with monochrome colour format with that particular value of `colour_plane_id` would be present in the bitstream. The output of each of the three decoding processes is assigned to one of the 3 sample arrays of the current picture, with the NAL units with `colour_plane_id` equal to 0, 1 and 2 being assigned to S_L , S_{Cb} and S_{Cr} , respectively.

NOTE 2 – The variable `ChromaArrayType` is derived as equal to 0 when `separate_colour_plane_flag` is equal to 1 and `chroma_format_idc` is equal to 3. In the decoding process, the value of this variable is evaluated resulting in operations identical to that of monochrome pictures (when `chroma_format_idc` is equal to 0).

The following applies for the decoding of the current picture:

- If the current picture has `nuh_layer_id` equal to 0, the following applies:
 - The decoding process for the current picture takes as inputs the syntax elements and upper-case variables from clause F.7.
 - The variables `NumActiveRefLayerPics`, `NumActiveRefLayerPics0` and `NumActiveRefLayerPics1` are set equal to 0.
 - The decoding process for a coded picture with `nuh_layer_id` equal to 0 as specified in clause F.8.1.4 is invoked.
- Otherwise, the following applies:
 - When `vps_base_layer_internal_flag` is equal to 0, `vps_base_layer_available_flag` is equal to 1, `TargetDecLayerSetIdx` is in the range of 0 to `vps_num_layer_sets_minus1`, inclusive, `TemporalId` is less than or equal to `sub_layers_vps_max_minus1[0]`, the current picture is the first coded picture of an access unit and a decoded picture with `nuh_layer_id` equal to 0 is provided by external means for the current access unit, clause F.8.1.9 is invoked after the decoding of the slice segment header of the first slice segment, in decoding order, of the current picture, but prior to decoding any slice segment of the first coded picture of the access unit.
 - For the decoding of the slice segment header of the first slice segment, in decoding order, of the current picture, the decoding process for starting the decoding of a coded picture with `nuh_layer_id` greater than 0 specified in clause F.8.1.5 is invoked.
 - Let `lIdx` be equal to such value for which the `nuh_layer_id` value of the current picture is equal to `LayerSetLayerIdList[OlsIdxToLsIdx[TargetOlsIdx]][lIdx]`.
 - If `general_profile_idc` in the `profile_tier_level()` syntax structure `VpsProfileTierLevel[profile_tier_level_idx[TargetOlsIdx][lIdx]]` is equal to 6, the decoding process for the current picture takes as inputs the syntax elements and upper-case variables from clause G.7 and the decoding process of clause G.8.1.2 is invoked.
 - Otherwise, if `general_profile_idc` in the `profile_tier_level()` syntax structure `VpsProfileTierLevel[profile_tier_level_idx[TargetOlsIdx][lIdx]]` is equal to 7 or 10, the decoding process for the current picture takes as inputs the syntax elements and upper-case variables from clause H.7 and the decoding process of clause H.8.1.2 is invoked.
 - Otherwise, if `general_profile_idc` in the `profile_tier_level()` syntax structure `VpsProfileTierLevel[profile_tier_level_idx[TargetOlsIdx][lIdx]]` is equal to 8, the decoding process for the current picture takes as inputs the syntax elements and upper-case variables from clause I.7 and the decoding process of clause I.8.1.2 is invoked.
 - Otherwise (the current picture belongs to an independent non-base layer), the decoding process for the current picture takes as inputs the syntax elements and upper-case variables from clause F.7 and the decoding process of clause 8.1.3 is invoked by changing the references to clauses 8.2, 8.3, 8.3.1, 8.3.2, 8.3.3, 8.3.4, 8.4, 8.5, 8.6, and 8.7 with clauses F.8.2, F.8.3, F.8.3.1, F.8.3.2, F.8.3.3, F.8.3.4, F.8.4, F.8.5, F.8.6, and F.8.7, respectively.
 - After all slices of the current picture have been decoded, the decoding process for ending the decoding of a coded picture with `nuh_layer_id` greater than 0 specified in clause F.8.1.6 is invoked.

When the current picture is the last coded picture in an access unit in `BitstreamToDecode`, after the decoding of the current picture, prior to the decoding of the next picture, the following applies:

- `PicOutputFlag` is updated as follows:
 - If `alt_output_layer_flag[TargetOlsIdx]` is equal to 1 and the current access unit either does not contain a picture at the output layer or contains a picture at the output layer that has `PicOutputFlag` equal to 0, the following applies:
 - The list `nonOutputLayerPictures` is set to be the list of the pictures of the access unit with `PicOutputFlag` equal to 1 and with `nuh_layer_id` values among the `nuh_layer_id` values of the reference layers of the output layer.

- When the list nonOutputLayerPictures is not empty, the picture with the highest nuh_layer_id value among the list nonOutputLayerPictures is removed from the list nonOutputLayerPictures.
- PicOutputFlag for each picture that is included in the list nonOutputLayerPictures is set equal to 0.
- Otherwise, PicOutputFlag for pictures that are not included in an output layer is set equal to 0.
- When vps_base_layer_internal_flag is equal to 0, vps_base_layer_available_flag is equal to 1 and TargetDecLayerSetIdx is in the range of 0 to vps_num_layer_sets_minus1, inclusive, the following applies:
 - If BaseLayerOutputFlag is equal to 0, the following applies:
 - If alt_output_layer_flag[TargetOlsIdx] is equal to 1, the base layer is a reference layer of the output layer, the access unit does not contain a picture at the output layer or contains a picture at the output layer that has PicOutputFlag equal to 0, and the access unit does not contain a picture at any other reference layer of the output layer, BaseLayerPicOutputFlag is set equal to 1.
 - Otherwise, BaseLayerPicOutputFlag is set equal to 0.
 - Otherwise, BaseLayerPicOutputFlag is set equal to 1.
- NOTE 3 – The BaseLayerPicOutputFlag for each access unit is to be sent by an external means to the base layer decoder for controlling the output of base layer decoded pictures. BaseLayerPicOutputFlag equal to 1 for an access unit specifies that the base layer picture of the access unit is to be output. BaseLayerPicOutputFlag equal to 0 for an access unit specifies that the base layer picture of the access unit is not to be output.
- The sub-DPB for the layer with nuh_layer_id equal to 0 is set to be empty.
- The variable AuOutputFlag that is associated with the current access unit is derived as follows:
 - If at least one picture in the current access unit has PicOutputFlag equal to 1, AuOutputFlag is set equal to 1.
 - Otherwise, AuOutputFlag is set equal to 0.
- The variable PicLatencyCount that is associated with the current access unit is set equal to 0.
- When AuOutputFlag of the current access unit is equal to 1, for each access unit in the DPB that has at least one picture marked as "needed for output" and follows the current access unit in output order, the associated variable PicLatencyCount is set equal to PicLatencyCount + 1.

F.8.1.4 Decoding process for a coded picture with nuh_layer_id equal to 0

The specifications in clause 8.1.3 apply with the following changes:

- Replace the references to clauses 8.2, 8.3, 8.3.1, 8.3.2, 8.3.3, 8.3.4, 8.4, 8.5, 8.6 and 8.7 with clauses F.8.2, F.8.3, F.8.3.1, F.8.3.2, F.8.3.3, F.8.3.4, F.8.4, F.8.5, F.8.6 and F.8.7, respectively.
- At the end of the clause, add item 5 as follows:
 5. When FirstPicInLayerDecodedFlag[0] is equal to 0, FirstPicInLayerDecodedFlag[0] is set equal to 1.

F.8.1.5 Decoding process for starting the decoding of a coded picture with nuh_layer_id greater than 0

Each picture referred to in this clause is a complete coded picture.

The decoding process operates as follows for the current picture CurrPic:

1. The decoding of NAL units is specified in clause F.8.2.
2. The processes in clause F.8.3 specify the following decoding processes using syntax elements in the slice segment layer and above:
 - Variables and functions relating to picture order count are derived in clause F.8.3.1. This needs to be invoked only for the first slice segment of a picture. It is a requirement of bitstream conformance that PicOrderCntVal of each picture in an access unit shall have the same value during and at the end of decoding of the access unit.

NOTE 1 – When the current picture is or succeeds, in decoding order, an IDR picture with nuh_layer_id equal to 0, PicOrderCntVal of a base layer picture picA preceding, in decoding order, the IDR picture with nuh_layer_id equal to 0 may or may not be equal to PicOrderCntVal of the pictures with nuh_layer_id greater than 0 in the access unit containing picA.
 - The decoding process for RPS in clause F.8.3.2 is invoked, wherein only reference pictures with nuh_layer_id equal to that of CurrPic may be marked as "unused for reference" or "used for long-term

reference" and any picture with a different value of `nuh_layer_id` is not marked. This needs to be invoked only for the first slice segment of a picture.

- A picture storage buffer in the DPB is allocated for storage of the decoded sample values of the current picture after the invocation of the in-loop filter process as specified in clause F.8.7. This version of the current decoded picture is referred to as the current decoded picture after the invocation of the in-loop filter process. When `TwoVersionsOfCurrDecPicFlag` is equal to 0 and `pps_curr_pic_ref_enabled_flag` is equal to 1, this picture storage buffer is marked as "used for long-term reference". When `TwoVersionsOfCurrDecPicFlag` is equal to 1, another picture storage buffer in the DPB is allocated for storage of the decoded sample values of the current picture immediately before the invocation of the in-loop filter process as specified in clause F.8.7, and is marked as "used for long-term reference". This version of the current decoded picture is referred to as the current decoded picture before the invocation of the in-loop filter process. This needs to be invoked only for the first slice segment of a picture.

NOTE 2 – When `TwoVersionsOfCurrDecPicFlag` is equal to 0, there is only one version of the current decoded picture. In this case, if `pps_curr_pic_ref_enabled_flag` is equal to 1, the current decoded picture is marked as "used for long-term reference" during the decoding of the current picture and will be marked as "used for short-term reference" at the end of the decoding of the current picture, otherwise it is not marked at all during the decoding of the current picture and will be marked as "used for short-term reference" at the end of the decoding of the current picture. When `TwoVersionsOfCurrDecPicFlag` is equal to 1, there are two versions of the current decoded picture, one of which is marked as "used for long-term reference" during the decoding of the current picture and will be marked as "unused for reference" at the end of the decoding of the current picture, and the other version is not marked at all during the decoding of the current picture and will be marked as "used for short-term reference" at the end of the decoding of the current picture.

- When `FirstPicInLayerDecodedFlag[nuh_layer_id]` is equal to 0, the decoding process for generating unavailable reference pictures for pictures first in decoding order within a layer specified in clause F.8.1.7 is invoked, which needs to be invoked only for the first slice segment of a picture.
- When `FirstPicInLayerDecodedFlag[nuh_layer_id]` is equal to 1 and the current picture is an IRAP picture with `NoRasOutputFlag` equal to 1, the decoding process for generating unavailable reference pictures specified in clause F.8.3.3 is invoked, which needs to be invoked only for the first slice segment of a picture.

F.8.1.6 Decoding process for ending the decoding of a coded picture with `nuh_layer_id` greater than 0

The marking of decoded pictures is modified as specified in the following:

```
for( i = 0; i < NumActiveRefLayerPics0; i++ )
    RefPicSetInterLayer0[ i ] is marked as "used for short-term reference"
for( i = 0; i < NumActiveRefLayerPics1; i++ )
    RefPicSetInterLayer1[ i ] is marked as "used for short-term reference"
```

(F-59)

`PicOutputFlag` is set as follows:

- If `LayerInitializedFlag[nuh_layer_id]` is equal to 0, `PicOutputFlag` is set equal to 0.
- Otherwise, if the current picture is a RASL picture and `NoRasOutputFlag` of the associated IRAP picture is equal to 1, `PicOutputFlag` is set equal to 0.
- Otherwise, `PicOutputFlag` is set equal to `pic_output_flag`.

The current decoded picture after the invocation of the in-loop filter process as specified in clause 8.7 is marked as "used for short-term reference".

When `FirstPicInLayerDecodedFlag[nuh_layer_id]` is equal to 0, `FirstPicInLayerDecodedFlag[nuh_layer_id]` is set equal to 1.

F.8.1.7 Decoding process for generating unavailable reference pictures for pictures first in decoding order within a layer

This process is invoked for a picture with `nuh_layer_id` equal to `layerId`, when `FirstPicInLayerDecodedFlag[layerId]` is equal to 0.

NOTE – The entire specification of the decoding process for CL-RAS pictures is included only for purposes of specifying constraints on the allowed syntax content of such CL-RAS pictures. During the decoding process, any CL-RAS pictures may be ignored, as these pictures are not specified for output and have no effect on the decoding process of any other pictures that are specified for output. However, in the HRD operations as specified in clause F.13, CL-RAS pictures may need to be taken into consideration in the derivation of CPB arrival and removal times.

When this process is invoked, the following applies:

- For each $\text{RefPicSetStCurrBefore}[i]$, with i in the range of 0 to $\text{NumPocStCurrBefore} - 1$, inclusive, that is equal to "no reference picture", a picture is generated as specified in clause 8.3.3.2 and the following applies:
 - The value of PicOrderCntVal for the generated picture is set equal to $\text{PocStCurrBefore}[i]$.
 - The value of PicOutputFlag for the generated picture is set equal to 0.
 - The generated picture is marked as "used for short-term reference".
 - $\text{RefPicSetStCurrBefore}[i]$ is set to be the generated reference picture.
 - The value of nuh_layer_id for the generated picture is set equal to nuh_layer_id .
- For each $\text{RefPicSetStCurrAfter}[i]$, with i in the range of 0 to $\text{NumPocStCurrAfter} - 1$, inclusive, that is equal to "no reference picture", a picture is generated as specified in clause 8.3.3.2 and the following applies:
 - The value of PicOrderCntVal for the generated picture is set equal to $\text{PocStCurrAfter}[i]$.
 - The value of PicOutputFlag for the generated picture is set equal to 0.
 - The generated picture is marked as "used for short-term reference".
 - $\text{RefPicSetStCurrAfter}[i]$ is set to be the generated reference picture.
 - The value of nuh_layer_id for the generated picture is set equal to nuh_layer_id .
- For each $\text{RefPicSetStFoll}[i]$, with i in the range of 0 to $\text{NumPocStFoll} - 1$, inclusive, that is equal to "no reference picture", a picture is generated as specified in clause 8.3.3.2 and the following applies:
 - The value of PicOrderCntVal for the generated picture is set equal to $\text{PocStFoll}[i]$.
 - The value of PicOutputFlag for the generated picture is set equal to 0.
 - The generated picture is marked as "used for short-term reference".
 - $\text{RefPicSetStFoll}[i]$ is set to be the generated reference picture.
 - The value of nuh_layer_id for the generated picture is set equal to nuh_layer_id .
- For each $\text{RefPicSetLtCurr}[i]$, with i in the range of 0 to $\text{NumPocLtCurr} - 1$, inclusive, that is equal to "no reference picture", a picture is generated as specified in clause 8.3.3.2 and the following applies:
 - The value of PicOrderCntVal for the generated picture is set equal to $\text{PocLtCurr}[i]$.
 - The value of $\text{slice_pic_order_cnt_lsb}$ for the generated picture is inferred to be equal to $(\text{PocLtCurr}[i] \& (\text{MaxPicOrderCntLsb} - 1))$.
 - The value of PicOutputFlag for the generated picture is set equal to 0.
 - The generated picture is marked as "used for long-term reference".
 - $\text{RefPicSetLtCurr}[i]$ is set to be the generated reference picture.
 - The value of nuh_layer_id for the generated picture is set equal to nuh_layer_id .
- For each $\text{RefPicSetLtFoll}[i]$, with i in the range of 0 to $\text{NumPocLtFoll} - 1$, inclusive, that is equal to "no reference picture", a picture is generated as specified in clause 8.3.3.2 and the following applies:
 - The value of PicOrderCntVal for the generated picture is set equal to $\text{PocLtFoll}[i]$.
 - The value of $\text{slice_pic_order_cnt_lsb}$ for the generated picture is inferred to be equal to $(\text{PocLtFoll}[i] \& (\text{MaxPicOrderCntLsb} - 1))$.
 - The value of PicOutputFlag for the generated picture is set equal to 0.
 - The generated picture is marked as "used for long-term reference".
 - $\text{RefPicSetLtFoll}[i]$ is set to be the generated reference picture.
 - The value of nuh_layer_id for the generated picture is set equal to nuh_layer_id .

F.8.1.8 Initialization process for an external base layer picture

A decoded picture with nuh_layer_id equal to 0 may be provided by external means. When not provided, no picture with nuh_layer_id equal to 0 is used for inter-layer prediction for the current access unit. When provided, the following applies:

- The variable `LayerInitializedFlag[0]` is set equal to 1 and the variable `FirstPicInLayerDecodedFlag[0]` is set equal to 1.
- The following information of the picture with `nuh_layer_id` equal to 0 for the access unit is provided by external means:
 - The decoded sample values (1 sample array S_L if `chroma_format_idc` is equal to 0 or 3 sample arrays S_L , S_{Cb} , and S_{Cr} otherwise)
 - The value of the variable `BllrapPicFlag`, and when `BllrapPicFlag` is equal to 1, the value of `nal_unit_type` of the decoded picture
 - `BllrapPicFlag` equal to 1 specifies that the decoded picture is an IRAP picture. `BllrapPicFlag` equal to 0 specifies that the decoded picture is a non-IRAP picture.
 - The provided value of `nal_unit_type` of the decoded picture shall be equal to `IDR_W_RADL`, `CRA_NUT`, or `BLA_W_LP`.
 - `nal_unit_type` equal to `IDR_W_RADL` specifies that the decoded picture is an IDR picture.
 - `nal_unit_type` equal to `CRA_NUT` specifies that the decoded picture is a CRA picture.
 - `nal_unit_type` equal to `BLA_W_LP` specifies that the decoded picture is a BLA picture.
- When `BllrapPicFlag` of the picture with `nuh_layer_id` equal to 0 is equal to 1, the following applies for the decoded picture with `nuh_layer_id` equal to 0 for the access unit:
 - The variable `NoRaslOutputFlag` is specified as follows:
 - If `nal_unit_type` is `IDR_W_RADL` or `BLA_W_LP`, the variable `NoRaslOutputFlag` is set equal to 1.
 - Otherwise, if the current access unit is the first access unit in the bitstream in decoding order, the variable `NoRaslOutputFlag` is set equal to 1.
 - Otherwise, the variable `NoRaslOutputFlag` is set equal to 0.
 - The variable `NoClrasOutputFlag` is specified as follows:
 - If the current access unit is the first access unit in the bitstream, `NoClrasOutputFlag` is set equal to 1.
 - Otherwise, if `nal_unit_type` is equal to `BLA_W_LP`, `NoClrasOutputFlag` is set equal to 1.
 - Otherwise, if some external means, not specified in this Specification, is available to set `NoClrasOutputFlag`, `NoClrasOutputFlag` is set by the external means.
 - Otherwise, `NoClrasOutputFlag` is set equal to 0.
 - When `NoClrasOutputFlag` is equal to 1, the variable `LayerInitializedFlag[i]` is set equal to 0 for all values of `i` from 1 to `vps_max_layer_id`, inclusive, and the variable `FirstPicInLayerDecodedFlag[i]` is set equal to 0 for all values of `i` from 1 to `vps_max_layer_id`, inclusive.

F.8.1.9 Decoding process for an external base layer picture

The following applies for the decoded picture with `nuh_layer_id` equal to 0 for the access unit:

- `TemporalId` and `PicOrderCntVal` of the decoded picture with `nuh_layer_id` equal to 0 are set equal to the `TemporalId` and `PicOrderCntVal`, respectively, of any picture with `nuh_layer_id` greater than 0 in the access unit.

NOTE – The constraint on the value of `TemporalId` being required to be equal to 0 for IRAP pictures also applies to pictures with `nuh_layer_id` equal to 0 when `vps_base_layer_internal_flag` is equal to 0.
- The decoded picture with `nuh_layer_id` equal to 0 is stored in the sub-DPB for the layer with `nuh_layer_id` equal to 0 and is marked as "used for long-term reference".

F.8.2 NAL unit decoding process

The specifications in clause 8.2 apply.

F.8.3 Slice decoding processes

F.8.3.1 Decoding process for picture order count

Output of this process is `PicOrderCntVal`, the picture order count of the current picture.

Picture order counts are used to identify pictures, for deriving motion parameters in merge mode and motion vector prediction and for decoder conformance checking (see clause F.13.5).

Each coded picture is associated with a picture order count variable, denoted as `PicOrderCntVal`.

When the current picture is the first picture among all layers of a POC resetting period, the variable `PocDecrementInDPBFlag[i]` is set equal to 0 for each value of `i` in the range of 0 to 62, inclusive.

The variable `pocResetFlag` is derived as follows:

- If the current picture is a POC resetting picture, the following applies:
 - If `vps_poc_lsb_aligned_flag` is equal to 0, `pocResetFlag` is set equal to 1.
 - Otherwise, if `PocDecrementInDPBFlag[nuh_layer_id]` is equal to 1, `pocResetFlag` is set equal to 0.
 - Otherwise, `pocResetFlag` is set equal to 1.
- Otherwise, `pocResetFlag` is set equal to 0.

The list `affectedLayerList` is derived as follows:

- If `vps_poc_lsb_aligned_flag` is equal to 0, `affectedLayerList` consists of the `nuh_layer_id` of the current picture.
- Otherwise, `affectedLayerList` consists of the `nuh_layer_id` of the current picture and the `nuh_layer_id` values equal to `IdPredictedLayer[currNuhLayerId][j]` for all values of `j` in the range of 0 to `NumPredictedLayers[currNuhLayerId] – 1`, inclusive, where `currNuhLayerId` is the `nuh_layer_id` value of the current picture.

Depending on `pocResetFlag`, the following applies:

- If `pocResetFlag` is equal to 1, the following applies:
 - When `FirstPicInLayerDecodedFlag[nuh_layer_id]` is equal to 1, the following applies:
 - The variables `pocMsbDelta`, `pocLsbDelta` and `DeltaPocVal` are derived as follows:

```

              if( poc_reset_idc == 3 )
                pocLsbVal = poc_lsb_val
              else
                pocLsbVal = slice_pic_order_cnt_lsb
              if( poc_msb_cycle_val_present_flag )
                pocMsbDelta = poc_msb_cycle_val * MaxPicOrderCntLsb
              else {
                prevPicOrderCntLsb = PrevPicOrderCnt[ nuh_layer_id ] & ( MaxPicOrderCntLsb – 1 )
                prevPicOrderCntMsb = PrevPicOrderCnt[ nuh_layer_id ] – prevPicOrderCntLsb
                pocMsbDelta = GetCurrMsb( pocLsbVal, prevPicOrderCntLsb, prevPicOrderCntMsb,
                                      MaxPicOrderCntLsb )
              }
              if( poc_reset_idc == 2 || ( poc_reset_idc == 3 && full_poc_reset_flag ) )
                pocLsbDelta = pocLsbVal
              else
                pocLsbDelta = 0
              DeltaPocVal = pocMsbDelta + pocLsbDelta
              
```

(F-60)
 - The `PicOrderCntVal` of each picture that has `nuh_layer_id` value `nuhLayerId` for which `PocDecrementInDPBFlag[nuhLayerId]` is equal to 0 and that is equal to any value in `affectedLayerList` is decremented by `DeltaPocVal`.
 - `PocDecrementInDPBFlag[nuhLayerId]` is set equal to 1 for each value of `nuhLayerId` included in `affectedLayerList`.
- The `PicOrderCntVal` of the current picture is derived as follows:

```

      if( poc_reset_idc == 1 )
        PicOrderCntVal = slice_pic_order_cnt_lsb
      else if( poc_reset_idc == 2 )
        PicOrderCntVal = 0
      else {

```

$$\begin{aligned}
 \text{PicOrderCntMsb} &= \text{GetCurrMsb}(\text{slice_pic_order_cnt_lsb}, \text{full_poc_reset_flag} ? 0 : \text{poc_lsb_val}, \\
 &\quad 0, \text{MaxPicOrderCntLsb}) \\
 \text{PicOrderCntVal} &= \text{PicOrderCntMsb} + \text{slice_pic_order_cnt_lsb} \\
 &\}
 \end{aligned}
 \tag{F-61}$$

- Otherwise (pocResettingFlag is equal to 0), the following applies:
 - The PicOrderCntVal of the current picture is derived as follows:

$$\begin{aligned}
 &\text{if}(\text{poc_msb_cycle_val_present_flag}) \\
 &\quad \text{PicOrderCntMsb} = \text{poc_msb_cycle_val} * \text{MaxPicOrderCntLsb} \\
 &\text{else if}(\text{!FirstPicInLayerDecodedFlag}[\text{nuh_layer_id}] \mid \mid \\
 &\quad \text{nal_unit_type} == \text{IDR_N_LP} \mid \mid \text{nal_unit_type} == \text{IDR_W_RADL}) \\
 &\quad \text{PicOrderCntMsb} = 0 \\
 &\text{else} \{ \\
 &\quad \text{prevPicOrderCntLsb} = \text{PrevPicOrderCnt}[\text{nuh_layer_id}] \& (\text{MaxPicOrderCntLsb} - 1) \\
 &\quad \text{prevPicOrderCntMsb} = \text{PrevPicOrderCnt}[\text{nuh_layer_id}] - \text{prevPicOrderCntLsb} \\
 &\quad \text{PicOrderCntMsb} = \text{GetCurrMsb}(\text{slice_pic_order_cnt_lsb}, \text{prevPicOrderCntLsb}, \\
 &\quad \quad \text{prevPicOrderCntMsb}, \text{MaxPicOrderCntLsb}) \\
 &\} \\
 &\text{PicOrderCntVal} = \text{PicOrderCntMsb} + \text{slice_pic_order_cnt_lsb}
 \end{aligned}
 \tag{F-62}$$

The value of PrevPicOrderCnt[Ild] for each of the Ild values included in affectedLayerList is derived as follows:

- If the current picture is not a RASL, RADL or SLNR picture, and the current picture has TemporalId equal to 0 and discardable_flag equal to 0, PrevPicOrderCnt[Ild] is set equal to PicOrderCntVal.
- Otherwise, when poc_reset_idc is equal to 3 and one of the following conditions is true, PrevPicOrderCnt[Ild] is set equal to (full_poc_reset_flag ? 0 : poc_lsb_val):
 - FirstPicInLayerDecodedFlag[nuh_layer_id] is equal to 0.
 - FirstPicInLayerDecodedFlag[nuh_layer_id] is equal to 1 and the current picture is a POC resetting picture.

The value of PicOrderCntVal shall be in the range of -2^{31} to $2^{31} - 1$, inclusive.

It is a requirement of bitstream conformance that the current PicOrderCntVal values of any two pictures in the same layer and the same CVS shall not be the same.

NOTE 1 – PicOrderCntVal, as derived in this clause for the current picture, may be equal to initialPocVal, where initialPocVal is the PicOrderCntVal derived by this clause when an earlier picture, in decoding order, with nuh_layer_id equal to currNuhLayerId in the current CVS, was the current picture. However, the decoding processes applied subsequently have updated the PicOrderCntVal value for that earlier picture so that it no longer is equal to the PicOrderCntVal value derived in this clause for the current picture.

The function PicOrderCnt(picX) is specified as follows:

$$\text{PicOrderCnt}(\text{picX}) = \text{PicOrderCntVal of the picture picX}
 \tag{F-63}$$

The function DiffPicOrderCnt(picA, picB) is specified as follows:

$$\text{DiffPicOrderCnt}(\text{picA}, \text{picB}) = \text{PicOrderCnt}(\text{picA}) - \text{PicOrderCnt}(\text{picB})
 \tag{F-64}$$

The bitstream shall not contain data that result in values of DiffPicOrderCnt(picA, picB) used in the decoding process that are not in the range of -2^{15} to $2^{15} - 1$, inclusive.

NOTE 2 – Let X be the current picture and Y and Z be two other pictures in the same sequence, Y and Z are considered to be in the same output order direction from X when both DiffPicOrderCnt(X, Y) and DiffPicOrderCnt(X, Z) are positive or both are negative.

F.8.3.2 Decoding process for reference picture set

The specifications in clause 8.3.2 apply with the following changes:

- The references to clauses 7.4.7.2, 8.3.1, 8.3.3 and 8.3.4 are replaced with references to clauses F.7.4.7.2, F.8.3.1, F.8.3.3 and F.8.3.4, respectively.
- The following specifications are added:

- When the current picture is an IRAP picture with `nuh_layer_id` equal to `SmallestLayerId`, all reference pictures with any value of `nuh_layer_id` currently in the DPB (if any) are marked as "unused for reference" when at least one of the following conditions is true:
 - The current picture has `NoClasOutputFlag` is equal to 1.
 - The current picture activates a new VPS.
- It is a requirement of bitstream conformance that the RPS is restricted as follows:
 - When the current picture is a CRA picture, there shall be no picture in `RefPicSetStCurrBefore`, `RefPicSetStCurrAfter` or `RefPicSetLtCurr`.
- The constraints specified in clause 8.3.2 on the value of `NumPicTotalCurr` are replaced with the following:
 - It is a requirement of bitstream conformance that the following applies to the value of `NumPicTotalCurr`:
 - If the current picture is a BLA or CRA picture and either `currPicLayerId` is equal to 0 or `NumDirectRefLayers[currPicLayerId]` is equal to 0, the value of `NumPicTotalCurr` shall be equal to `pps_curr_pic_ref_enabled_flag`.
 - Otherwise, when the current picture contains a P or B slice, the value of `NumPicTotalCurr` shall not be equal to 0.
- The constraint, specified in clause 8.3.2, that requires no entry in `RefPicSetStCurrBefore`, `RefPicSetStCurrAfter`, or `RefPicSetLtCurr` when one or more of three conditions are true is replaced with the following:
 - There shall be no entry in `RefPicSetStCurrBefore`, `RefPicSetStCurrAfter`, or `RefPicSetLtCurr` for which one or more of the following are true:
 - The entry is equal to "no reference picture" and `FirstPicInLayerDecodedFlag[currPicLayerId]` is equal to 1.
 - The entry is an SLNR picture and has `TemporalId` equal to that of the current picture.
 - The entry is a picture that has `TemporalId` greater than that of the current picture.

F.8.3.3 Decoding process for generating unavailable reference pictures

The specifications in clause 8.3.3 and its subclauses apply with the replacement of references to Annex C with references to clause F.13.

F.8.3.4 Decoding process for reference picture lists construction

This process is invoked at the beginning of the decoding process for each P or B slice.

Reference pictures are addressed through reference indices as specified in clause 8.5.3.3.2. A reference index is an index into a reference picture list. When decoding a P slice, there is a single reference picture list `RefPicList0`. When decoding a B slice, there is a second independent reference picture list `RefPicList1` in addition to `RefPicList0`.

At the beginning of the decoding process for each slice, the reference picture lists `RefPicList0` and, for B slices, `RefPicList1` are derived as follows:

If `TwoVersionsOfCurrDecPicFlag` is equal to 1, let the variable `currPic` be the current decoded picture before the invocation of the in-loop filter process; otherwise (`TwoVersionsOfCurrDecPicFlag` is equal to 0), let the variable `currPic` be the current decoded picture after the invocation of the in-loop filter process. The variable `NumRpsCurrTempList0` is set equal to `Max(num_ref_idx_l0_active_minus1 + 1, NumPicTotalCurr)` and the list `RefPicListTemp0` is constructed as follows:

```

rIdx = 0
while( rIdx < NumRpsCurrTempList0 ) {
  for( i = 0; i < NumPocStCurrBefore && rIdx < NumRpsCurrTempList0; rIdx++, i++ )
    RefPicListTemp0[ rIdx ] = RefPicSetStCurrBefore[ i ]
  for( i = 0; i < NumActiveRefLayerPics0; rIdx++, i++ )
    RefPicListTemp0[ rIdx ] = RefPicSetInterLayer0[ i ]
  for( i = 0; i < NumPocStCurrAfter && rIdx < NumRpsCurrTempList0; rIdx++, i++ )      (F-65)
    RefPicListTemp0[ rIdx ] = RefPicSetStCurrAfter[ i ]
  for( i = 0; i < NumPocLtCurr && rIdx < NumRpsCurrTempList0; rIdx++, i++ )
    RefPicListTemp0[ rIdx ] = RefPicSetLtCurr[ i ]
  for( i = 0; i < NumActiveRefLayerPics1; rIdx++, i++ )
    RefPicListTemp0[ rIdx ] = RefPicSetInterLayer1[ i ]
  if( pps_curr_pic_ref_enabled_flag )

```

```

        RefPicListTemp0[ rIdx++ ] = currPic
    }

```

The list RefPicList0 is constructed as follows:

```

for( rIdx = 0; rIdx <= num_ref_idx_l0_active_minus1; rIdx++ )
    RefPicList0[ rIdx ] = ref_pic_list_modification_flag_l0 ? RefPicListTemp0[ list_entry_l0[ rIdx ] ] :
                                                                    RefPicListTemp0[ rIdx ]
if( pps_curr_pic_ref_enabled_flag && !ref_pic_list_modification_flag_l0 &&
    NumRpsCurrTempList0 > ( num_ref_idx_l0_active_minus1 + 1 ) )
    RefPicList0[ num_ref_idx_l0_active_minus1 ] = currPic

```

(F-66)

When the slice is a B slice, the variable NumRpsCurrTempList1 is set equal to Max(num_ref_idx_l1_active_minus1 + 1, NumPicTotalCurr) and the list RefPicListTemp1 is constructed as follows:

```

rIdx = 0
while( rIdx < NumRpsCurrTempList1 ) {
    for( i = 0; i < NumPocStCurrAfter && rIdx < NumRpsCurrTempList1; rIdx++, i++ )
        RefPicListTemp1[ rIdx ] = RefPicSetStCurrAfter[ i ]
    for( i = 0; i < NumActiveRefLayerPics1; rIdx++, i++ )
        RefPicListTemp1[ rIdx ] = RefPicSetInterLayer1[ i ]
    for( i = 0; i < NumPocStCurrBefore && rIdx < NumRpsCurrTempList1; rIdx++, i++ )
        RefPicListTemp1[ rIdx ] = RefPicSetStCurrBefore[ i ]
    for( i = 0; i < NumPocLtCurr && rIdx < NumRpsCurrTempList1; rIdx++, i++ )
        RefPicListTemp1[ rIdx ] = RefPicSetLtCurr[ i ]
    for( i = 0; i < NumActiveRefLayerPics0; rIdx++, i++ )
        RefPicListTemp1[ rIdx ] = RefPicSetInterLayer0[ i ]
    if( pps_curr_pic_ref_enabled_flag )
        RefPicListTemp1[ rIdx++ ] = currPic
}

```

(F-67)

When the slice is a B slice, the list RefPicList1 is constructed as follows:

```

for( rIdx = 0; rIdx <= num_ref_idx_l1_active_minus1; rIdx++ )
    RefPicList1[ rIdx ] = ref_pic_list_modification_flag_l1 ? RefPicListTemp1[ list_entry_l1[ rIdx ] ] :
                                                                RefPicListTemp1[ rIdx ]

```

(F-68)

It is a requirement of bitstream conformance that when the current layer is an independent non-base layer, nal_unit_type has a value in the range of BLA_W_LP to RSV_IRAP_VCL23, inclusive (i.e. the picture is an IRAP picture), pps_curr_pic_ref_enabled_flag is equal to 1, and slice_type is not equal to 2, RefPicList0 and RefPicList1 shall not contain entries that refer to a picture other than the current picture.

F.8.4 Decoding process for coding units coded in intra prediction mode

The specifications in clause 8.4 and its subclauses apply.

F.8.5 Decoding process for coding units coded in inter prediction mode

The specifications in clause 8.5 and its subclauses apply.

F.8.6 Scaling, transformation and array construction process prior to deblocking filter process

The specifications in clause 8.6 and its subclauses apply.

F.8.7 In-loop filter process

The specifications in clause 8.7 and its subclauses apply.

F.9 Parsing process

The specifications in clause 9 and its subclauses apply.

F.10 Specification of bitstream subsets

F.10.1 Sub-bitstream extraction process

Inputs to this process are a bitstream `inBitstream`, a target highest TemporalId value `tIdTarget` and a target layer identifier list `layerIdListTarget`.

Output of this process is a sub-bitstream `outBitstream`.

When `vps_base_layer_internal_flag` is equal to 1 and `vps_base_layer_available_flag` is equal to 1, it is a requirement of bitstream conformance for `inBitstream` that any output sub-bitstream `outBitstream` that is the output of the process specified in this clause with `inBitstream`, `tIdTarget` equal to any value in the range of 0 to 6, inclusive, and `layerIdListTarget` equal to the layer identifier list associated with a layer set specified in the active VPS as inputs, and that satisfies both of the following conditions shall be a conforming bitstream:

- The output sub-bitstream contains at least one VCL NAL unit with `nuh_layer_id` equal to each of the `nuh_layer_id` values in `layerIdListTarget`.
- The output sub-bitstream contains at least one VCL NAL unit with TemporalId equal to `tIdTarget`.

NOTE 1 – When `vps_base_layer_internal_flag` is equal to 1 and `vps_base_layer_available_flag` is equal to 1, a conforming bitstream contains one or more coded slice segment NAL units with `nuh_layer_id` equal to 0 and TemporalId equal to 0.

The output sub-bitstream `outBitstream` is derived as follows:

- The bitstream `outBitstream` is set to be identical to the bitstream `inBitstream`.
- When one or more of the following two conditions are true, remove from `outBitstream` all SEI NAL units that have `nuh_layer_id` equal to 0 and that contain a non-scalable-nested buffering period SEI message, a non-scalable-nested picture timing SEI message, or a non-scalable-nested decoding unit information SEI message:
 - `layerIdListTarget` does not include all the values of `nuh_layer_id` in all NAL units in the bitstream.
 - `tIdTarget` is less than the greatest TemporalId in all NAL units in the bitstream.

NOTE 2 – A "smart" bitstream extractor may include appropriate non-scalable-nested buffering picture SEI messages, non-scalable-nested picture timing SEI messages and non-scalable-nested decoding unit information SEI messages in the extracted sub-bitstream, provided that the SEI messages applicable to the sub-bitstream were present as scalable-nested SEI messages in the original bitstream.

- Remove from `outBitstream` all NAL units with TemporalId greater than `tIdTarget` or `nuh_layer_id` not among the values included in `layerIdListTarget`.

F.10.2 Independent non-base layer rewriting process

Inputs to this process are a bitstream `inBitstream`, a target highest TemporalId value `tIdTarget` and a `nuh_layer_id` value `assignedBaseLayerId` of an independent non-base layer of an additional layer set.

Output of this process is a sub-bitstream `outBitstream`.

It is a requirement of bitstream conformance for `inBitstream` that any output sub-bitstream `outBitstream` that is the output of the process specified in this clause shall otherwise be a conforming bitstream except that `outBitstream` does not contain any VPS NAL units, when all of the following conditions apply:

- The output sub-bitstream `outBitstream` contains VCL NAL units with `nuh_layer_id` equal to `assignedBaseLayerId`.
- The value of `tIdTarget` is equal to any value in the range of 0 to 6, inclusive, and `outBitstream` contains at least one VCL NAL unit with TemporalId equal to `tIdTarget`.
- There is an OLS in the active VPS that consists of only the layer with `nuh_layer_id` equal to `assignedBaseLayerId`, the profile of that layer is a profile specified in Annex A and the value of `general_inbld_flag` (when `tIdTarget` is equal to `vps_max_sub_layers_minus1`) or the value of `sub_layer_inbld_flag[tIdTarget]` (when `tIdTarget` is less than `vps_max_sub_layers_minus1`) in the `profile_tier_level()` syntax structure associated with that layer is equal to 1.

The output sub-bitstream `outBitstream` is derived from the bitstream `inBitstream` as follows:

- The bitstream `outBitstream` is set to be identical to the bitstream `inBitstream`.
- NAL units with `nal_unit_type` not equal to `SPS_NUT`, `PPS_NUT`, and `EOB_NUT` and with `nuh_layer_id` not equal to the `assignedBaseLayerId` are removed from `outBitstream`.
- NAL units with `nal_unit_type` equal to `SPS_NUT` or `PPS_NUT` with `nuh_layer_id` not equal to 0 or `assignedBaseLayerId` are removed from `outBitstream`.
- NAL units with `nal_unit_type` equal to `VPS_NUT` are removed from `outBitstream`.

- All NAL units with TemporalId greater than tIdTarget are removed from outBitstream.
- nuh_layer_id is set equal to 0 in each NAL unit of outBitstream.

F.10.3 Sub-bitstream extraction process for additional layer sets

Inputs to this process are a bitstream inBitstream, a target highest TemporalId value tIdTarget and a target layer identifier list layerIdListTarget of an additional layer set.

Output of this process is a sub-bitstream outBitstream.

It is a requirement of bitstream conformance for the input bitstream that the output sub-bitstream of the process specified in this clause shall be a conforming bitstream according to at least one profile in which vps_base_layer_available_flag may be equal to 0, when all of the following conditions apply:

- The output sub-bitstream outBitstream contains VCL NAL units with each nuh_layer_id value in layerIdListTarget.
- The value of tIdTarget is equal to any value in the range of 0 to 6, inclusive, and outBitstream contains at least one VCL NAL unit with TemporalId equal to tIdTarget.
- layerIdListTarget is identical to LayerSetLayerIdList[i] for any value of i in the range of FirstAddLayerSetIdx to LastAddLayerSetIdx, inclusive.

The output sub-bitstream outBitstream is derived as follows:

- The bitstream outBitstream is set to be identical to the bitstream inBitstream.
- NAL units with nal_unit_type not equal to VPS_NUT, SPS_NUT, PPS_NUT, EOS_NUT and EOB_NUT and with nuh_layer_id not equal to any value in layerIdListTarget are removed from outBitstream.
- NAL units with nal_unit_type equal to VPS_NUT, SPS_NUT, PPS_NUT or EOS_NUT with nuh_layer_id not equal to 0 or any value in layerIdListTarget are removed from outBitstream.
- All NAL units with TemporalId greater than tIdTarget are removed from outBitstream.
- vps_base_layer_available_flag in each VPS is set equal to 0.

F.11 Profiles, tiers and levels

F.11.1 Independent non-base layer decoding capability

This clause specifies the independent non-base layer decoding (INBLD) capability, which is associated with the decoding capability of one or more of the profiles specified in Annex A. When expressing the capabilities of a decoder for one or more profiles specified in Annex A, whether the INBLD capability is supported for those profiles should also be expressed.

NOTE 1– The INBLD capability, when supported, indicates the capability of a decoder to decode an independent non-base layer that is indicated in the active VPSs and SPSs to conform to a profile specified in Annex A and is the layer with the smallest nuh_layer_id value in an additional layer set.

When the profile_tier_level() syntax structure is used for indicating of a decoder capability in systems, the INBLD capability may be indicated by setting the general_inbld_flag equal to 1 in the profile_tier_level() syntax structure used to express the profile, tier and level that the decoder conforms to.

general_inbld_flag is set equal to 1 in the profile_tier_level() syntax structures in which a profile specified in Annex A is indicated and which are either specified in the VPS to be applicable for a non-base layer or included in an SPS activated for an independent non-base layer.

Decoders having the INBLD capability and conforming to a specific profile specified in Annex A at a specific level of a specific tier shall be capable of decoding any independent non-base layer or a sub-layer representation with TemporalId equal to i of the independent non-base layer for which all of the following condition applies for each active VPS:

- There is an OLS that consists of the independent non-base layer and for which the associated profile_tier_level() syntax structure ptlStruct is constrained as follows:
 - ptlStruct indicates that the independent non-base layer or the sub-layer representation conforms to a profile specified in Annex A.
 - ptlStruct indicates that the independent non-base layer or the sub-layer representation conforms to a level lower than or equal to the specified level.
 - ptlStruct indicates that the independent non-base layer or the sub-layer representation conforms to a tier lower than or equal to the specified tier.
 - general_inbld_flag or sub_layer_inbld_flag[i] in ptlStruct is equal to 1.

NOTE 2– Let a derived bitstream `outBitstream` be a bitstream which is derived by invoking the independent non-base layer rewriting process specified in clause F.10.2 with a bitstream containing one or more independent non-base layers, `tldTarget` equal to 6 and `assignedBaseLayerId` equal to the smallest `nuh_layer_id` value of additional layer set as inputs. As specified elsewhere in this Specification, it is a requirement of bitstream conformance that `outBitstream` is otherwise a conforming bitstream but does not contain VPSs. Consequently, decoders with INBLD capability may apply the independent non-base layer rewriting process specified in clause F.10.2 to obtain `outBitstream` and then apply a decoding process for a profile specified in Annex A with `outBitstream` as input.

NOTE 3– The following constraints are necessary to ensure that a sub-bitstream derived by invoking the independent non-base layer rewriting process specified in clause F.10.2 conforms to a profile specified in Annex A:

- All active SPSs for the independent non-base layer have `nuh_layer_id` equal to 0 or `MultiLayerExtSpsFlag` equal to 0.
- Each active VPS has `poc_lsb_not_present_flag[i]` equal to 1 for each value of `i` for which `i` is the layer index of the independent non-base layer.

F.11.2 Decoder capabilities

This clause specifies requirements for decoders having the capability of decoding an output operation point with one or more necessary layers.

NOTE – For example, this clause specifies the requirements for a decoder supporting simultaneous decoding of the base layer and an independent non-base layer for which the INBLD capability is needed. Moreover, this clause specifies the requirements for a decoder supporting decoding of layers conforming to profiles specified in Annex G or H.

A decoder that conforms to a list `ptliList` consisting of profile, tier, level and INBLD capability quadruplets (`Pi`, `Ti`, `Li`, `InbldFlagi`) for `i` in the range of 0 to `d – 1`, inclusive, where `d` is a positive integer, shall be capable of decoding any output operation point containing `b` necessary layers, where `b` is less than or equal to `d`, when the following condition applies:

- There exists a reordered list, `orderedPtliList`, of the profile, tier, level and INBLD capability quadruplets (`orderedPj`, `orderedTj`, `orderedLj`, `orderedInbldFlagj`) of the list `ptliList` such that all the following conditions apply for each value of `j` in the range of 0 to `b – 1`, inclusive, where the variable `bLayer[j]` represents the `j`-th necessary layer in the output operation point:
 - The profile to which `bLayer[j]` is indicated to conform is included in `CompatibleProfileList` for the profile `orderedPj` as specified in Table F.3.
 - The tier to which `bLayer[j]` is indicated to conform is lower than or equal to the tier `orderedTj`.
 - The level to which `bLayer[j]` is indicated to conform is lower than or equal to the level `orderedLj`.
 - When the profile to which `bLayer[j]` is indicated to conform is a profile specified in Annex A, the value of `general_inbld_flag` (when `OpTid` of the output operation point is equal to `vps_max_sub_layers_minus1`) or `sub_layer_inbld_flag[OpTid]` (when `OpTid` of the output operation point is less than `vps_max_sub_layers_minus1`) of `bLayer[j]` is less than or equal to `orderedInbldFlagj`.

For each particular format range extensions profile specified in clause A.3.5, the compatible format range extensions profiles are defined as the profiles that are indicated by both of the following conditions being true:

- The value of `general_profile_idc` is equal to 4 or `general_profile_compatibility_flag[4]` is equal to 1.
- The value of each constraint flag listed in Table A.2 is less than or equal to the corresponding value specified in the row of Table A.2 for the particular format range extensions profile.

For each particular scalable format range extensions profile specified in clause H.11.1.2, the compatible scalable format range extensions profiles are defined as the profiles that are indicated by all of the following conditions being true:

- The value of `general_profile_idc` is equal to 10 or `general_profile_compatibility_flag[10]` is equal to 1.
- The value of each constraint flag listed in Table H.4 is less than or equal to the corresponding value specified in the row of Table H.4 for the particular scalable format range extensions profile.

Table F.3 – Specification of CompatibleProfileList

Profile to which the decoder conforms	Profiles that the decoder shall support CompatibleProfileList
Scalable Main	Scalable Main, Main, Main Still Picture
Scalable Main 10	Scalable Main 10, Main, Main Still Picture, Main 10, Scalable Main
Scalable Monochrome	The compatible format range extensions profiles of the Monochrome profile, and the compatible scalable format range extensions profiles of the Scalable Monochrome profile
Scalable Monochrome 12	The compatible format range extensions profiles of the Monochrome 12 profile, and the compatible scalable format range extensions profiles of the Scalable Monochrome 12 profile
Scalable Monochrome 16	The compatible format range extensions profiles of the Monochrome 16 profile, and the compatible scalable format range extensions profiles of the Scalable Monochrome 16 profile
Scalable Main 4:4:4	Scalable Main, Main, Main Still Picture, the compatible format range extensions profiles of the Main 4:4:4 profile, and the compatible scalable format range extensions profiles of the Scalable Main 4:4:4 profile
Multiview Main	Multiview Main, Main, Main Still Picture
3D Main	3D Main, Multiview Main, Main, Main Still Picture

F.11.3 Derivation of sub-bitstreams subBitstream and baseBitstream

For an output operation point associated with an OLS in a bitstream, let `olsIdx` be the OLS index of the OLS, the sub-bitstream `subBitstream` and base layer sub-bitstream `baseBitstream` are derived as follows:

- The sub-bitstream `subBitstream` is derived as follows:
 - If `OlsIdxToLsIdx[olsIdx]` is less than or equal to `vps_num_layer_sets_minus1`, `subBitstream` is derived by invoking the sub-bitstream extraction process as specified in clause F.10.1 with the following inputs: the bitstream, `tIdTarget` equal to `OpTid` of the output operation point, and `layerIdListTarget` containing the `nuh_layer_id` value `layerId` of the layer and all the reference layers of the layer.
 - Otherwise, `subBitstream` is derived by invoking the sub-bitstream extraction process as specified in clause F.10.3 with `tIdTarget` equal to `OpTid` of the output operation point and with `layerIdListTarget` containing the `nuh_layer_id` value of the layer and all the reference layers of the layer.
- When `vps_base_layer_internal_flag` is equal to 1, the base layer sub-bitstream `baseBitstream` is derived as follows:
 - If VCL NAL units with `nuh_layer_id` equal to 0 are included in `subBitstream`, `baseBitstream` is derived by invoking the sub-bitstream extraction process as specified in clause F.10.1 with the `subBitstream`, `tIdTarget` equal to `OpTid` of the output operation point, and `layerIdListTarget` containing only one `nuh_layer_id` value that is equal to 0 as inputs.
 - Otherwise, `baseBitstream` is derived by invoking the independent non-base layer rewriting process as specified in clause F.10.2 with `subBitstream`, `tIdTarget` equal to `OpTid` of the output operation point, and `layerIdListTarget` containing only the smallest `nuh_layer_id` value of the VCL NAL units of `subBitstream` as inputs.

F.12 Byte stream format

The specifications in Annex B apply.

F.13 Hypothetical reference decoder

F.13.1 General

Three sets of bitstream conformance tests are needed for checking the conformance of a bitstream, which is referred to as the entire bitstream, denoted as `entireBitstream`. The first set of bitstream conformance tests are for testing the conformance of the entire bitstream and its temporal subsets, regardless of whether there is a layer set specified by the active VPS that contains all the `nuh_layer_id` values of VCL NAL units present in the entire bitstream. The second set of bitstream

conformance tests are for testing the conformance of the layer sets specified by the active VPS and their temporal subsets. For all these tests, only the base layer pictures (i.e., pictures with `nuh_layer_id` equal to 0) are decoded and other pictures are ignored by the decoder when the decoding process is invoked.

The first and second sets of bitstream conformance tests are specified in clause C.1. Clause F.13 and its subclauses specify the HRD operations for the third sets of bitstream conformance tests.

The third set of bitstream conformance tests are for testing the conformance of the OLSs specified by the VPS extension part of the active VPS and their temporal subsets. For each test in the third set of bitstream conformance tests, the following ordered steps apply in the order listed, followed by the processes described after these steps in this clause:

1. An output operation point under test, denoted as `TargetOp`, is selected by selecting a value for `TargetOlsIdx` identifying a target OLS and selecting a target highest TemporalId value `HighestTid`. The value of `TargetOlsIdx` shall be in the range of 0 to `NumOutputLayerSets - 1`, inclusive, and the value of `HighestTid` shall be in the range of 0 to `MaxSubLayersInLayerSetMinus1[OlsIdxToLsIdx[TargetOlsIdx]]`, inclusive. Additionally, the values of `TargetOlsIdx` and `HighestTid` are constrained as specified in the next step.

The variables `TargetDecLayerSetIdx`, `TargetOptLayerIdList`, and `TargetDecLayerIdList` are then derived as specified in clause F.8.1.2. The output operation point under test has `OptLayerIdList` equal to `TargetOptLayerIdList`, `OpLayerIdList` equal to `TargetDecLayerIdList` and `OpTid` equal to `HighestTid`.

2. A bitstream to be decoded, `BitstreamToDecode`, is specified as follows:
 - If `TargetDecLayerSetIdx` is less than or equal to `vps_num_layer_sets_minus1` and `vps_base_layer_internal_flag` is equal to 1, the sub-bitstream extraction process as specified in clause 10 is applied with the bitstream `entireBitstream`, `HighestTid` and `TargetDecLayerIdList` as inputs, and the output is assigned to `BitstreamToDecode`.
 - Otherwise, if `TargetDecLayerSetIdx` is less than or equal to `vps_num_layer_sets_minus1` and `vps_base_layer_internal_flag` is equal to 0, the sub-bitstream extraction process as specified in clause F.10.1 is applied with the bitstream `entireBitstream`, `HighestTid` and `TargetDecLayerIdList` as inputs, and the output is assigned to `BitstreamToDecode`.
 - Otherwise, if `TargetDecLayerSetIdx` is greater than `vps_num_layer_sets_minus1`, `NumLayersInIdList[TargetDecLayerSetIdx]` is equal to 1 and the profile of the layer in `TargetOlsIdx` is one of those specified in Annex A, the independent non-base layer rewriting process of clause F.10.2 is applied with the bitstream `entireBitstream`, `HighestTid` and `TargetDecLayerIdList[0]` as inputs, and the output is assigned to `BitstreamToDecode`.
 - Otherwise, the sub-bitstream extraction process as specified in clause F.10.3 is applied with the bitstream `entireBitstream`, `HighestTid` and `TargetDecLayerIdList` as inputs, and the output is assigned to `BitstreamToDecode`.

The values of `TargetOlsIdx` and `HighestTid` are additionally constrained as follows:

- When `vps_base_layer_available_flag` is equal to 0, `OlsIdxToLsIdx[TargetOlsIdx]` shall be in the range of `FirstAddLayerSetIdx` to `LastAddLayerSetIdx`, inclusive.
 - When `vps_base_layer_internal_flag` is equal to 0, `TargetOlsIdx` shall be greater than 0.
 - The value of `TargetOlsIdx` shall be such that there is at least one VCL NAL unit in `BitstreamToDecode` with `nuh_layer_id` equal to `LayerSetLayerIdList[OlsIdxToLsIdx[TargetOlsIdx]][i]` for each value of `i` in the range of 0 to `NumLayersInIdList[OlsIdxToLsIdx[TargetOlsIdx]] - 1`, inclusive.
 - The value of `HighestTid` shall be such that there is at least one VCL NAL unit with TemporalId equal to `HighestTid` in `BitstreamToDecode`.
3. A partitioning scheme is selected from the list of partitioning schemes signalled in the active VPS for the selected OLS. The selected partitioning scheme is denoted as `TargetPartitioningScheme` with partitioning scheme index `TargetPsIdx`.
 4. The subsequent steps apply to each bitstream partition, referred to as the bitstream partition under test `TargetBitstreamPartition`, of the selected partitioning scheme of the target OLS. If there is only one bitstream partition for `TargetPartitioningScheme`, the `TargetBitstreamPartition` is identical to `BitstreamToDecode`. Otherwise, each bitstream partition is derived with the demultiplexing process for deriving a bitstream partition in clause F.13.6, with `BitstreamToDecode`, the list of layers in `TargetBitstreamPartition` and the number of layers in `TargetBitstreamPartition` as inputs.
 5. The applicable `hrd_parameters()` syntax structures and the `sub_layer_hrd_parameters()` syntax structures are selected as follows:
 - A `SchedSelCombIdx` is selected for `BitstreamToDecode` and used for each `TargetBitstreamPartition`. The selected `SchedSelCombIdx` shall be in the range of 0 to `num_bsp_schedules_minus1[TargetOlsIdx][TargetPsIdx][HighestTid]`, inclusive.

- The applicable `hrd_parameters()` syntax structure is the `bsp_hrd_idx[TargetOlsIdx][TargetPsIdx][HighestTid][SchedSelCombIdx][j]`-th `hrd_parameters()` syntax structure in the active VPS, where `j` is the bitstream partition index of `TargetBitstreamPartition`.

Within the selected `hrd_parameters()` syntax structures, if `BitstreamToDecode` is a Type I bitstream, the `sub_layer_hrd_parameters(HighestTid)` syntax structures that immediately follow the condition "`if(vcl_hrd_parameters_present_flag)`" are selected and the variable `NalHrdModeFlag` is set equal to 0; otherwise (`BitstreamToDecode` is a Type II bitstream), the `sub_layer_hrd_parameters(HighestTid)` syntax structures that immediately follow either the condition "`if(vcl_hrd_parameters_present_flag)`" (in this case the variable `NalHrdModeFlag` is set equal to 0) or the condition "`if(nal_hrd_parameters_present_flag)`" (in this case the variable `NalHrdModeFlag` is set equal to 1) are selected. When `BitstreamToDecode` is a Type II bitstream and `NalHrdModeFlag` is equal to 0, all non-VCL NAL units except filler data NAL units, and all leading `zero_8bits`, `zero_byte`, `start_code_prefix_one_3bytes`, and `trailing_zero_8bits` syntax elements that form a byte stream from the NAL unit stream (as specified in Annex B), when present, are discarded from `TargetBitstreamPartition`, and the remaining sub-bitstream is assigned to `TargetBitstreamPartition`.

6. An access unit associated with a buffering period SEI message (present in a bitstream partition nesting SEI message in `BitstreamToDecode` or available through external means not specified in this Specification) applicable to `TargetOp`, `TargetPartitioningScheme` and `TargetBitstreamPartition` is selected as the HRD initialization point and referred to as access unit 0.

The variable `MultiLayerCpbOperationFlag` is derived as follows:

- If `BitstreamToDecode` contains only the base layer (i.e., `TargetOlsIdx` is equal to 0), `MultiLayerCpbOperationFlag` is set equal to 0.
 - Otherwise, `MultiLayerCpbOperationFlag` is set equal to 1.
7. If `sub_pic_hrd_params_present_flag` in the selected `hrd_parameters()` syntax structure is equal to 1, the CPB is scheduled to operate either at the partition unit level (in which case the variable `SubPicHrdFlag` is set equal to 0) or at the sub-partition level (in which case the variable `SubPicHrdFlag` is set equal to 1). Otherwise, `SubPicHrdFlag` is set equal to 0 and the CPB is scheduled to operate at the partition unit level.
 8. For each access unit in `TargetBitstreamPartition` starting from access unit 0, the buffering period SEI message (present in a bitstream partition nesting SEI message in `BitstreamToDecode` or available through external means not specified in this Specification) that is associated with the access unit and applies to `TargetOp`, `TargetPartitioningScheme` and `TargetBitstreamPartition` is selected, the picture timing SEI message (present in a bitstream partition nesting SEI message in `BitstreamToDecode` or available through external means not specified in this Specification) that is associated with the access unit and applies to `TargetOp`, `TargetPartitioningScheme` and `TargetBitstreamPartition` is selected, and when `SubPicHrdFlag` is equal to 1 and `sub_pic_cpb_params_in_pic_timing_sei_flag` is equal to 0, the decoding unit information SEI messages (present in bitstream partition nesting SEI messages in `BitstreamToDecode` or available through external means not specified in this Specification) that are associated with decoding units in the access unit and apply to `TargetOp`, `TargetPartitioningScheme`, and `TargetBitstreamPartition` are selected.
 9. A value of `SchedSelIdx` for `TargetBitstreamPartition` is set equal to `bsp_sched_idx[TargetOlsIdx][TargetPsIdx][HighestTid][SchedSelCombIdx][j]`, where `j` is the index of the bitstream partition index of `TargetBitstreamPartition`.
 10. The variable `initialAltParamSelectionFlag` is derived as follows:
 - If all of the following conditions are true, `initialAltParamSelectionFlag` is set equal to 1:
 - The coded picture with `nuh_layer_id` equal to `SmallestLayerId` in access unit 0 has `nal_unit_type` equal to `CRA_NUT` or `BLA_W_LP`.
 - `MultiLayerCpbOperationFlag` is equal to 0.
 - `irap_cpb_params_present_flag` in the selected buffering period SEI message is equal to 1.
 - Otherwise, if all of the following conditions are true, `initialAltParamSelectionFlag` is set equal to 1:
 - The coded picture with `nuh_layer_id` equal to `SmallestLayerId` in access unit 0 is an IRAP picture.
 - `MultiLayerCpbOperationFlag` is equal to 1.
 - `irap_cpb_params_present_flag` in the selected buffering period SEI message is equal to 1.
 - Otherwise, `initialAltParamSelectionFlag` is set equal to 0.
 11. When `initialAltParamSelectionFlag` is equal to 1, the following applies:
 - The variable `skippedPictureList` is set to consist of the CL-RAS pictures and the RASL pictures associated with the IRAP pictures with `nuh_layer_id` equal to `nuhLayerId` for which `LayerInitializedFlag[nuhLayerId]` is equal to 0 at the start of decoding the IRAP picture and for which `nuhLayerId` is among `TargetDecLayerIdList`.

- Either of the following applies for selection of the initial CPB removal delay and delay offset:
 - If `NalHrdModeFlag` is equal to 1, the default initial CPB removal delay and delay offset represented by `nal_initial_cpb_removal_delay[SchedSelIdx]` and `nal_initial_cpb_removal_offset[SchedSelIdx]`, respectively, in the selected buffering period SEI message are selected. Otherwise, the default initial CPB removal delay and delay offset represented by `vcl_initial_cpb_removal_delay[SchedSelIdx]` and `vcl_initial_cpb_removal_offset[SchedSelIdx]`, respectively, in the selected buffering period SEI message are selected. The variable `DefaultInitCpbParamsFlag` is set equal to 1.
 - If `NalHrdModeFlag` is equal to 0, the alternative initial CPB removal delay and delay offset represented by `nal_initial_alt_cpb_removal_delay[SchedSelIdx]` and `nal_initial_alt_cpb_removal_offset[SchedSelIdx]`, respectively, in the selected buffering period SEI message are selected. Otherwise, the alternative initial CPB removal delay and delay offset represented by `vcl_initial_alt_cpb_removal_delay[SchedSelIdx]` and `vcl_initial_alt_cpb_removal_offset[SchedSelIdx]`, respectively, in the selected buffering period SEI message are selected. The variable `DefaultInitCpbParamsFlag` is set equal to 0 and all the pictures in `skippedPictureList` are discarded from `BitstreamToDecode` and the remaining bitstream is assigned to `BitstreamToDecode`.

Each conformance test consists of a combination of one option in each of the above steps. When there is more than one option for a step, for any particular conformance test only one option is chosen. All possible combinations of all the steps form the entire set of conformance tests.

When `BitstreamToDecode` is a Type II bitstream, the following applies:

- If the `sub_layer_hrd_parameters(HighestTid)` syntax structure that immediately follows the condition "`if(vcl_hrd_parameters_present_flag)`" is selected, the test is conducted at the Type I conformance point and only VCL and filler data NAL units are counted for the input bit rate and CPB storage.
- Otherwise (the `sub_layer_hrd_parameters(HighestTid)` syntax structure that immediately follows the condition "`if(nal_hrd_parameters_present_flag)`" is selected), the test is conducted at the Type II conformance point, and all bytes of the Type II bitstream, which may be a NAL unit stream or a byte stream, are counted for the input bit rate and CPB storage.

NOTE 1 – NAL HRD parameters established by a value of `SchedSelIdx` for the Type II conformance point are sufficient to also establish VCL HRD conformance for the Type I conformance point for the same values of `InitCpbRemovalDelay[SchedSelIdx]`, `BitRate[SchedSelIdx]` and `CpbSize[SchedSelIdx]` for the VBR case (`cbr_flag[SchedSelIdx]` equal to 0). This is because the data flow into the Type I conformance point is a subset of the data flow into the Type II conformance point and because, for the VBR case, the CPB is allowed to become empty and stay empty until the time a next picture is scheduled to begin to arrive. For example, when decoding a CVS conforming to one or more of the profiles specified in Annex G using the decoding process specified in clauses G.2 through G.10, when NAL HRD parameters are provided for the Type II conformance point that not only fall within the bounds set for NAL HRD parameters for profile conformance in item f) of clause G.11.2.2 but also fall within the bounds set for VCL HRD parameters for profile conformance in item e) of clause G.11.2.2, conformance of the VCL HRD for the Type I conformance point is also assured to fall within the bounds of item e) of clause G.11.2.2.

All VPSs, SPSs and PPSs referred to in the VCL NAL units, and the corresponding buffering period, picture timing and decoding unit information SEI messages shall be conveyed to the HRD, in a timely manner, either in the bitstream (by non-VCL NAL units), or by other means not specified in this Specification.

In Annexes C, D and E, the specification for "presence" of non-VCL NAL units that contain VPSs, SPSs, PPSs, buffering period SEI messages, picture timing SEI messages or decoding unit information SEI messages is also satisfied when those NAL units (or just some of them) are conveyed to decoders (or to the HRD) by other means not specified in this Specification. For the purpose of counting bits, only the appropriate bits that are actually present in the bitstream are counted.

NOTE 2 – As an example, synchronization of such a non-VCL NAL unit, conveyed by means other than presence in the bitstream, with the NAL units that are present in the bitstream, can be achieved by indicating two points in the bitstream, between which the non-VCL NAL unit would have been present in the bitstream, had the encoder decided to convey it in the bitstream.

When the content of such a non-VCL NAL unit is conveyed for the application by some means other than presence within the bitstream, the representation of the content of the non-VCL NAL unit is not required to use the same syntax as specified in this Specification.

NOTE 3 – When HRD information is contained within the bitstream, it is possible to verify the conformance of a bitstream to the requirements of this clause based solely on information contained in the bitstream. When the HRD information is not present in the bitstream, as is the case for all "stand-alone" Type I bitstreams, conformance can only be verified when the HRD data are supplied by some other means not specified in this Specification.

For the bitstream-partition-specific CPB operation as specified in this annex, the HRD contains a bitstream demultiplexer (optionally present), two or more bitstream partition buffers (BPB), two or more instantaneous decoding processes, a decoded picture buffer (DPB) that contains a sub-DPB for each layer, and output cropping as shown in Figure F.1.

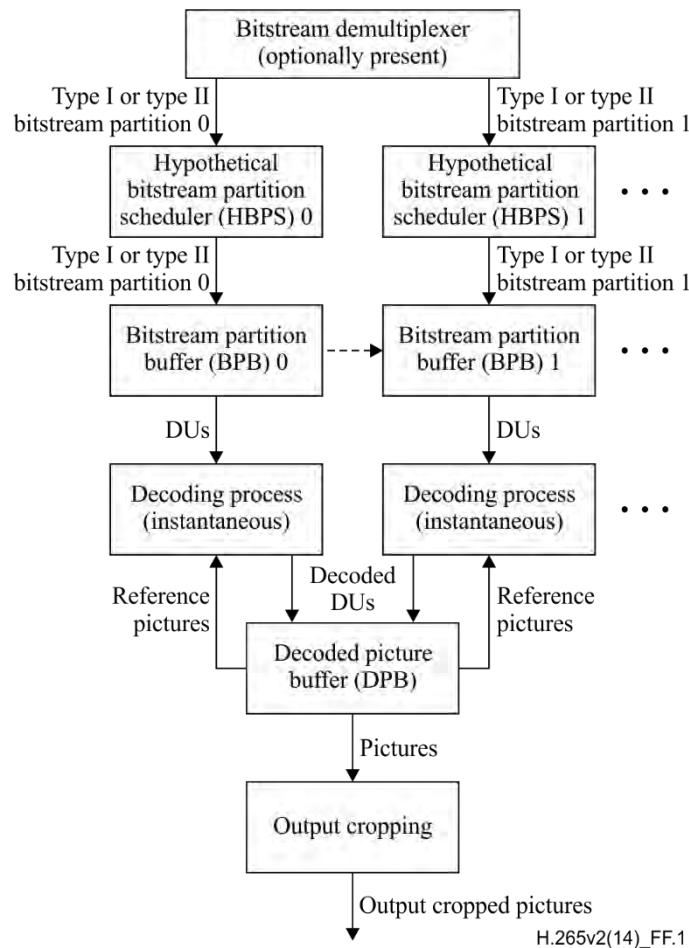

Figure F.1 – Bitstream-partition-specific HRD buffer model

For each bitstream conformance test, the size of BPB (or CPB) $CpbSize[SchedSelIdx]$ is $BpbSize[TargetOlsIdx][TargetPsIdx][HighestTid][SchedSelCombIdx][j]$, and the $BitRate[SchedSelIdx]$ is $BpBitRate[TargetOlsIdx][TargetPsIdx][HighestTid][SchedSelCombIdx][j]$, where j is the bitstream partition index of $TargetBitstreamPartition$, and $SchedSelIdx$ and the HRD parameters are specified above in this clause. The sub-DPB size of the sub-DPB for a layer with nuh_layer_id equal to $currLayerId$ is $max_vps_dec_pic_buffering_minus1[TargetOlsIdx][layerIdx][HighestTid] + 1$, where $layerIdx$ is equal to the value such that $LayerSetLayerIdList[TargetDecLayerSetIdx][layerIdx]$ is equal to $currLayerId$.

If $SubPicHrdFlag$ is equal to 0, the HRD operates at partition unit level and each decoding unit is a partition unit. Otherwise the HRD operates at sub-partition level and each decoding unit is a subset of a partition unit.

NOTE 4 – If the HRD operates at partition unit level, each time when some bits are removed from the CPB, a decoding unit that is an entire partition unit is removed from the CPB. Otherwise (the HRD operates at sub-partition level), each time when some bits are removed from the CPB, a decoding unit that is a subset of a partition unit is removed from the CPB. Regardless of whether the HRD operates at partition unit level or sub-partition level, each time when some picture is output from the DPB, an entire decoded picture is output from the DPB, though the picture output time is derived based on the differently derived CPB removal times and the differently signalled DPB output delays.

The following is specified for expressing the constraints in this annex:

- Each access unit is referred to as access unit n , where the number n identifies the particular access unit. Access unit 0 is selected per step 6 above. The value of n is incremented by 1 for each subsequent access unit in decoding order.
- Each decoding unit is referred to as decoding unit m , where the number m identifies the particular decoding unit. The first decoding unit in decoding order in access unit 0 is referred to as decoding unit 0. The value of m is incremented by 1 for each subsequent decoding unit in decoding order.

NOTE 5 – The numbering of decoding units is relative to the first decoding unit in access unit 0.

- Picture n refers to a particular coded or decoded picture of access unit n .

The HRD operates as follows:

- The HRD is initialized at decoding unit 0, with the CPB, each sub-DPB of the DPB and each BPB being set to be empty (the sub-DPB fullness for each sub-DPB is set equal to 0).
NOTE 6 – After initialization, the HRD is not initialized again by subsequent buffering period SEI messages.
- Data associated with decoding units that flow into the BPB according to a specified arrival schedule are delivered by an HBPS.
- Each bitstream partition with index j is processed as specified in clause F.13.2 with the HSS replaced by the HBPS and with SchedSelIdx equal to $\text{bsp_sched_idx}[\text{TargetOlsIdx}][\text{TargetPsIdx}][\text{HighestTid}][\text{SchedSelCombIdx}][j]$.
- The data associated with each decoding unit are removed and decoded instantaneously by the instantaneous decoding process at the CPB removal time of the decoding unit.
- Each decoded picture is placed in the DPB.
- A decoded picture is removed from the DPB when it becomes no longer needed for inter prediction reference and no longer needed for output.

For each bitstream conformance test, the operation of the CPB and the BPB is specified in clause F.13.2, the instantaneous decoder operation is specified in clauses 2 through 10, clauses F.2 through F.10, and either clauses G.2 through G.10 or clauses H.2 through H.10, the operation of the DPB is specified in clause F.13.3, and the output cropping is specified in clauses F.13.3.3 and F.13.5.2.2.

HSS, HBPS and HRD information concerning the number of enumerated delivery schedules and their associated bit rates and buffer sizes is specified in clauses E.2.2, E.2.3, F.7.3.2.1.6 and F.7.4.3.1.6. The HRD is initialized as specified by the buffering period SEI message specified in clauses D.2.2 and D.3.2. The removal timing of decoding units from the CPB and output timing of decoded pictures from the DPB is specified using information in picture timing SEI messages (specified in clauses D.2.3 and D.3.3) or in decoding unit information SEI messages (specified in clauses D.2.22 and D.3.22). All timing information relating to a specific decoding unit shall arrive prior to the CPB removal time of the decoding unit.

The requirements for bitstream conformance are specified in clause F.13.4 and the HRD is used to check conformance of bitstreams as specified above in this clause and to check conformance of decoders as specified in clause F.13.5.

F.13.2 Operation of bitstream partition buffer

F.13.2.1 General

The specifications in this clause apply independently to each set of bitstream partition buffer (BPB) parameters that is present and to both the Type I and Type II conformance points and the set of BPB parameters is selected as specified in clause F.13.1. In clause F.13.2 and its subclauses, CPB is understood to be BPB and access unit is understood to be partition unit.

F.13.2.2 Timing of decoding unit arrival

The variable altParamSelectionFlag is derived as follows:

- If all of the following conditions are true, altParamSelectionFlag is set equal to 1:
 - The current picture is a BLA picture that has nal_unit_type equal to BLA_W_LP and nuh_layer_id equal to SmallestLayerId or is a CRA picture that has nuh_layer_id equal to SmallestLayerId.
 - MultiLayerCpbOperationFlag is equal to 0.
- Otherwise, if all of the following conditions are true, altParamSelectionFlag is set equal to 1:
 - The current picture is an IRAP picture with nuh_layer_id equal to SmallestLayerId and with NoClrasOutputFlag equal to 1.
 - MultiLayerCpbOperationFlag is equal to 1.
- Otherwise, altParamSelectionFlag is set equal to 0.

When altParamSelectionFlag is equal to 1, the following applies:

- If some external means not specified in this Specification is available to set the variable UseAltCpbParamsFlag to a value, UseAltCpbParamsFlag is set equal to the value provided by the external means.
- Otherwise, UseAltCpbParamsFlag is set equal to the value of use_alt_cpb_params_flag of the buffering period SEI message selected as specified in clause F.13.1.

If SubPicHrdFlag is equal to 0, the variable subPicParamsFlag is set equal to 0 and the process specified in the remainder of this clause is invoked with a decoding unit being considered as an access unit, for derivation of the initial and final CPB arrival times for access unit n.

Otherwise (SubPicHrdFlag is equal to 1), the process specified in the remainder of this clause is first invoked with the variable subPicParamsFlag set equal to 0 and a decoding unit being considered as an access unit, for derivation of the initial and final CPB arrival times for access unit n, and then invoked with subPicParamsFlag set equal to 1 and a decoding unit being considered as a subset of an access unit, for derivation of the initial and final CPB arrival times for the decoding units in access unit n.

The variables InitCpbRemovalDelay[SchedSelIdx] and InitCpbRemovalDelayOffset[SchedSelIdx] are derived as follows:

- If one or more of the following conditions are true, InitCpbRemovalDelay[SchedSelIdx] and InitCpbRemovalDelayOffset[SchedSelIdx] are set equal to the values of the buffering period SEI message syntax elements nal_initial_alt_cpb_removal_delay[SchedSelIdx] and nal_initial_alt_cpb_removal_offset[SchedSelIdx], respectively, when NalHrdModeFlag is equal to 1, or vcl_initial_alt_cpb_removal_delay[SchedSelIdx] and vcl_initial_alt_cpb_removal_offset[SchedSelIdx], respectively, when NalHrdModeFlag is equal to 0, where the buffering period SEI message syntax elements are selected as specified in clause F.13.1:
 - Access unit 0 includes a BLA picture with nuh_layer_id equal to SmallestLayerId and nal_unit_type equal to BLA_W_RADL or BLA_N_LP, MultiLayerCpbOperationFlag is equal to 0 and the value of irap_cpb_params_present_flag of the buffering period SEI message is equal to 1.
 - Access unit 0 includes a BLA picture with nuh_layer_id equal to SmallestLayerId and nal_unit_type equal to BLA_W_LP or includes a CRA picture with nuh_layer_id equal to SmallestLayerId, MultiLayerCpbOperationFlag is equal to 0, and the value of irap_cpb_params_present_flag of the buffering period SEI message is equal to 1 and one or more of the following conditions are true:
 - UseAltCpbParamsFlag for access unit 0 is equal to 1.
 - DefaultInitCpbParamsFlag is equal to 0.
 - Access unit 0 includes an IRAP picture with nuh_layer_id equal to SmallestLayerId, MultiLayerCpbOperationFlag is equal to 1 and the value of irap_cpb_params_present_flag of the buffering period SEI message is equal to 1 and one or more of the following conditions are true:
 - UseAltCpbParamsFlag for access unit 0 is equal to 1.
 - DefaultInitCpbParamsFlag is equal to 0.
 - The value of subPicParamsFlag is equal to 1.
- Otherwise, InitCpbRemovalDelay[SchedSelIdx] and InitCpbRemovalDelayOffset[SchedSelIdx] are set equal to the values of the buffering period SEI message syntax elements nal_initial_cpb_removal_delay[SchedSelIdx] and nal_initial_cpb_removal_offset[SchedSelIdx], respectively, when NalHrdModeFlag is equal to 1, or vcl_initial_cpb_removal_delay[SchedSelIdx] and vcl_initial_cpb_removal_offset[SchedSelIdx], respectively, when NalHrdModeFlag is equal to 0, where the buffering period SEI message syntax elements are selected as specified in clause F.13.1.

The time at which the first bit of decoding unit m begins to enter the CPB is referred to as the initial arrival time initArrivalTime[m].

Decoding units are indexed in decoding order within the bitstream.

The initial arrival time of decoding unit m is derived as follows:

- If the decoding unit is decoding unit 0 (i.e., when m is equal to 0) and the decoding unit belongs to the base bitstream partition, initArrivalTime[0] is set equal to 0.
- Otherwise, if the decoding unit is decoding unit 0 and the decoding unit does not belong to the base bitstream partition, initArrivalTime[0] is obtained from the bitstream partition initial arrival time SEI message that applies to TargetOp, TargetPartitioningScheme, and TargetBitstreamPartition and is associated with the access unit containing decoding unit 0. The applicable bitstream partition initial arrival time SEI message is either included in a bitstream partition nesting SEI message in an SEI NAL unit in the access unit containing decoding unit 0 in BitstreamToDecode or available through external means not specified in this Specification. If NalHrdModeFlag is equal to 0, initArrivalTime[0] is set equal to vcl_initial_arrival_delay[SchedSelIdx] in the applicable bitstream partition initial arrival time SEI message. Otherwise (NalHrdModeFlag is equal to 1), initArrivalTime[0] is set equal to nal_initial_arrival_delay[SchedSelIdx] in the applicable bitstream partition initial arrival time SEI message.
- Otherwise, the following applies:

- If $cbr_flag[SchedSelIdx]$ is equal to 1, the initial arrival time for decoding unit m is equal to the final arrival time (which is derived below) of decoding unit $m - 1$, i.e.,

$$\begin{aligned} & \text{if(!subPicParamsFlag)} \\ & \quad \text{initArrivalTime}[m] = \text{AuFinalArrivalTime}[m - 1] \\ & \text{else} \\ & \quad \text{initArrivalTime}[m] = \text{DuFinalArrivalTime}[m - 1] \end{aligned} \quad (\text{F-69})$$

- Otherwise ($cbr_flag[SchedSelIdx]$ is equal to 0), the initial arrival time for decoding unit m is derived as follows:

$$\begin{aligned} & \text{if(!subPicParamsFlag)} \\ & \quad \text{initArrivalTime}[m] = \text{Max}(\text{AuFinalArrivalTime}[m - 1], \text{initArrivalEarliestTime}[m]) \\ & \quad (\text{F-70}) \\ & \text{else} \\ & \quad \text{initArrivalTime}[m] = \text{Max}(\text{DuFinalArrivalTime}[m - 1], \text{initArrivalEarliestTime}[m]) \end{aligned}$$

where $\text{initArrivalEarliestTime}[m]$ is derived as follows:

- The variable $\text{tmpNominalRemovalTime}$ is derived as follows:

$$\begin{aligned} & \text{if(!subPicParamsFlag)} \\ & \quad \text{tmpNominalRemovalTime} = \text{AuNominalRemovalTime}[m] \\ & \text{else} \\ & \quad \text{tmpNominalRemovalTime} = \text{DuNominalRemovalTime}[m] \end{aligned} \quad (\text{F-71})$$

where $\text{AuNominalRemovalTime}[m]$ and $\text{DuNominalRemovalTime}[m]$ are the nominal CPB removal time of access unit m and decoding unit m , respectively, as specified in clause F.13.2.3.

- If decoding unit m is not the first decoding unit of a subsequent buffering period, $\text{initArrivalEarliestTime}[m]$ is derived as follows:

$$\begin{aligned} \text{initArrivalEarliestTime}[m] = & \text{tmpNominalRemovalTime} - \\ & (\text{InitCpbRemovalDelay}[SchedSelIdx] \\ & + \text{InitCpbRemovalDelayOffset}[SchedSelIdx]) \div 90\,000 \end{aligned} \quad (\text{F-72})$$

- Otherwise (decoding unit m is the first decoding unit of a subsequent buffering period), $\text{initArrivalEarliestTime}[m]$ is derived as follows:

$$\begin{aligned} \text{initArrivalEarliestTime}[m] = & \text{tmpNominalRemovalTime} - \\ & (\text{InitCpbRemovalDelay}[SchedSelIdx] \div 90\,000) \end{aligned} \quad (\text{F-73})$$

The final arrival time for decoding unit m is derived as follows:

$$\begin{aligned} & \text{if(!subPicParamsFlag)} \\ & \quad \text{AuFinalArrivalTime}[m] = \text{initArrivalTime}[m] + \text{sizeInbits}[m] \div \text{BitRate}[SchedSelIdx] \\ & \quad (\text{F-74}) \\ & \text{else} \\ & \quad \text{DuFinalArrivalTime}[m] = \text{initArrivalTime}[m] + \text{sizeInbits}[m] \div \text{BitRate}[SchedSelIdx] \end{aligned}$$

where $\text{sizeInbits}[m]$ is the size in bits of decoding unit m , counting the bits of the VCL NAL units and the filler data NAL units for the Type I conformance point or all bits of the Type II bitstream for the Type II conformance point.

The values of $SchedSelIdx$, $\text{BitRate}[SchedSelIdx]$ and $\text{CpbSize}[SchedSelIdx]$ are constrained as follows:

- If the lists of delivery schedules, including the HRD parameters associated with the individual delivery schedules, for the access unit containing decoding unit m and the previous access unit differ, the HSS selects a value $SchedCombIdx1$ in the range of 0 to $\text{num_bsp_schedules_minus1}[\text{TargetOlsIdx}][\text{TargetPsIdx}][\text{HighestTid}]$, inclusive, and sets $SchedSelIdx1$ for $\text{TargetBitstreamPartition}$ to be equal to $\text{bsp_sched_idx}[\text{TargetOlsIdx}][\text{TargetPsIdx}][\text{HighestTid}][\text{SchedSelCombIdx}][j]$, where j is the index of the bitstream partition index of $\text{TargetBitstreamPartition}$, for the access unit containing decoding unit m that results in a $\text{BitRate}[SchedSelIdx1]$ or $\text{CpbSize}[SchedSelIdx1]$ for the access unit containing decoding unit m . The value of $\text{BitRate}[SchedSelIdx1]$ or $\text{CpbSize}[SchedSelIdx1]$ may differ from the value of $\text{BitRate}[SchedSelIdx0]$ or $\text{CpbSize}[SchedSelIdx0]$ for the value $SchedSelIdx0$ of $SchedSelIdx$ that was in use for the previous access unit.
- Otherwise, the HSS continues to operate with the previous values of $SchedSelIdx$, $\text{BitRate}[SchedSelIdx]$ and $\text{CpbSize}[SchedSelIdx]$.

When the HSS selects values of `BitRate[SchedSelIdx]` or `CpbSize[SchedSelIdx]` that differ from those of the previous access unit, the following applies:

- The variable `BitRate[SchedSelIdx]` comes into effect at the initial CPB arrival time of the current access unit.
- The variable `CpbSize[SchedSelIdx]` comes into effect as follows:
 - If the new value of `CpbSize[SchedSelIdx]` is greater than the old CPB size, it comes into effect at the initial CPB arrival time of the current access unit.
 - Otherwise, the new value of `CpbSize[SchedSelIdx]` comes into effect at the CPB removal time of the current access unit.

F.13.2.3 Timing of decoding unit removal and decoding of decoding unit

The variables `InitCpbRemovalDelay[SchedSelIdx]`, `InitCpbRemovalDelayOffset[SchedSelIdx]`, `CpbDelayOffset` and `DpbDelayOffset` are derived as follows:

- If one or more of the following conditions are true, `CpbDelayOffset` is set equal to the value of the buffering period SEI message syntax element `cpb_delay_offset`, `DpbDelayOffset` is set equal to the value of the buffering period SEI message syntax element `dpb_delay_offset` and `InitCpbRemovalDelay[SchedSelIdx]` and `InitCpbRemovalDelayOffset[SchedSelIdx]` are set equal to the values of the buffering period SEI message syntax elements `nal_initial_alt_cpb_removal_delay[SchedSelIdx]` and `nal_initial_alt_cpb_removal_offset[SchedSelIdx]`, respectively, when `NalHrdModeFlag` is equal to 1, or `vcl_initial_alt_cpb_removal_delay[SchedSelIdx]` and `vcl_initial_alt_cpb_removal_offset[SchedSelIdx]`, respectively, when `NalHrdModeFlag` is equal to 0, where the buffering period SEI message containing the syntax elements is selected as specified in clause F.13.1:
 - Access unit 0 includes a BLA picture with `nuh_layer_id` equal to `SmallestLayerId` and `nal_unit_type` equal to `BLA_W_RADL` or `BLA_N_LP`, `MultiLayerCpbOperationFlag` is equal to 0 and the value of `irap_cpb_params_present_flag` of the buffering period SEI message is equal to 1.
 - Access unit 0 includes a BLA picture with `nuh_layer_id` equal to `SmallestLayerId` and `nal_unit_type` equal to `BLA_W_LP` or includes a CRA picture with `nuh_layer_id` equal to `SmallestLayerId`, `MultiLayerCpbOperationFlag` is equal to 0 and the value of `irap_cpb_params_present_flag` of the buffering period SEI message is equal to 1, and one or more of the following conditions are true:
 - `UseAltCpbParamsFlag` for access unit 0 is equal to 1.
 - `DefaultInitCpbParamsFlag` is equal to 0.
 - Access unit 0 includes an IRAP picture with `nuh_layer_id` equal to `SmallestLayerId`, `MultiLayerCpbOperationFlag` is equal to 1 and the value of `irap_cpb_params_present_flag` of the buffering period SEI message is equal to 1 and one or more of the following conditions are true:
 - `UseAltCpbParamsFlag` for access unit 0 is equal to 1.
 - `DefaultInitCpbParamsFlag` is equal to 0.
- Otherwise, `InitCpbRemovalDelay[SchedSelIdx]` and `InitCpbRemovalDelayOffset[SchedSelIdx]` are set equal to the values of the buffering period SEI message syntax elements `nal_initial_cpb_removal_delay[SchedSelIdx]` and `nal_initial_cpb_removal_offset[SchedSelIdx]`, respectively, when `NalHrdModeFlag` is equal to 1, or `vcl_initial_cpb_removal_delay[SchedSelIdx]` and `vcl_initial_cpb_removal_offset[SchedSelIdx]`, respectively, when `NalHrdModeFlag` is equal to 0, where the buffering period SEI message containing the syntax elements is selected as specified in clause F.13.1, `CpbDelayOffset` and `DpbDelayOffset` are both set equal to 0.

The nominal removal time of the access unit `n` from the CPB is specified as follows:

- If access unit `n` is the access unit with `n` equal to 0 (the access unit that initializes the HRD), the nominal removal time of the access unit from the CPB is specified by:

$$AuNominalRemovalTime[0] = InitCpbRemovalDelay[SchedSelIdx] \div 90\,000 \quad (F-75)$$

- Otherwise, the following applies:
 - When access unit `n` is the first access unit of a buffering period that does not initialize the HRD, the following applies:

The nominal removal time of the access unit `n` from the CPB is specified by:

```

if( !concatenationFlag ) {
    baseTime = AuNominalRemovalTime[ firstPicInPrevBuffPeriod ]
    tmpCpbRemovalDelay = AuCpbRemovalDelayVal

```

```

} else {
    baseTime = AuNominalRemovalTime[ prevNonDiscardablePic ]
    tmpCpbRemovalDelay =
        Max( ( auCpbRemovalDelayDeltaMinus1 + 1 ),
            Ceil( ( InitCpbRemovalDelay[ SchedSelIdx ] ÷ 90 000 +
                AuFinalArrivalTime[ n - 1 ] - AuNominalRemovalTime[ n - 1 ] ) ÷ ClockTick ) )
}
AuNominalRemovalTime[ n ] = baseTime + ClockTick * ( tmpCpbRemovalDelay -
    CpbDelayOffset )

```

(F-76)

where $AuNominalRemovalTime[firstPicInPrevBuffPeriod]$ is the nominal removal time of the first access unit of the previous buffering period, $AuNominalRemovalTime[prevNonDiscardablePic]$ is the nominal removal time of the preceding access unit in decoding order, each picture of which is with TemporalId equal to 0 that is not a RASL, RADL or SLNR picture, $AuCpbRemovalDelayVal$ is the value of $AuCpbRemovalDelayVal$ derived according to $au_cpb_removal_delay_minus1$ in the picture timing SEI message, selected as specified in clause F.13.1, associated with access unit n , and concatenationFlag and $auCpbRemovalDelayDeltaMinus1$ are the values of the syntax elements concatenation_flag and $au_cpb_removal_delay_delta_minus1$, respectively, in the buffering period SEI message, selected as specified in clause F.13.1, associated with access unit n .

After the derivation of the nominal CPB removal time and before the derivation of the DPB output time of access unit n , the values of CpbDelayOffset and DpbDelayOffset are updated as follows:

- If one or more of the following conditions are true, CpbDelayOffset is set equal to the value of the buffering period SEI message syntax element cpb_delay_offset and DpbDelayOffset is set equal to the value of the buffering period SEI message syntax element dpb_delay_offset , where the buffering period SEI message containing the syntax elements is selected as specified in clause F.13.1:
 - Access unit n includes a BLA picture with nuh_layer_id equal to SmallestLayerId and nal_unit_type equal to BLA_W_RADL or BLA_N_LP, MultiLayerCpbOperationFlag is equal to 0 and the value of $irap_cpb_params_present_flag$ of the buffering period SEI message is equal to 1.
 - Access unit n includes a BLA picture with nuh_layer_id equal to SmallestLayerId and nal_unit_type equal to BLA_W_LP or includes a CRA picture with nuh_layer_id equal to SmallestLayerId, MultiLayerCpbOperationFlag is equal to 0, the value of $irap_cpb_params_present_flag$ of the buffering period SEI message is equal to 1 and UseAltCpbParamsFlag for access unit n is equal to 1.
 - Access unit n includes an IRAP picture with nuh_layer_id equal to SmallestLayerId, MultiLayerCpbOperationFlag is equal to 1, the value of $irap_cpb_params_present_flag$ of the buffering period SEI message is equal to 1 and UseAltCpbParamsFlag for access unit n is equal to 1.
- Otherwise, CpbDelayOffset and DpbDelayOffset are both set equal to 0.
- When access unit n is not the first access unit of a buffering period, the nominal removal time of the access unit n from the CPB is specified by:

$$AuNominalRemovalTime[n] = AuNominalRemovalTime[firstPicInCurrBuffPeriod] + ClockTick * (AuCpbRemovalDelayVal - CpbDelayOffset) \quad (F-77)$$

where $AuNominalRemovalTime[firstPicInCurrBuffPeriod]$ is the nominal removal time of the first access unit of the current buffering period, and $AuCpbRemovalDelayVal$ is the value of $AuCpbRemovalDelayVal$ derived according to $au_cpb_removal_delay_minus1$ in the picture timing SEI message, selected as specified in clause F.13.1, associated with access unit n .

When SubPicHrdFlag is equal to 1, the following applies:

- The variable $duCpbRemovalDelayInc$ is derived as follows:
 - If $sub_pic_cpb_params_in_pic_timing_sei_flag$ is equal to 0, $duCpbRemovalDelayInc$ is set equal to the value of $du_spt_cpb_removal_delay_increment$ in the decoding unit information SEI message, selected as specified in clause F.13.1, associated with decoding unit m .
 - Otherwise, if $du_common_cpb_removal_delay_flag$ is equal to 0, $duCpbRemovalDelayInc$ is set equal to the value of $du_cpb_removal_delay_increment_minus1[i] + 1$ for decoding unit m in the picture timing SEI message, selected as specified in clause F.13.1, associated with access unit n , where the value of i is 0 for the first $num_nalus_in_du_minus1[0] + 1$ consecutive NAL units in the access unit that contains decoding unit m , 1 for the subsequent $num_nalus_in_du_minus1[1] + 1$ NAL units in the same access unit, 2 for the subsequent $num_nalus_in_du_minus1[2] + 1$ NAL units in the same access unit, etc.

- Otherwise, `duCpbRemovalDelayInc` is set equal to the value of `du_common_cpb_removal_delay_increment_minus1 + 1` in the picture timing SEI message, selected as specified in clause F.13.1, associated with access unit `n`.
- The nominal removal time of decoding unit `m` from the CPB is specified as follows, where `AuNominalRemovalTime[n]` is the nominal removal time of access unit `n`:
 - If decoding unit `m` is the last decoding unit in access unit `n`, the nominal removal time of decoding unit `m` `DuNominalRemovalTime[m]` is set equal to `AuNominalRemovalTime[n]`.
 - Otherwise (decoding unit `m` is not the last decoding unit in access unit `n`), the nominal removal time of decoding unit `m` `DuNominalRemovalTime[m]` is derived as follows:

$$\begin{aligned}
 &\text{if(sub_pic_cpb_params_in_pic_timing_sei_flag)} \\
 &\quad \text{DuNominalRemovalTime[m]} = \text{DuNominalRemovalTime[m + 1]} - \\
 &\quad \text{ClockSubTick} * \text{duCpbRemovalDelayInc} \\
 &\text{else} \\
 &\quad \text{DuNominalRemovalTime[m]} = \text{AuNominalRemovalTime[n]} - \\
 &\quad \text{ClockSubTick} * \text{duCpbRemovalDelayInc}
 \end{aligned}
 \tag{F-78}$$

If `SubPicHrdFlag` is equal to 0, the removal time of access unit `n` from the CPB is specified as follows, where `AuFinalArrivalTime[n]` and `AuNominalRemovalTime[n]` are the final CPB arrival time and nominal CPB removal time, respectively, of access unit `n`:

$$\begin{aligned}
 &\text{if(!low_delay_hrd_flag[HighestTid] || AuNominalRemovalTime[n] >=} \\
 &\quad \text{AuFinalArrivalTime[n]}) \\
 &\quad \text{AuCpbRemovalTime[n]} = \text{AuNominalRemovalTime[n]} \\
 &\text{else} \\
 &\quad \text{AuCpbRemovalTime[n]} = \text{AuNominalRemovalTime[n]} + \text{ClockTick} * \\
 &\quad \text{Ceil((AuFinalArrivalTime[n] - AuNominalRemovalTime[n]) } \div \text{ClockTick})
 \end{aligned}
 \tag{F-79}$$

NOTE 1 – When `low_delay_hrd_flag[HighestTid]` is equal to 1 and `AuNominalRemovalTime[n]` is less than `AuFinalArrivalTime[n]`, the size of access unit `n` is so large that it prevents removal at the nominal removal time.

Otherwise (`SubPicHrdFlag` is equal to 1), the removal time of decoding unit `m` from the CPB is specified as follows:

$$\begin{aligned}
 &\text{– The following applies:} \\
 &\quad \text{if(!low_delay_hrd_flag[HighestTid] || DuNominalRemovalTime[m] >=} \\
 &\quad \quad \text{DuFinalArrivalTime[m]}) \\
 &\quad \quad \text{DuCpbRemovalTime[m]} = \text{DuNominalRemovalTime[m]} \\
 &\quad \text{else} \\
 &\quad \quad \text{DuCpbRemovalTime[m]} = \text{DuFinalArrivalTime[m]}
 \end{aligned}
 \tag{F-80}$$

NOTE 2 – When `low_delay_hrd_flag[HighestTid]` is equal to 1 and `DuNominalRemovalTime[m]` is less than `DuFinalArrivalTime[m]`, the size of decoding unit `m` is so large that it prevents removal at the nominal removal time.

- When `cbr_flag[SchedSelIdx]` is equal to 0, the following applies:
 - Let `refDuCpbRemovalTime` be equal to the CPB removal time of the previous DU preceding the current DU in decoding order (regardless of the bitstream partitions to which the previous DU and the current DU belong).
 - The variable `DuCpbRemovalTime[m]` is modified as follows:

$$\text{DuCpbRemovalTime[m]} = \text{Max(DuCpbRemovalTime[m], refDuCpbRemovalTime)}
 \tag{F-81}$$

If `SubPicHrdFlag` is equal to 0, at the CPB removal time of access unit `n`, the access unit is instantaneously decoded.

Otherwise (`SubPicHrdFlag` is equal to 1), at the CPB removal time of decoding unit `m`, the decoding unit is instantaneously decoded, and when decoding unit `m` is the last decoding unit of access unit `n`, the following applies:

- Access unit `n` is considered as decoded.
- The final CPB arrival time of access unit `n`, i.e., `AuFinalArrivalTime[n]`, is set equal to the final CPB arrival time of the last decoding unit in access unit `n`, i.e., `DuFinalArrivalTime[m]`.
- The nominal CPB removal time of access unit `n`, i.e., `AuNominalRemovalTime[n]`, is set equal to the nominal CPB removal time of the last decoding unit in access unit `n`, i.e., `DuNominalRemovalTime[m]`.

- The CPB removal time of access unit n , i.e., $AuCpbRemovalTime[m]$, is set equal to the CPB removal time of the last decoding unit in access unit n , i.e., $DuCpbRemovalTime[m]$.

F.13.3 Operation of decoded picture buffer

F.13.3.1 General

The specifications in this clause apply independently to each set of decoded picture buffer (DPB) parameters selected as specified in clause F.13.1.

The decoded picture buffer consists of sub-DPBs and each sub-DPB contains picture storage buffers for storage of decoded pictures of one layer. Each of the picture storage buffers of a sub-DPB may contain a decoded picture that is marked as "used for reference" or is held for future output.

The processes specified in clauses F.13.3.2, F.13.3.3, F.13.3.4 and F.13.3.5 are sequentially applied as specified below, and are applied independently for each layer, starting from the base layer, in increasing order of nuh_layer_id values of the layers in the bitstream. When these processes are applied for a particular layer, only the sub-DPB for the particular layer is affected. In the descriptions of these processes, the DPB refers to the sub-DPB for the particular layer, and the particular layer is referred to as the current layer.

NOTE – In the operation of output timing DPB, decoded pictures with $PicOutputFlag$ equal to 1 in the same access unit are output consecutively in ascending order of the nuh_layer_id values of the decoded pictures.

Let picture n and the current picture be the coded picture or decoded picture of the access unit n for a particular value of nuh_layer_id , wherein n is a non-negative integer number.

F.13.3.2 Removal of pictures from the DPB before decoding of the current picture

When the current picture is not picture 0 in the current layer, the removal of pictures in the current layer, with nuh_layer_id equal to $currLayerId$, from the DPB before decoding of the current picture, i.e., picture n , but after parsing the slice header of the first slice of the current picture, happens instantaneously at the CPB removal time of the first decoding unit of the current picture and proceeds as follows:

- The decoding process for RPS as specified in clause F.8.3.2 is invoked.
- The variable $listOfSubDpbsToEmpty$ is derived as follows:
 - If a new VPS is activated by the current access unit or the current picture is an IRAP picture with nuh_layer_id equal to $SmallestLayerId$, $NoRaslOutputFlag$ equal to 1 and $NoCllasOutputFlag$ equal to 1, $listOfSubDpbsToEmpty$ is set to include all the sub-DPBs.
 - Otherwise, if the current picture is an IRAP picture with any nuh_layer_id value $indepLayerId$ such that $NumDirectRefLayers[indepLayerId]$ is equal to 0 and $indepLayerId$ is greater than $SmallestLayerId$, and with $NoRaslOutputFlag$ equal to 1, and $LayerResetFlag$ is equal to 1, $listOfSubDpbsToEmpty$ is set equal to the sub-DPBs containing the current layer and the sub-DPBs containing the predicted layers of the current layer.
 - Otherwise, $listOfSubDpbsToEmpty$ is set equal to the sub-DPB containing the current layer.
- When the current picture is an IRAP picture with $NoRaslOutputFlag$ equal to 1 and any of the following conditions is true:
 - nuh_layer_id equal to $SmallestLayerId$,
 - nuh_layer_id of the current layer is greater than $SmallestLayerId$ and $NumDirectRefLayers[nuh_layer_id]$ is equal to 0,

the following ordered steps are applied:

1. The variable $NoOutputOfPriorPicsFlag$ is derived for the decoder under test as follows:
 - If the current picture is a CRA picture, $NoOutputOfPriorPicsFlag$ is set equal to 1 (regardless of the value of $no_output_of_prior_pics_flag$).
 - Otherwise, if the value of $pic_width_in_luma_samples$, $pic_height_in_luma_samples$, $chroma_format_idc$, $bit_depth_luma_minus8$, $bit_depth_chroma_minus8$, $separate_colour_plane_flag$ or $sps_max_dec_pic_buffering_minus1[HighestTid]$ derived from the active SPS for the current layer is different from the value of $pic_width_in_luma_samples$, $pic_height_in_luma_samples$, $chroma_format_idc$, $bit_depth_luma_minus8$, $bit_depth_chroma_minus8$, $separate_colour_plane_flag$ or $sps_max_dec_pic_buffering_minus1[HighestTid]$, respectively, derived from the SPS that was active for the current layer when decoding the preceding picture in the current layer, $NoOutputOfPriorPicsFlag$ may (but should not) be set equal to 1 by the decoder under test, regardless of the value of $no_output_of_prior_pics_flag$.

NOTE – Although setting NoOutputOfPriorPicsFlag equal to no_output_of_prior_pics_flag is preferred under these conditions, the decoder under test is allowed to set NoOutputOfPriorPicsFlag to 1 in this case.

- Otherwise, NoOutputOfPriorPicsFlag is set equal to no_output_of_prior_pics_flag.
- 2. When the value of NoOutputOfPriorPicsFlag derived for the decoder under test is equal to 1, all non-empty picture storage buffers in all the sub-DPBs contained in listOfSubDpbsToEmpty are emptied without output of the pictures they contain, and the sub-DPB fullness of each sub-DPB in listOfSubDpbsToEmpty is set equal to 0.
- When both of the following conditions are true for any pictures k in the DPB, all such pictures k in the DPB are removed from the DPB:
 - picture k is marked as "unused for reference".
 - picture k has PicOutputFlag equal to 0 or its DPB output time is less than or equal to the CPB removal time of the first decoding unit (denoted as decoding unit m) of the current picture n; i.e., DpbOutputTime[k] is less than or equal to DuCpbRemovalTime[m].
- For each picture that is removed from the DPB, the DPB fullness is decremented by one.

F.13.3.3 Picture output

The processes specified in this clause happen instantaneously at the CPB removal time of access unit n, AuCpbRemovalTime[n].

When access unit n has AuOutputFlag equal to 1, its DPB output time DpbOutputTime[n] is derived as follows, where the variable firstPicInBufferingPeriodFlag is equal to 1 if access unit n is the first access unit of a buffering period and 0 otherwise:

```

if( !SubPicHrdFlag ) {
    DpbOutputTime[ n ] = AuCpbRemovalTime[ n ] + ClockTick * picDpbOutputDelay      (F-82)
    if( firstPicInBufferingPeriodFlag )
        DpbOutputTime[ n ] -= ClockTick * DpbDelayOffset
} else
    DpbOutputTime[ n ] = AuCpbRemovalTime[ n ] + ClockSubTick * picSptDpbOutputDuDelay

```

where picDpbOutputDelay is the value of pic_dpb_output_delay in the picture timing SEI message associated with access unit n, and picSptDpbOutputDuDelay is the value of pic_spt_dpb_output_du_delay, when present, in the decoding unit information SEI messages associated with access unit n, or the value of pic_dpb_output_du_delay in the picture timing SEI message associated with access unit n when there is no decoding unit information SEI message associated with access unit n or no decoding unit information SEI message associated with access unit n has pic_spt_dpb_output_du_delay present.

NOTE – When the syntax element pic_spt_dpb_output_du_delay is not present in any decoding unit information SEI message associated with access unit n, the value is inferred to be equal to pic_dpb_output_du_delay in the picture timing SEI message associated with access unit n.

The output of the current picture contained in access unit n is specified as follows:

- If PicOutputFlag is equal to 1 and DpbOutputTime[n] is equal to AuCpbRemovalTime[n], the current picture is output.
- Otherwise, if PicOutputFlag is equal to 0, the current picture is not output, but will be stored in the DPB as specified in clause F.13.3.4.
- Otherwise (PicOutputFlag is equal to 1 and DpbOutputTime[n] is greater than AuCpbRemovalTime[n]), the current picture is output later and will be stored in the DPB (as specified in clause F.13.3.4) and is output at time DpbOutputTime[n] unless indicated not to be output by NoOutputOfPriorPicsFlag equal to 1.

When output, a picture is cropped, using the conformance cropping window specified in the active SPS for the layer containing the picture.

When access unit n is an access unit that has AuOutputFlag equal to 1 and is not the last access unit of the bitstream that has AuOutputFlag equal to 1, the value of the variable DpbOutputInterval[n] is derived as follows:

$$\text{DpbOutputInterval}[n] = \text{DpbOutputTime}[\text{nextAuInOutputOrder}] - \text{DpbOutputTime}[n] \quad (\text{F-83})$$

where nextAuInOutputOrder is the access unit that follows access unit n in output order and has AuOutputFlag equal to 1.

F.13.3.4 Current decoded picture marking and storage

The current decoded picture after the invocation of the in-loop filter process as specified in clause F.8.7 is stored in the DPB in an empty picture storage buffer, the DPB fullness is incremented by one and this picture is marked as "used for short-term reference".

When TwoVersionsOfCurrDecPicFlag is equal to 1, the current decoded picture before the invocation of the in-loop filter process as specified in clause F.8.7 is stored in the DPB in an empty picture storage buffer, the DPB fullness is incremented by one, and this picture is marked as "used for long-term reference".

NOTE – Unless more memory than required by the level limit is available for storage of decoded pictures, decoders should start storing decoded parts of the current picture into the DPB when the first slice segment is decoded and continue storing more decoded samples as the decoding process proceeds.

F.13.3.5 Removal of pictures from the DPB after decoding of the current picture

When TwoVersionsOfCurrDecPicFlag is equal to 1, immediately after decoding of the current picture, at the CPB removal time of the last decoding unit of access unit n (containing the current picture), the current decoded picture that is marked as "used for long-term reference" is removed from the DPB, and the DPB fullness is decremented by one.

F.13.4 Bitstream conformance

A bitstream of coded data conforming to this Specification shall fulfil all requirements specified in this clause.

The bitstream shall be constructed according to the syntax, semantics and constraints specified in this Specification outside of this annex.

The first access unit in a bitstream shall be an IRAP access unit.

When vps_base_layer_internal_flag is equal to 0, all the following bitstream conformance constraints apply only to coded pictures present in the bitstream and do not apply to pictures with nuh_layer_id equal to 0 which are provided by external means.

Let currPicLayerId be equal to the nuh_layer_id of the current picture.

For each current picture, let the variables maxPicOrderCnt and minPicOrderCnt be set equal to the maximum and the minimum, respectively, of the PicOrderCntVal values of the following pictures with nuh_layer_id equal to currPicLayerId:

- The current picture.
- The previous picture in decoding order that has TemporalId equal to 0 and that is not a RASL, RADL or SLNR picture.
- The short-term reference pictures in the RPS of the current picture.
- All pictures m that have PicOutputFlag equal to 1, AuCpbRemovalTime[m] less than AuCpbRemovalTime[currAu] and DpbOutputTime[m] greater than or equal to AuCpbRemovalTime[currAu], where currAu is the access unit containing the current picture, and AuCpbRemovalTime[m] and DpbOutputTime[m] are the CPB removal time and the DPB output time, respectively, of the access unit containing picture m.

The bitstream and the sub-bitstream of each output layer set are tested by the HRD for conformance as specified in clause C.1 and clause F.13.1. All the conditions specified in clause C.4 shall be fulfilled for each of the first and second sets of conformance tests. All of the following conditions shall be fulfilled for each of the third set of conformance tests:

1. For each partition unit n, with n greater than 0, associated with a buffering period SEI message, let the variable deltaTime90k[n] be specified as follows:

$$\text{deltaTime90k}[n] = 90\,000 * (\text{AuNominalRemovalTime}[n] - \text{AuFinalArrivalTime}[n-1]) \quad (\text{F-84})$$

The value of InitCpbRemovalDelay[SchedSelIdx] is constrained as follows:

- If cbr_flag[SchedSelIdx] is equal to 0, the following condition shall be true:

$$\text{InitCpbRemovalDelay}[\text{SchedSelIdx}] \leq \text{Ceil}(\text{deltaTime90k}[n]) \quad (\text{F-85})$$

- Otherwise (cbr_flag[SchedSelIdx] is equal to 1), the following condition shall be true:

$$\begin{aligned} \text{Floor}(\text{deltaTime90k}[n]) &\leq \text{InitCpbRemovalDelay}[\text{SchedSelIdx}] \\ &\leq \text{Ceil}(\text{deltaTime90k}[n]) \end{aligned} \quad (\text{F-86})$$

NOTE 1 – The exact number of bits in the BPB at the removal time of each partition unit may depend on which buffering period SEI message is selected to initialize the HRD. Encoders must take this into account to ensure that all

specified constraints must be obeyed regardless of which buffering period SEI message is selected to initialize the HRD, as the HRD may be initialized at any one of the buffering period SEI messages.

2. A BPB overflow is specified as the condition in which the total number of bits in the BPB is greater than the BPB size. The BPB shall never overflow.
3. When `low_delay_hrd_flag[HighestTid]` is equal to 0, the BPB shall never underflow. A BPB underflow is specified as follows:
 - If `SubHrdFlag` is equal to 0, a BPB underflow is specified as the condition in which the nominal BPB removal time of partition unit `n` `AuNominalRemovalTime[n]` is less than the final BPB arrival time of partition unit `n` `AuFinalArrivalTime[N]` for at least one value of `n`.
 - Otherwise (`SubHrdFlag` is equal to 1), a BPB underflow is specified as the condition in which the nominal BPB removal time of decoding unit `m` `DuNominalRemovalTime[m]` is less than the final BPB arrival time of decoding unit `m` `DuFinalArrivalTime[m]` for at least one value of `m`.
4. When `SubPicHrdFlag` is equal to 1, `low_delay_hrd_flag[HighestTid]` is equal to 1 and the nominal removal time of a decoding unit `m` of partition unit `n` is less than the final BPB arrival time of decoding unit `m` (i.e., `DuNominalRemovalTime[m] < DuFinalArrivalTime[m]`), the nominal removal time of partition unit `n` shall be less than the final BPB arrival time of partition unit `n` (i.e., `AuNominalRemovalTime[n] < AuFinalArrivalTime[n]`).
5. The nominal removal times of partition units from the BPB (starting from the second partition unit in decoding order) shall satisfy the constraints on `AuNominalRemovalTime[n]` and `AuCpbRemovalTime[n]` expressed in clauses A.4.1 through A.4.2 for bitstreams or layers conforming to profiles defined in Annex A, or expressed in clauses G.11.2.1 through G.11.2.2 for bitstreams or layers conforming to profiles defined in Annex G, or expressed in clauses H.11.2.1 through H.11.2.2 for bitstreams or layers conforming to profiles defined in Annex H.
6. For each current picture, after invocation of the process for removal of pictures from the sub-DPB as specified in clause F.13.3.2, the number of decoded pictures in the sub-DPB for the current layer, including all pictures `n`, where each picture `n` is contained in partition unit `kn`, in the current layer that are marked as "used for reference", or that have `PicOutputFlag` equal to 1 and `AuCpbRemovalTime[kn]` less than `AuCpbRemovalTime[currAu]`, where `currAu` is the partition unit containing the current picture, shall be less than or equal to `max_vps_dec_pic_buffering_minus1[TargetOlsIdx][layerIdx][HighestTid]`, where `layerIdx` is equal to the value such that `LayerSetLayerIdList[TargetDecLayerSetIdx][layerIdx]` is equal to `currPicLayerId`.
7. All reference pictures shall be present in the DPB when needed for prediction. Each picture that has `PicOutputFlag` equal to 1 shall be present in the DPB at its DPB output time unless it is removed from the DPB before its output time by one of the processes specified in clause F.13.3.
8. For each current picture that is not an IRAP picture with `NoRasOutputFlag` equal to 1 or that is not the first picture of the current layer with `nuh_layer_id` greater than 0 that follows an IRAP picture that has `nuh_layer_id` equal to 0 and has `NoClasOutputFlag` equal to 1, the value of `maxPicOrderCnt – minPicOrderCnt` shall be less than `MaxPicOrderCntLsb / 2`.
9. The value of `DpbOutputInterval[n]` as given by Equation F-83, which is the difference between the output time of a partition unit that has `AuOutputFlag` equal to 1 and that of the first partition unit following it in output order and having `AuOutputFlag` equal to 1, shall satisfy the constraint on `DpbOutputInterval[n]` expressed in clause A.4.2 for the profile, tier and level of the bitstream or layer using the decoding process specified in clauses 2 through 10, or expressed in clause G.11.2.2 for the profile, tier and level of the bitstream or layer using the decoding process specified in clauses F.2 through F.10 and either clauses G.2 through G.10 or clauses H.2 through H.10.
10. For each current picture, when `sub_pic_cpb_params_in_pic_timing_sei_flag` is equal to 1, let `tmpCpbRemovalDelaySum` be derived as follows:

$$\begin{aligned}
 &\text{tmpCpbRemovalDelaySum} = 0 \\
 &\text{for}(i = 0; i < \text{num_decoding_units_minus1}; i++) \\
 &\quad \text{tmpCpbRemovalDelaySum} += \text{du_cpb_removal_delay_increment_minus1}[i] + 1
 \end{aligned}
 \tag{F-87}$$

The value of `ClockSubTick * tmpCpbRemovalDelaySum` shall be equal to the difference between the nominal BPB removal time of the current partition unit and the nominal BPB removal time of the first decoding unit in the current partition unit in decoding order.

11. Let `picA` be an IRAP picture with `NoRasOutputFlag` equal to 1 and belonging to a layer `layerA`. Let `auB` be the earlier, in decoding order, of the first partition unit containing an IRAP picture with `nuh_layer_id` equal to 0 and `NoClasOutputFlag` equal to 1 that succeeds `picA` in decoding order and the first partition unit containing an IRAP picture with `NoRasOutputFlag` equal to 1 in `layerA` that succeeds `picA` in decoding order. For any two pictures `picM` and `picN` in the layer `layerA` contained in partition units `m` and `n`, respectively, that either are `picA` or succeed

picA in decoding order and precede auB in decoding order, when DpbOutputTime[m] is greater than DpbOutputTime[n], PicOrderCnt(picM) shall be greater than PicOrderCnt(picN), where PicOrderCnt(picM) and PicOrderCnt(picN) are the PicOrderCntVal values of picM and picN, respectively, immediately after the invocation of the decoding process for picture order count of the latter of picM and picN in decoding order.

NOTE 2 – All pictures of an earlier CVS in decoding order that are output are output before any pictures of a later CVS in decoding order. Within any particular CVS where all pictures have poc_reset_id not present or equal to 0, the pictures that are output are output in increasing PicOrderCntVal order. For any particular CVS where some pictures have poc_reset_id greater than 0, within each POC resetting period, the pictures that are output are output in increasing PicOrderCntVal order, and for any two pictures that are output and are in different POC resetting periods, the one that is earlier in decoding order is output earlier.

12. For any decoding unit m, DuCpbRemovalTime[m] shall be greater than or equal to the BPB removal time of the previous DU that precedes the current DU in decoding order and that is in the same bitstream partition as the decoding unit m or includes one or more VCL NAL units of a picture that may be used as a direct or indirect reference picture for the picture containing the one or more VCL NAL units included in the decoding unit m.
13. The DPB output times derived for all pictures in any particular access unit shall be the same.

F.13.5 Decoder conformance

F.13.5.1 General

A decoder conforming to this Specification shall fulfil all requirements specified in this clause.

A decoder claiming conformance to a specific profile, tier and level shall be able to successfully decode all bitstreams that conform to the bitstream conformance requirements specified in clause F.13.4, in the manner specified in Annexes A, G and H for profile, tier and level specified in Annexes A, G and H, respectively, provided that all VPSs, SPSs and PPSs referred to by the VCL NAL units, appropriate buffering period, picture timing and decoding unit information SEI messages are conveyed to the decoder, in a timely manner, either in the bitstream (by non-VCL NAL units), or by external means not specified in this Specification, and, when vps_base_layer_internal_flag is equal to 0, the decoded pictures with nuh_layer_id equal to 0 and their properties as specified in clause F.8.1 and its subclauses are conveyed to the decoder in a timely manner by external means not specified in this Specification.

When a bitstream contains syntax elements that have values that are specified as reserved and it is specified that decoders shall ignore values of the syntax elements or NAL units containing the syntax elements having the reserved values, and the bitstream is otherwise conforming to this Specification, a conforming decoder shall decode the bitstream in the same manner as it would decode a conforming bitstream and shall ignore the syntax elements or the NAL units containing the syntax elements having the reserved values as specified.

There are two types of conformance that can be claimed by a decoder: output timing conformance and output order conformance.

To check conformance of a decoder, test bitstreams containing one or more bitstream partitions conforming to the claimed profile, tier and level, as specified in clause F.13.4 are delivered by a hypothetical stream scheduler (HSS) both to the HRD and to the decoder under test (DUT). When vps_base_layer_internal_flag is equal to 0, decoded pictures with nuh_layer_id equal to 0 and their properties as specified in clause F.8.1 and its subclauses are also conveyed both to the HRD and to the DUT in a timely manner by external means not specified in this Specification. All cropped decoded pictures output by the HRD shall also be output by the DUT, each cropped decoded picture output by the DUT shall be a picture with PicOutputFlag equal to 1, and, for each such cropped decoded picture output by the DUT, the values of all samples that are output shall be equal to the values of the samples produced by the specified decoding process. The flag BaseLayerOutputFlag and all flags BaseLayerPicOutputFlag output by the HRD shall also be output by the DUT, and the values that are output shall be equal to the values produced by the specified decoding process.

For output timing decoder conformance, the HSS operates as described above, with delivery schedules selected only from the subset of values of SchedSelIdx for which the bit rate and CPB size are restricted as specified in Annexes A, G and H for the specified profile, tier and level in Annexes A, G and H, respectively, or with "interpolated" delivery schedules as specified below for which the bit rate and CPB size are restricted as specified in Annexes A, G and H for the specified profile, tier and level in Annexes A, G and H, respectively. The same delivery schedule is used for both the HRD and the DUT.

When the HRD parameters and the buffering period SEI messages are present with the number of signalled delivery schedules greater than 0, the decoder shall be capable of decoding each bitstream partition as delivered from the HSS operating using an "interpolated" delivery schedule specified as having peak bit rate r, CPB size c(r) and initial CPB removal delay (f(r) ÷ r) as follows:

$$\alpha = (r - \text{BitRate}[\text{SchedSelIdx} - 1]) \div (\text{BitRate}[\text{SchedSelIdx}] - \text{BitRate}[\text{SchedSelIdx} - 1]),$$

(F-88)

$$c(r) = \alpha * CpbSize[SchedSelIdx] + (1 - \alpha) * CpbSize[SchedSelIdx - 1], \quad (F-89)$$

$$f(r) = \alpha * InitCpbRemovalDelay[SchedSelIdx] * BitRate[SchedSelIdx] + (1 - \alpha) * InitCpbRemovalDelay[SchedSelIdx - 1] * BitRate[SchedSelIdx - 1] \quad (F-90)$$

for any SchedSelIdx > 0 and r such that BitRate[SchedSelIdx - 1] <= r <= BitRate[SchedSelIdx] such that r and c(r) are within the limits as specified in Annexes A, G and H for the maximum bit rate and buffer size for the specified profile, tier and level defined in Annexes A, G and H, respectively. The following applies for the specifications above:

- Let combIdx be any value in the range of 0 to num_bsp_schedules_minus1[TargetOlsIdx][TargetPsIdx][HighestTid], inclusive.
- SchedSelIdx shall be one of the values among bsp_sched_idx[TargetOlsIdx][TargetPsIdx][HighestTid][combIdx][j] for and j is the index of the bitstream partition index of TargetBitstreamPartition.
- SchedSelIdx - 1 is to be understood as bsp_sched_idx[TargetOlsIdx][TargetPsIdx][HighestTid][combIdx - 1][j] for any value of k in the range of 1 to combIdx, inclusive.

NOTE 1 – InitCpbRemovalDelay[SchedSelIdx] can be different from one buffering period to another and need to be recalculated.

For output timing decoder conformance, an HRD as described above is used and the timing (relative to the delivery time of the first bit) of picture output is the same for both the HRD and the DUT up to a fixed delay.

For output order decoder conformance, the following applies for each bitstream partition in TargetPartitioningScheme:

- The HSS delivers the TargetBitstreamPartition to the DUT "by demand" from the DUT, meaning that the HSS delivers bits (in decoding order) only when the DUT requires more bits to proceed with its processing.
NOTE 2 – This means that for this test, the coded picture buffer of the DUT could be as small as the size of the largest decoding unit.
- A modified HRD as described below is used, and the HSS delivers the bitstream to the HRD by one of the schedules specified in the TargetBitstreamPartition such that the bit rate and CPB size are restricted as specified in Annex A for profiles defined in Annex A, Annex G for profiles defined in Annex G and Annex H for profiles defined in Annex H. The order of pictures output shall be the same for both the HRD and the DUT.
- The HRD BPB size is given by CpbSize[SchedSelIdx] as specified in clause F.13.1. The sub-DPB size of the sub-DPB for a layer with nuh_layer_id equal to currLayerId is max_vps_dec_pic_buffering_minus1[TargetOlsIdx][layerIdx][HighestTid] + 1, where layerIdx is equal to the value such that LayerSetLayerIdList[TargetDecLayerSetIdx][layerIdx] is equal to currLayerId. The removal time from the CPB for the HRD is the final bit arrival time and decoding is immediate. The operation of the DPB of this HRD is as described in the subclauses of clause F.13.5.2.

F.13.5.2 Operation of the output order DPB

F.13.5.2.1 General

The decoded picture buffer consists of sub-DPBs and each sub-DPB contains picture storage buffers for storage of decoded pictures of one layer. Each of the picture storage buffers of a sub-DPB contains a decoded picture that is marked as "used for reference" or is held for future output.

The process for output and removal of pictures from the DPB before decoding of the current picture as specified in clause F.13.5.2.2 is invoked, followed by the invocation of the process for current decoded picture marking and storage as specified in clause F.13.3.4, further followed by the invocation of the process for removal of pictures from the DPB after decoding of the current picture as specified in clause F.13.3.5, and finally followed by the invocation of the process for additional bumping as specified in clause F.13.5.2.3. The "bumping" process is specified in clause F.13.5.2.4 and is invoked as specified in clauses F.13.5.2.2 and F.13.5.2.3.

These processes are applied independently for each layer, starting from the base layer, in increasing order of the nuh_layer_id values of the layers in the bitstream. When these processes are applied for a particular layer, only the sub-DPB for the particular layer is affected except for the "bumping" process, which may crop and output pictures, mark pictures as "not needed for output" and empty picture storage buffers for any layer.

NOTE – In the operation of output order DPB, same as in the operation of output timing DPB, decoded pictures with PicOutputFlag equal to 1 in the same access unit are also output consecutively in ascending order of the nuh_layer_id values of the decoded pictures.

Let picture n and the current picture be the coded picture or decoded picture of the access unit n for a particular value of nuh_layer_id, wherein n is a non-negative integer number.

When these processes are applied for a layer with nuh_layer_id equal to currLayerId, the variables MaxNumReorderPics, MaxLatencyIncreasePlus1, MaxLatencyValue and MaxDecPicBufferingMinus1 are derived as follows:

- MaxNumReorderPics is set equal to max_vps_num_reorder_pics[TargetOlsIdx][HighestTid] of the active VPS.

- MaxLatencyIncreasePlus1 is set equal to the value of the syntax element `max_vps_latency_increase_plus1[TargetOlsIdx][HighestTid]` of the active VPS.
- MaxLatencyValue is set equal to `MaxVpsLatencyPictures[TargetOlsIdx][HighestTid]` of the active VPS.
- MaxDecPicBufferingMinus1 is set equal to the value of the syntax element `max_vps_dec_pic_buffering_minus1[TargetOlsIdx][layerIdx][HighestTid]` of the active VPS, where `layerIdx` is equal to the value such that `LayerSetLayerIdList[TargetDecLayerSetIdx][layerIdx]` is equal to `currLayerId`.

F.13.5.2.2 Output and removal of pictures from the DPB before decoding of the current picture

When the current picture is not picture 0 in the current layer, the output and removal of pictures in the current layer, with `nuh_layer_id` equal to `currLayerId`, from the DPB before the decoding of the current picture, i.e., picture `n`, but after parsing the slice header of the first slice of the current picture and before the invocation of the decoding process for picture order count, happens instantaneously when the first decoding unit of the current picture is removed from the CPB and proceeds as follows:

- When the current picture is a POC resetting picture, all pictures in the DPB that do not belong to the current access unit and that are marked as "needed for output" are output, starting with pictures with the smallest value of `PicOrderCntVal` of all pictures excluding those in the current access unit in the DPB, in ascending order of the `PicOrderCntVal` values, and pictures with the same value of `PicOrderCntVal` are output in ascending order of the `nuh_layer_id` values. When a picture is output, it is cropped using the conformance cropping window specified in the active SPS for the picture, the cropped picture is output, and the picture is marked as "not needed for output".
- The decoding processes for picture order count and RPS are invoked. When decoding a CVS conforming to one or more of the profiles specified in Annex A using the decoding process specified in clauses 2 through 10, the decoding processes for picture order count and RPS that are invoked are as specified in clauses 8.3.1 and 8.3.2, respectively. When decoding a CVS conforming to one or more of the profiles specified in Annex G or H using the decoding process specified in Annex F, and Annex G or H, the decoding processes for picture order count and RPS that are invoked are as specified in clauses F.8.3.1 and F.8.3.2, respectively.
- The variable `listOfSubDpbsToEmpty` is derived as follows:
 - If a new VPS is activated by the current access unit or the current picture is IRAP picture with `nuh_layer_id` equal to `SmallestLayerId`, `NoRasOutputFlag` equal to 1 and `NoClasOutputFlag` equal to 1, `listOfSubDpbsToEmpty` is set equal to all the sub-DPBs.
 - Otherwise, if the current picture is an IRAP picture with any `nuh_layer_id` value `indepLayerId` such that `NumDirectRefLayers[indepLayerId]` is equal to 0 and `indepLayerId` is greater than `SmallestLayerId`, and with `NoRasOutputFlag` equal to 1, and `LayerResetFlag` is equal to 1, `listOfSubDpbsToEmpty` is set equal to the sub-DPBs containing the current layer and the sub-DPBs containing the predicted layers of the current layer.
 - Otherwise, `listOfSubDpbsToEmpty` is set equal to the sub-DPB containing the current layer.
- If the current picture is an IRAP picture with `NoRasOutputFlag` equal to 1 and any of the following conditions is true:
 - `nuh_layer_id` equal to `SmallestLayerId`,
 - `nuh_layer_id` of the current layer is greater than `SmallestLayerId` and `NumDirectRefLayers[nuh_layer_id]` is equal to 0,

the following ordered steps are applied:

1. The variable `NoOutputOfPriorPicsFlag` is derived for the decoder under test as follows:
 - If the current picture is a CRA picture, `NoOutputOfPriorPicsFlag` is set equal to 1 (regardless of the value of `no_output_of_prior_pics_flag`).
 - Otherwise, if the value of `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `chroma_format_idc`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `separate_colour_plane_flag` or `sps_max_dec_pic_buffering_minus1[HighestTid]` derived from the active SPS for the current layer is different from the value of `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `chroma_format_idc`, `bit_depth_luma_minus8`, `bit_depth_chroma_minus8`, `separate_colour_plane_flag` or `sps_max_dec_pic_buffering_minus1[HighestTid]`, respectively, derived from the SPS that was active for the current layer when decoding the preceding picture in the current layer, `NoOutputOfPriorPicsFlag` may (but should not) be set equal to 1 by the decoder under test, regardless of the value of `no_output_of_prior_pics_flag`.

NOTE – Although setting `NoOutputOfPriorPicsFlag` equal to `no_output_of_prior_pics_flag` is preferred under these conditions, the decoder under test is allowed to set `NoOutputOfPriorPicsFlag` to 1 in this case.

- Otherwise, NoOutputOfPriorPicsFlag is set equal to no_output_of_prior_pics_flag.
- 2. The value of NoOutputOfPriorPicsFlag derived for the decoder under test is applied for the HRD as follows:
 - If NoOutputOfPriorPicsFlag is equal to 0, all non-empty picture storage buffers in all the sub-DPBs included in listOfSubDpbsToEmpty are output by repeatedly invoking the "bumping" process specified in clause F.13.5.2.4 until all these pictures are marked as "not needed for output".
 - Otherwise (NoOutputOfPriorPicsFlag is equal to 1), all picture storage buffers containing a picture that is marked as "not needed for output" and "unused for reference" are emptied (without output), all pictures that are contained in a sub-DPB included in listOfSubDpbsToEmpty are emptied, and the sub-DPB fullness of each sub-DPB is decremented by the number of picture storage buffers emptied in that sub-DPB.
- Otherwise, all picture storage buffers that contain a picture in the current layer and that are marked as "not needed for output" and "unused for reference" are emptied (without output). For each picture storage buffer that is emptied, the sub-DPB fullness is decremented by one. When one or more of the following conditions are true, the "bumping" process specified in clause F.13.5.2.4 is invoked repeatedly until none of the following conditions are true:
 - The number of access units that contain at least one decoded picture in the DPB marked as "needed for output" is greater than MaxNumReorderPics.
 - MaxLatencyIncreasePlus1 is not equal to 0 and there is at least one access unit that contains at least one decoded picture in the DPB marked as "needed for output" for which the associated variable PicLatencyCount is greater than or equal to MaxLatencyValue.
 - The number of pictures in the sub-DPB is greater than or equal to MaxDecPicBufferingMinus1 + 1 – TwoVersionsOfCurrDecPicFlag.

F.13.5.2.3 Additional bumping

The processes specified in this clause happen instantaneously when the last decoding unit of picture *n* is removed from the CPB.

When the current picture is the last picture in an access unit, the following applies for each decoded picture with *nuh_layer_id* greater than or equal to (*vps_base_layer_internal_flag* ? 0 : 1) of the access unit:

- If the decoded picture has PicOutputFlag equal to 1, it is marked as "needed for output".
- Otherwise (the decoded picture has PicOutputFlag equal to 0), it is marked as "not needed for output".

NOTE – Prior to investigating the conditions above, PicOutputFlag of each picture of the access unit is updated as specified in clause F.8.1.2.

When one or more of the following conditions are true, the "bumping" process specified in clause F.13.5.2.4 is invoked repeatedly until none of the following conditions are true:

- The number of access units that contain at least one decoded picture in the DPB marked as "needed for output" is greater than MaxNumReorderPics.
- MaxLatencyIncreasePlus1 is not equal to 0 and there is at least one access unit that contains at least one decoded picture in the DPB marked as "needed for output" for which the associated variable PicLatencyCount is greater than or equal to MaxLatencyValue.

F.13.5.2.4 "Bumping" process

The "bumping" process consists of the following ordered steps:

1. The picture or pictures that are first for output are selected as the ones having the smallest value of PicOrderCntVal of all pictures in the DPB marked as "needed for output".
2. Each of these pictures is, in ascending *nuh_layer_id* order, cropped, using the conformance cropping window specified in the active SPS for the picture, the cropped picture is output and the picture is marked as "not needed for output".
3. Each picture storage buffer that contains a picture marked as "unused for reference" and that was one of the pictures cropped and output is emptied and the fullness of the associated sub-DPB is decremented by one.

F.13.6 Demultiplexing process for deriving a bitstream partition

Inputs to this process are a bitstream, a layer identifier list *bspLayerId*[*bspIdx*] and the number of layer identifiers *numBspLayers* in the layer index list *bspLayerId*[*bspIdx*].

Output of this process is a bitstream partition.

Let the variable *minBspLayerId* be the smallest value of *bspLayerId*[*bspIdx*] with any value of *bspIdx* in the range of 0 to *numBspLayers* – 1, inclusive.

The output bitstream partition consists of selected NAL units of the input bitstream in the same order as they appear in the input bitstream. The following NAL units of the input bitstream are omitted from the output bitstream partition, while the remaining NAL units of the input bitstream are included in the output bitstream partition:

- Omit all NAL units that have a `nuh_layer_id` value other than `bspLayerId[bspIdx]` with any value of `bspIdx` in the range of 0 to `numBspLayers – 1`, inclusive.
- Omit all SEI NAL units containing a scalable nesting SEI message for which no derived `nestingLayerIdList[i]` contains any layer identifier value equal to `bspLayerId[bspIdx]` with any value of `bspIdx` in the range of 0 to `numBspLayers – 1`, inclusive.
- Omit all SEI NAL units containing a scalable nesting SEI message for which a derived `nestingLayerIdList[i]` contains a layer identifier value less than `minBspLayerId`.

F.14 Supplemental enhancement information

F.14.1 General

The specifications in clause D.1 apply.

F.14.2 SEI payload syntax

F.14.2.1 General SEI payload syntax

The specifications in clause D.2.1 apply.

F.14.2.2 Annex D SEI message syntax for multi-layer extensions

The specifications in clauses D.2.2 through D.2.49 apply.

F.14.3 SEI payload semantics

F.14.3.1 General SEI payload semantics

The general SEI payload semantics specified in clause D.3.1 apply with the following modifications and additions:

The list VclAssociatedSeiList is set to consist of the payloadType values 2, 3, 6, 9, 15, 16, 17, 19, 22, 23, 45, 47, 56, 128, 131, 132, 134 to 152, inclusive, 154 to 159, inclusive, 161, 165, 167, 168, 200 to 202, inclusive, and 205.

The list PicUnitRepConSeiList is set to consist of the payloadType values 0, 1, 2, 6, 9, 15, 16, 17, 19, 22, 23, 45, 47, 56, 128, 129, 131, 132, 133, 135 to 152, inclusive, 154 to 168, inclusive, 200 to 202, inclusive, and 205.

The semantics and persistence scope for each SEI message specified in this annex are specified in the semantics specification for each particular SEI message in clauses F.14.3.3 to F.14.3.11, inclusive.

NOTE – Persistence information for SEI messages specified in this annex is informatively summarized in Table F.4.

Table F.4 – Persistence scope of SEI messages (informative)

SEI message	Persistence scope
Layers not present	Specified by the semantics of the SEI message
Inter-layer constrained tile sets	The CLVS associated with the SEI message
Bitstream partition nesting	Each SEI message contained in the bitstream partition nesting SEI message has the same persistence scope as if the SEI message was not contained in the bitstream partition nesting SEI message
Bitstream partition initial arrival time	The remainder of the bitstream partition (specified by the containing bitstream partition nesting SEI message)
Sub-bitstream property	The CVS containing the SEI message
Alpha channel information	Specified by the syntax of the SEI message
Overlay information	Specified by the syntax of the SEI message
Temporal motion vector prediction constraints	Specified by the semantics of the SEI message
Frame-field information	The access unit containing the SEI message

Let prevVclNalUnitInAu of an SEI NAL unit or an SEI message be the preceding VCL NAL unit in decoding order, if any, in the same access unit, and nextVclNalUnitInAu of an SEI NAL unit or an SEI message be the next VCL NAL unit in decoding order, if any, in the same access unit. It is a requirement of bitstream conformance that the following restrictions apply:

- When a buffering period SEI message, a picture timing SEI message, a decoding unit information SEI message or a bitstream partition initial arrival time SEI message is present in a bitstream partition nesting SEI message contained in a scalable nesting SEI message, the scalable nesting SEI message shall not follow any other SEI message that

follows the prevVclNalUnitInAu of the scalable nesting SEI message and precedes the nextVclNalUnitInAu of the scalable nesting SEI message, other than an active parameter sets SEI message, a non-scalable-nested buffering period SEI message, a non-scalable-nested picture timing SEI message, a non-scalable-nested decoding unit information SEI message, a scalable nesting SEI message including a buffering period SEI message, a picture timing SEI message, a decoding unit information SEI message or another scalable nesting SEI message that contains a bitstream partition nesting SEI message including a buffering period SEI message, a picture timing SEI message, a decoding unit information SEI message or a bitstream partition initial arrival time SEI message.

F.14.3.2 Annex D SEI message semantics for multi-layer extensions

F.14.3.2.1 General

The semantics of SEI messages specified in clauses D.3.2 through D.3.49 apply with the modifications specified in clauses F.14.3.2.2 through F.14.3.2.8.

F.14.3.2.2 Buffering period SEI message semantics for multi-layer extensions

The specifications of clause D.3.2 apply with the following modifications and additions:

When the buffering period SEI message is directly contained in a scalable nesting SEI message within an SEI NAL unit with a nuh_layer_id value targetNuhLayerId greater than 0, the semantics of clause D.3.2 apply to the output bitstream of the independent non-base layer rewriting process of clause F.10.2 with the input variables assignedBaseLayerId equal to nestingLayerIdList[i][0] and tldTarget equal to MaxTemporalId[i] for each value of i in the range of 0 to nestingNumOps – 1, inclusive.

When the buffering period SEI message is contained in a bitstream partition nesting SEI message, the following applies:

- A set of skipped leading pictures skippedPictureList consists of the CL-RAS pictures and the RASL pictures associated with the IRAP pictures with nuh_layer_id equal to nuhLayerId for which LayerInitializedFlag[nuhLayerId] is equal to 0 at the start of decoding the IRAP picture and for which nuhLayerId is among the nestingLayerIdList[i] for any value of i in the range of 0 to nesting_num_ops_minus1, inclusive.
- A picture is said to be a notDiscardablePic picture when the picture has TemporalId equal to 0, has discardable_flag equal to 0, and is not a RASL, RADL or SLNR picture.
- The variables olsIdx, psIdx and bspIdx are set equal to sei_ols_idx, sei_partitioning_scheme_idx and bsp_idx, respectively, of the bitstream partition nesting SEI message containing this buffering period SEI message and the bspIdx-th bitstream partition of the psIdx-th partitioning scheme of the olsIdx-th OLS is referred to as the current bitstream partition.
- The variable maxTId is set equal to MaxTemporalId[0] for the scalable nesting SEI message containing the bitstream partition nesting SEI message containing this buffering period SEI message.
- The variable CpbCnt is set equal to BspSchedCnt[olsIdx][psIdx][maxTId] for the syntax and semantics of the buffering period SEI message and for the constraints specified below.
- The variable hrdParamIdx[i] is set equal to the value of bsp_hrd_idx[olsIdx][psIdx][maxTId][i][bspIdx] for each value of i in the range of 0 to CpbCnt – 1, inclusive.
- The syntax elements au_cpb_removal_delay_length_minus1, dpb_output_delay_length_minus1 and sub_pic_hrd_params_present_flag are found in or derived from the hrdParamIdx[i]-th hrd_parameters() syntax structure for any value of i in the range of 0 to CpbCnt – 1, inclusive. It is a requirement of bitstream conformance that the values of au_cpb_removal_delay_length_minus1, dpb_output_delay_length_minus1 and sub_pic_hrd_params_present_flag derived using a particular value of i shall be the same as the value of the respective syntax elements derived using any other allowed value of i.
- The syntax element initial_cpb_removal_delay_length_minus1 is found in or derived from the hrdParamIdx[i]-th hrd_parameters() syntax structure for the semantics of nal_initial_cpb_removal_delay[i], nal_initial_alt_cpb_removal_delay[i], nal_initial_cpb_removal_offset[i], nal_initial_alt_cpb_removal_offset[i], vcl_initial_cpb_removal_delay[i], vcl_initial_alt_cpb_removal_delay[i], vcl_initial_cpb_removal_offset[i] and vcl_initial_alt_cpb_removal_offset[i].
- The variable CpbSize[i] is set equal to BpbSize[olsIdx][psIdx][maxTId][i][bspIdx] for the semantics of nal_initial_cpb_removal_delay[i], nal_initial_alt_cpb_removal_delay[i], vcl_initial_cpb_removal_delay[i] and vcl_initial_alt_cpb_removal_delay[i].
- The variable BitRate[i] is set equal to BpBitRate[olsIdx][psIdx][maxTId][i][bspIdx] for the semantics of nal_initial_cpb_removal_delay[i], nal_initial_alt_cpb_removal_delay[i], vcl_initial_cpb_removal_delay[i] and vcl_initial_alt_cpb_removal_delay[i].

- The variables `NalHrdBpPresentFlag` and `VclHrdBpPresentFlag` are derived from the `hrdParamIdx[i]`-th `hrd_parameters()` syntax structure for any value of `i` in the range of 0 to `CpbCnt – 1`, inclusive. It is a requirement of bitstream conformance that the value of `NalHrdBpPresentFlag` shall be the same regardless of the value of `i` used in its derivation. It is a requirement of bitstream conformance that the value of `VclHrdBpPresentFlag` shall be the same regardless of the value of `i` used in its derivation.

The presence of buffering period SEI messages for the current bitstream partition is specified as follows on the basis of the variables `NalHrdBpPresentFlag` and `VclHrdBpPresentFlag` that are derived as specified above:

- If `NalHrdBpPresentFlag` is equal to 1 or `VclHrdBpPresentFlag` is equal to 1, the following applies for each access unit in the CVS:
 - If the access unit is an IRAP access unit, a buffering period SEI message applicable to the current bitstream partition shall be associated with the access unit.
 - Otherwise, if the access unit contains a `notDiscardablePic` in at least one layer included in the current bitstream partition, a buffering period SEI message applicable to the current bitstream partition may or may not be associated with the access unit.
 - Otherwise, the access unit shall not be associated with a buffering period SEI message applicable to the current bitstream partition.
- Otherwise (`NalHrdBpPresentFlag` and `VclHrdBpPresentFlag` are both equal to 0), no access unit in the CVS shall be associated with a buffering period SEI message applicable to the current bitstream partition.

When the buffering period SEI message is contained in a bitstream partition nesting SEI message, the following semantics of `concatenation_flag` and `au_cpb_removal_delay_delta_minus1` replace those specified in clause D.3.2 and the following specifications apply to each picture `currPic` with `nuh_layed_id` `currNuhLayerId` equal to any value included in the current bitstream partition in the current access unit.

When the picture `currPic` with `nuh_layer_id` equal to `targetLayerId` in the current access unit is not the first picture with that `nuh_layer_id` value in the bitstream in decoding order, let `prevNonDiscardablePic` be the preceding picture in decoding order with that `nuh_layer_id` value and with `TemporalId` equal to 0 that is not a RASL, RADL or SLNR picture.

concatenation_flag indicates, when the picture `currPic` is not the first picture with `nuh_layer_id` equal to `currNuhLayerId` in the bitstream in decoding order, whether the nominal CPB removal time of the current picture is determined relative to the nominal CPB removal time of the preceding picture with a buffering period SEI message that applies to the current bitstream partition, or relative to the nominal CPB removal time of the picture `prevNonDiscardablePic`.

au_cpb_removal_delay_delta_minus1 plus 1, when the picture `currPic` is not the first picture with `nuh_layer_id` equal to `currNuhLayerId` in the bitstream in decoding order, specifies a CPB removal delay increment value relative to the nominal CPB removal time of the picture `prevNonDiscardablePic`. This syntax element has a length in bits given by `au_cpb_removal_delay_length_minus1 + 1`.

When the buffering period SEI message is contained in a bitstream partition nesting SEI message and `concatenation_flag` is equal to 0 and the picture `currPic` is not the first picture with `nuh_layer_id` equal to `currNuhLayerId` in the bitstream in decoding order, it is a requirement of bitstream conformance that the following constraint applies:

- If the picture `prevNonDiscardablePic` is not associated with a buffering period SEI message that applies the current bitstream partition, the `au_cpb_removal_delay_minus1` of the picture `currPic` shall be equal to the `au_cpb_removal_delay_minus1` of `prevNonDiscardablePic`, indicated in the picture timing SEI message applicable to the current bitstream partition, plus `au_cpb_removal_delay_delta_minus1 + 1`.
- Otherwise, `au_cpb_removal_delay_minus1`, indicated for the picture `currPic` in the picture timing SEI message applicable to the current bitstream partition, shall be equal to `au_cpb_removal_delay_delta_minus1`.

F.14.3.2.3 Picture timing SEI message semantics for multi-layer extensions

The specifications of clause D.3.3 apply with the following modifications and additions:

When the picture timing SEI message is directly contained in a scalable nesting SEI message within an SEI NAL unit with a `nuh_layer_id` value `targetNuhLayerId` greater than 0, the semantics of clause D.3.3 apply to the output bitstream of the independent non-base layer rewriting process of clause F.10.2 with the input variables `assignedBaseLayerId` equal to `nestingLayerIdList[i][0]` and `tIdTarget` equal to `MaxTemporalId[i]` for each value of `i` in the range of 0 to `nestingNumOps – 1`, inclusive.

When the picture timing SEI message is contained in a bitstream partition nesting SEI message, the following applies:

- `frame_field_info_present_flag` is inferred to be equal to 0 for the syntax and semantics of the picture timing SEI message.

NOTE 1 – The frame-field information SEI message can be used to indicate the frame-field information.

- The variables `olsIdx`, `psIdx` and `bspIdx` are set equal to `sei_ols_idx`, `sei_partitioning_scheme_idx` and `bsp_idx`, respectively, of the bitstream partition nesting SEI message containing this buffering period SEI message, and the `bspIdx`-th bitstream partition of the `psIdx`-th partitioning scheme of the `olsIdx`-th OLS is referred to as the current bitstream partition.
- The variable `maxTid` is set equal to `MaxTemporalId[0]` for the scalable nesting SEI message containing the bitstream partition nesting SEI message containing this buffering period SEI message.
- The variable `hrdParamIdx` is set equal to the value of `bsp_hrd_idx[olsIdx][psIdx][maxTid][i][bspIdx]` for any value of `i` in the range of 0 to `BspSchedCnt[olsIdx][psIdx][maxTid] – 1`, inclusive.
- The following applies for the syntax and semantics of the picture timing SEI message:
 - The syntax elements `sub_pic_hrd_params_present_flag`, `sub_pic_cpb_params_in_pic_timing_sei_flag`, `au_cpb_removal_delay_length_minus1`, `dpb_output_delay_length_minus1`, `dpb_output_delay_du_length_minus1`, `du_cpb_removal_delay_increment_length_minus1` and the variable `CpbDpbDelaysPresentFlag` are found in or derived from syntax elements found in the `hrdParamIdx`-th `hrd_parameters()` syntax structure.
 - It is a requirement of bitstream conformance that the values of `sub_pic_hrd_params_present_flag`, `sub_pic_cpb_params_in_pic_timing_sei_flag`, `au_cpb_removal_delay_length_minus1`, `dpb_output_delay_length_minus1`, `dpb_output_delay_du_length_minus1`, `du_cpb_removal_delay_increment_length_minus1` and `CpbDpbDelaysPresentFlag` derived using a particular value of `i` for the derivation of `hrdParamIdx` shall be the same as the value of the respective syntax elements or variable derived using any other allowed value of `i`.

The presence of picture timing SEI messages for the current bitstream partition is specified as follows on the basis of the variable `CpbDpbDelaysPresentFlag` that is derived as specified above:

- If `CpbDpbDelaysPresentFlag` is equal to 1, a picture timing SEI message applicable to the current bitstream partition shall be associated with every access unit in the CVS.
- Otherwise, in the CVS there shall be no access unit that is associated with a picture timing SEI message applicable to the current bitstream partition.

The semantics of `num_decoding_units_minus1` and `num_nalus_in_du_minus1[i]` are replaced with the following:

The variables `targetUnit` and `totalSizeInCtbsY` are derived as follows:

- If the picture timing SEI message is associated with a partition unit, `targetUnit` is set to be the partition unit and the value of `totalSizeInCtbsY` is set equal to the sum of the `PicSizeInCtbsY` of all pictures in the partition unit.
- Otherwise (the picture timing SEI message is associated with an access unit), `targetUnit` is set to be the access unit and the value of `totalSizeInCtbsY` is set equal to the sum of the `PicSizeInCtbsY` of all pictures in the access unit.

`num_decoding_units_minus1` plus 1 specifies the number of decoding units in `targetUnit`. The value of `num_decoding_units_minus1` shall be in the range of 0 to `totalSizeInCtbsY – 1`, inclusive.

`num_nalus_in_du_minus1[i]` plus 1 specifies the number of NAL units in the `i`-th decoding unit of `targetUnit`. The value of `num_nalus_in_du_minus1[i]` shall be in the range of 0 to `totalSizeInCtbsY – 1`, inclusive.

The first decoding unit of `targetUnit` consists of the first `num_nalus_in_du_minus1[0] + 1` consecutive NAL units in decoding order in `targetUnit`. The `i`-th (with `i` greater than 0) decoding unit of `targetUnit` consists of the `num_nalus_in_du_minus1[i] + 1` consecutive NAL units immediately following the last NAL unit in the previous decoding unit of `targetUnit`, in decoding order. There shall be at least one VCL NAL unit in each decoding unit. All non-VCL NAL units associated with a VCL NAL unit shall be included in the same decoding unit as the VCL NAL unit.

F.14.3.2.4 Recovery point SEI message semantics for multi-layer extensions

The recovery point SEI message assists a decoder in determining when the decoding process will produce acceptable pictures in the current layer for display after the decoder initiates random access, layer up-switching or after the encoder indicates a broken link.

When all decoded pictures in earlier access units in decoding order are removed from the bitstream, the recovery point picture (defined below) and all the subsequent pictures in output order in the current layer can be correctly or approximately correctly decoded, the current picture is referred to as a layer random-accessing picture. When all the pictures that belong to the reference layers of the current layer and may be used for reference by the current picture or subsequent pictures in decoding order are correctly decoded, and the recovery point picture and all the subsequent pictures in output order in the current layer can be correctly or approximately correctly decoded when no picture prior to the current picture in decoding order in the current layer are present in the bitstream, the current picture is referred to as a layer up-switching picture.

When the recovery point SEI message applies to the current layer and all the reference layers of the current layer, the current picture is indicated as a layer random-accessing picture. When the recovery point SEI message applies to the current layer but not to all the reference layers of the current layer, the current picture is indicated as a layer up-switching picture.

Decoded pictures in the current layer produced by random access or layer up-switching at or before the current access unit does not need to be correct in content until the indicated recovery point, and the operation of the decoding process for pictures in the current layer starting at the current picture may contain references to pictures unavailable in the decoded picture buffer.

In addition, by use of the `broken_link_flag`, the recovery point SEI message can indicate to the decoder the location of some pictures in the current layer in the bitstream that can result in serious visual artefacts when displayed, even when the decoding process was begun at the location of a previous IRAP access unit in decoding order that contain IRAP pictures in all layers.

NOTE 1 – The `broken_link_flag` can be used by encoders to indicate the location of a point after which the decoding process for the decoding of some pictures in the current layer may cause references to pictures that, though available for use in the decoding process, are not the pictures that were used for reference when the bitstream was originally encoded (e.g., due to a splicing operation performed during the generation of the bitstream).

When the current picture is a layer random access-accessing picture and random access is performed to start decoding from the current access unit, the decoder operates as if the current access unit was the first access unit in the bitstream in decoding order, and the following applies:

- If `poc_msb_cycle_val` is present for the current picture, the `PicOrderCntVal` of the current picture is derived as specified in the process for derivation of `PicOrderCntVal` in clause F.8.3.1.
- Otherwise (`poc_msb_cycle_val` is not present for the current picture), the variable `PrevPicOrderCnt[nuh_layer_id]` used in derivation of `PicOrderCntVal` for each picture in the access unit is set equal to 0.

NOTE 2 – When HRD information is present in the bitstream, a buffering period SEI message should be associated with the access unit associated with the recovery point SEI message in order to establish initialization of the HRD buffer model after a random access.

When the current picture is either a layer random-accessing picture or a layer up-switching picture and layer up-switching is performed to start decoding of the current layer from the current access (while decoding of the reference layers of the current layer have started earlier and pictures of those layers in the current access unit are correctly decoded), the decoder operates as if the current picture was the first picture of the current layer in the bitstream in decoding order, and the `PicOrderCntVal` of the current picture is set equal to the `PicOrderCntVal` of any other decoded picture in the current access unit.

For a particular access unit `auA`, let `auB` be the first access unit that succeeds `auA` in decoding order such that the picture order count values of the pictures in `auB` can be derived without using the picture order count values of pictures preceding `auB` in decoding order. For a particular layer `layerA`, `auA` is not allowed to contain a recovery point SEI message that applies to a set of layers containing at least `layerA` and all reference layers of `layerA` when all of the following conditions are true:

- All pictures in `auA` that are in the reference layers, if any, of `layerA` have both `poc_msb_cycle_val_present_flag` and `poc_reset_idc` equal to 0.
- There is at least one picture `picA` with `poc_msb_cycle_val_present_flag` equal to 1 in the following access units:
 - Access units that follow `auA` in decoding order and precede `auB`, when present, in decoding order.
 - Access unit `auB`, when present and when picture in `auB` with `nuh_layer_id` equal to 0 is not an IRAP picture with `NoCllasOutputFlag` equal to 1.

Any SPS or PPS RBSP that is referred to by a picture of the access unit containing a recovery point SEI message or by any picture in a subsequent access unit in decoding order shall be available to the decoding process prior to its activation, regardless of whether or not the decoding process is started at the beginning of the bitstream or with the access unit, in decoding order, that contains the recovery point SEI message.

recovery_poc_cnt specifies the recovery point of decoded pictures in the current layer in output order. If there is a picture `picB` in the current layer that follows the current picture `picA` but precedes an access unit containing an IRAP picture in the current layer in decoding order and `PicOrderCnt(picB)` is equal to `PicOrderCnt(picA)` plus the value of `recovery_poc_cnt`, where `PicOrderCnt(picA)` and `PicOrderCnt(picB)` are the `PicOrderCntVal` values of `picA` and `picB`, respectively, immediately after the invocation of the decoding process for picture order count for `picB`, the picture `picB` is referred to as the recovery point picture. Otherwise, the first picture `picC` in the current layer in output order for which `PicOrderCnt(picC)` is greater than `PicOrderCnt(picA)` plus the value of `recovery_poc_cnt` is referred to as the recovery point picture, where `PicOrderCnt(picA)` and `PicOrderCnt(picC)` are the `PicOrderCntVal` values of `picA` and `picC`, respectively, immediately after the invocation of the decoding process for picture order count for `picC`. The recovery point picture shall not precede the current picture in decoding order. All decoded pictures in the current layer in output order are

indicated to be correct or approximately correct in content starting at the output order position of the recovery point picture. The value of `recovery_poc_cnt` shall be in the range of $-\text{MaxPicOrderCntLsb} / 2$ to $\text{MaxPicOrderCntLsb} / 2 - 1$, inclusive.

exact_match_flag indicates whether decoded pictures in the current layer at and subsequent to the specified recovery point in output order derived by starting the decoding process at the access unit containing the recovery point SEI message will be an exact match to the pictures in the current layer that would be produced by starting the decoding process at the location of a previous access unit where the picture of the layer in the current layer and the pictures of all the reference layers are IRAP pictures, if any, in the bitstream. The value 0 indicates that the match may not be exact and the value 1 indicates that the match will be exact. When `exact_match_flag` is equal to 1, it is a requirement of bitstream conformance that the decoded pictures in the current layer at and subsequent to the specified recovery point in output order derived by starting the decoding process at the access unit containing the recovery point SEI message shall be an exact match to the pictures in the current layer that would be produced by starting the decoding process at the location of a previous access unit where the picture in the current layer and the pictures of all the reference layers are IRAP pictures, if any, in the bitstream.

NOTE 3 – When performing random access, decoders should infer all references to unavailable pictures as references to pictures containing only intra coding blocks and having sample values given by Y equal to $(1 \ll (\text{BitDepth}_Y - 1))$, Cb and Cr both equal to $(1 \ll (\text{BitDepth}_C - 1))$ (mid-level grey), regardless of the value of `exact_match_flag`.

When `exact_match_flag` is equal to 0, the quality of the approximation at the recovery point is chosen by the encoding process and is not specified in this Specification.

broken_link_flag indicates the presence or absence of a broken link in the current layer at the location of the recovery point SEI message and is assigned further semantics as follows:

- If `broken_link_flag` is equal to 1, pictures in the current layer produced by starting the decoding process at the location of a previous access unit where the picture in the current layer and the pictures of all the reference layers are IRAP pictures may contain undesirable visual artefacts to the extent that decoded pictures in the current layer at and subsequent to the access unit containing the recovery point SEI message in decoding order should not be displayed until the specified recovery point in output order.
- Otherwise (`broken_link_flag` is equal to 0), no indication is given regarding any potential presence of visual artefacts.

When the current picture is a BLA picture, the value of `broken_link_flag` shall be equal to 1.

Regardless of the value of the `broken_link_flag`, pictures in the current layer subsequent to the specified recovery point in output order are specified to be correct or approximately correct in content.

F.14.3.2.5 Structure of pictures information SEI message semantics for multi-layer extensions

The specifications of clause D.3.19 apply by replacing the first paragraph specifying the persistence of the SEI message with the following:

The structure of pictures information SEI message provides information for a list of entries, some of which correspond to the target picture set consists of a series of pictures starting from the current picture until the last picture in decoding order in the current layer in the CLVS or the last picture in decoding order in the current POC resetting period, whichever is earlier.

F.14.3.2.6 Decoding unit information SEI message semantics for multi-layer extensions

The specifications of clause D.3.22 apply with the following modifications and additions:

When the decoding unit information SEI message is directly contained in a scalable nesting SEI message within an SEI NAL unit with a `nuh_layer_id` value `targetNuhLayerId` greater than 0, the semantics of clause D.3.22 apply to the output bitstream of the independent non-base layer rewriting process of clause F.10.2 with the input variables `assignedBaseLayerId` equal to `nestingLayerIdList[i][0]` and `tIdTarget` equal to `MaxTemporalId[i]` for each value of `i` in the range of 0 to `nestingNumOps - 1`, inclusive.

When the decoding unit information SEI message is contained in a bitstream partition nesting SEI message, the following applies:

- The variables `olsIdx`, `psIdx` and `bspIdx` are set equal to `sei_ols_idx`, `sei_partitioning_scheme_idx` and `bsp_idx`, respectively, of the bitstream partition nesting SEI message containing this buffering period SEI message, and the `bspIdx`-th bitstream partition of the `psIdx`-th partitioning scheme of the `olsIdx`-th OLS is referred to as the current bitstream partition.
- The variable `maxTId` is set equal to `MaxTemporalId[0]` for the scalable nesting SEI message containing the bitstream partition nesting SEI message containing this buffering period SEI message.
- The variable `hrdParamIdx` is set equal to the value of `bsp_hrd_idx[olsIdx][psIdx][maxTId][i][bspIdx]` for any value of `i` in the range of 0 to `BspSchedCnt[olsIdx][psIdx][maxTId] - 1`, inclusive.

- The following applies for the syntax and semantics of the decoding unit information SEI message:
 - The syntax elements `sub_pic_hrd_params_present_flag`, `sub_pic_cpb_params_in_pic_timing_sei_flag` and `dpb_output_delay_du_length_minus1`, and the variable `CpbDpbDelaysPresentFlag` are found in or derived from syntax elements in the `hrdParamIdx`-th `hrd_parameters()` syntax structure.
 - It is a requirement of bitstream conformance that the values of `sub_pic_hrd_params_present_flag`, `sub_pic_cpb_params_in_pic_timing_sei_flag` and `dpb_output_delay_du_length_minus1`, and `CpbDpbDelaysPresentFlag` derived using a particular value of `i` for the derivation of `hrdParamIdx` shall be the same as the value of the respective syntax elements or variable derived using any other allowed value of `i`.

The presence of decoding unit information SEI messages for the current bitstream partition is specified as follows on the basis of the syntax elements `sub_pic_hrd_params_present_flag` and `sub_pic_cpb_params_in_pic_timing_sei_flag` and the variable `CpbDpbDelaysPresentFlag` that are found or derived as specified above:

- If `CpbDpbDelaysPresentFlag` is equal to 1, `sub_pic_hrd_params_present_flag` is equal to 1 and `sub_pic_cpb_params_in_pic_timing_sei_flag` is equal to 0, one or more decoding unit information SEI messages applicable to the current bitstream partition shall be associated with each decoding unit of the current bitstream partition in the CVS.
- Otherwise, if `CpbDpbDelaysPresentFlag` is equal to 1, `sub_pic_hrd_params_present_flag` is equal to 1 and `sub_pic_cpb_params_in_pic_timing_sei_flag` is equal to 1, one or more decoding unit information SEI messages applicable to the current bitstream partition may or may not be associated with each decoding unit of the current bitstream partition in the CVS.
- Otherwise (`CpbDpbDelaysPresentFlag` is equal to 0 or `sub_pic_hrd_params_present_flag` is equal to 0), in the CVS there shall be no decoding unit of the current bitstream partition that is associated with a decoding unit information SEI message applicable to the current bitstream partition.

The set of NAL units associated with a decoding unit information SEI message contained in a bitstream partition nesting SEI message consists, in decoding order, of the SEI NAL unit containing the decoding unit information SEI message and all subsequent NAL units in the partition unit up to but not including any subsequent SEI NAL unit containing a decoding unit information SEI message that is contained in a bitstream partition nesting SEI message applying to the current bitstream partition and that has a different value of `decoding_unit_idx`.

It is a requirement of bitstream conformance that all decoding unit information SEI messages that are contained in a bitstream partition nesting SEI message, are associated with the same access unit, apply to the current bitstream partition and have `dpb_output_du_delay_present_flag` equal to 1 shall have the same value of `pic_spt_dpb_output_du_delay`.

F.14.3.2.7 Scalable nesting SEI message semantics for multi-layer extensions

The specifications of clause D.3.24 apply with the following modifications:

It is a requirement of bitstream conformance that the following restrictions apply on containing of SEI messages in a scalable nesting SEI message:

- An SEI message that has `payloadType` equal to 129 (active parameter sets), 132 (decoded picture hash), 133 (scalable nesting), 160 (layers not present), 163 (bitstream partition initial arrival time), 164 (sub-bitstream property) or 166 (overlay information) shall not be directly contained in a scalable nesting SEI message.
- When a scalable nesting SEI message contains a buffering period SEI message, a picture timing SEI message or a decoding unit information SEI message, the scalable nesting SEI message shall not contain any other SEI message with `payloadType` not equal to 0 (buffering period), 1 (picture timing) or 130 (decoding unit information).
- When present, an SEI message that has `payloadType` equal to 162 (bitstream partition nesting) shall be contained within a scalable nesting SEI message.
- When a scalable nesting SEI message contains a bitstream partition nesting SEI message, the scalable nesting SEI message shall not contain any other SEI message.

It is a requirement of bitstream conformance that the following restrictions apply on the value of `bitstream_subset_flag`:

- When the scalable nesting SEI message contains a buffering period SEI message, a picture timing SEI message, a decoding unit information SEI message or a bitstream partition nesting SEI message, `bitstream_subset_flag` shall be equal to 1.
- When the scalable nesting SEI message contains an SEI message that has `payloadType` equal to any value among `SingleLayerSeiList`, 161, 165, 167 or 168, `bitstream_subset_flag` shall be equal to 0.

When `nesting_op_idx[i]` is present, the list `nestingLayerIdList[i]` is set equal to `LayerSetLayerIdList[nesting_op_idx[i]]` derived from the active VPS.

When a scalable nesting SEI message contains a bitstream partition nesting SEI message, the following applies:

- nesting_op_flag shall be equal to 1, default_op_flag shall be equal to 0, nesting_num_ops_minus1 shall be equal to 0 and nesting_op_idx[0] shall not be equal to 0.
- The nuh_layer_id of the SEI NAL unit containing the scalable nesting SEI message shall be equal to the highest value within the list nestingLayerIdList[0].

When a scalable nesting SEI message directly contains a buffering period SEI message, a picture timing SEI message or a decoding unit information SEI message and the nuh_layer_id value of the SEI NAL unit containing the scalable nesting SEI message is greater than 0, it is a requirement of bitstream conformance that for any value of *i* in the range of default_op_flag to nesting_num_ops_minus1, inclusive, the nesting_op_idx[*i*]-th OLS consists of only the layer with nuh_layer_id equal to nestingLayerIdList[*i*][0], the profile of that layer is a profile specified in Annex A and the value of general_inbld_flag (when MaxTemporalId[*i*] is equal to vps_max_sub_layers_minus1) or the value of sub_layer_inbld_flag[tidTarget] (when MaxTemporalId[*i*] is less than vps_max_sub_layers_minus1) in the profile_tier_level() syntax structure associated with that layer is equal to 1.

NOTE – In other words, buffering period, picture timing, or decoding unit information SEI messages that are directly contained in an SEI NAL unit with nuh_layer_id greater than 0 can only be present for rewritable independent non-base layers.

F.14.3.2.8 Region refresh information SEI message semantics for multi-layer extensions

The region refresh information SEI message indicates whether the slice segments that the current SEI message applies to belong to a refreshed region of the current picture.

The variable targetLayerIdList is derived as follows:

- If the region refresh information SEI message applies to the current layer and all the reference layers, targetLayerIdList contains the nuh_layer_id of the current layer and all the reference layers.
- Otherwise, targetLayerIdList contains the nuh_layer_id of the current layer.

The region refresh SEI message is associated with a recovery point SEI message that applies to targetLayerIdList.

A picture that is not an IRAP picture, that belongs to a layer, and that is contained in an access unit containing a recovery point SEI message where the recovery point SEI message applies to that layer is referred to as a gradual decoding refresh (GDR) picture, and the access unit containing the picture is referred to as a GDR access unit. The access unit corresponding to the indicated recovery point picture is referred to as the recovery point access unit.

If there is a picture picB in the current layer that follows the GDR picture picA in the current layer in decoding order in the CVS and PicOrderCnt(picB) is equal to PicOrderCnt(picA) plus the value of recovery_poc_cnt in the recovery point SEI message, where PicOrderCnt(picA) and PicOrderCnt(picB) are the PicOrderCntVal values of picA and picB, respectively, immediately after the invocation of the decoding process for picture order count for picB, let the variable lastPicInSet be the recovery point picture. Otherwise, let lastPicInSet be the picture in targetLayerIdList that immediately precedes the recovery point picture in output order. The picture lastPicInSet shall not precede the GDR access unit in decoding order.

Let gdrPicSet be the set of pictures in targetLayerIdList starting from a GDR access unit to the access unit containing lastPicInSet, inclusive, in output order. When the decoding process for the current layer is started from a GDR access unit, the refreshed region in each picture of the gdrPicSet is indicated to be the region of the picture that is correct or approximately correct in content, and, when lastPicInSet is contained in the recovery point access unit, the refreshed region in lastPicInSet covers the entire picture.

The slice segments of the current picture to which a region refresh information SEI message applies consist of all slice segments within the picture that follow the SEI NAL unit containing the region refresh information SEI message and precede the next SEI NAL unit, in decoding order, containing a region refresh information SEI message (if any) that has the same targetLayerIdList as the current SEI message. These slice segments are referred to as the slice segments associated with the region refresh information SEI message.

Let gdrAuSet be the set of access units corresponding to gdrPicSet. A gdrAuSet and the corresponding gdrPicSet are referred to as being associated with the recovery point SEI message contained in the GDR access unit.

Region refresh information SEI messages shall not be present in an access unit unless the access unit is included in a gdrAuSet associated with a recovery point SEI message. When any picture that is included in a gdrPicSet is associated with one or more region refresh information SEI messages, all pictures in the gdrPicSet shall be associated with one or more region refresh information SEI messages.

refreshed_region_flag equal to 1 indicates that the slice segments associated with the current SEI message belong to the refreshed region in the current picture. refreshed_region_flag equal to 0 indicates that the slice segments associated with the current SEI message may not belong to the refreshed region in the current picture.

When one or more region refresh information SEI messages are associated with a picture belonging to `gdrPicSet` and the first slice segment of the picture in decoding order does not have an associated region refresh information SEI message, the value of `refreshed_region_flag` for the slice segments of the picture that precede the first region refresh information SEI message is inferred to be equal to 0.

When `lastPicInSet` is the recovery point picture, and any region refresh SEI message is associated with the recovery point access unit, the first slice segment of the picture in decoding order shall have an associated region refresh SEI message, and the value of `refreshed_region_flag` shall be equal to 1 in all region refresh SEI messages associated with the picture.

When one or more region refresh information SEI messages are associated with a picture, the refreshed region in the picture is specified as the set of CTUs in all slice segments of the picture that are associated with region refresh information SEI messages that have `refreshed_region_flag` equal to 1. Other slice segments belong to the non-refreshed region of the picture.

It is a requirement of bitstream conformance that when a dependent slice segment belongs to the refreshed region, the preceding slice segment in decoding order shall also belong to the refreshed region.

Let `gdrRefreshedSliceSegmentSet` be the set of all slice segments that belong to the refreshed regions in the `gdrPicSet`. The variable `upSwitchingRefreshedSliceSegmentSet` is derived as follows:

- If `targetLayerIdList` contains only one non-zero `nuh_layer_id`, `upSwitchingRefreshedSliceSegmentSet` is defined as the set inclusive of the following:
 - all slice segments of all pictures of the reference layers that precede, in decoding order, the current picture and that may be used for reference by the current picture or subsequent pictures of the reference layers.
 - all slice segments of all pictures of the reference layers that succeed, in decoding order, the current picture and that belong to `gdrAuSet`.
- Otherwise, `upSwitchingRefreshedSliceSegmentSet` is defined as an empty set.

When a `gdrPicSet` contains one or more pictures associated with region refresh information SEI messages, it is a requirement of bitstream conformance that the following constraints all apply:

- For each layer in `targetLayerIdList`, the refreshed region in the first picture, in decoding order, that belongs to the layer and that is included in `gdrPicSet` that contains any refreshed region shall contain only coding units that are coded in an intra coding mode or inter-layer prediction from slice segments belonging to the union of `gdrRefreshedSliceSegmentSet` and `upSwitchingRefreshedSliceSegmentSet`.
- For each picture included in the `gdrPicSet`, the syntax elements in `gdrRefreshedSliceSegmentSet` shall be constrained such that no samples or motion vector values outside of the union of `gdrRefreshedSliceSegmentSet` and `upSwitchingRefreshedSliceSegmentSet` are used for inter prediction or inter-layer prediction in the decoding process of any samples within `gdrRefreshedSliceSegmentSet`.
- For any picture that follows the picture `lastPicInSet` in output order, the syntax elements in the slice segments of the picture shall be constrained such that no samples or motion vector values outside of the union of `gdrRefreshedSliceSegmentSet` and `upSwitchingRefreshedSliceSegmentSet` are used for inter prediction or inter-layer prediction in the decoding process of the picture other than those of the other pictures that follow the picture `lastPicInSet` in output order.

F.14.3.2.9 Coded region completion SEI message semantics for multi-layer extensions

The specifications of clause D.3.37 apply with the following additions:

The `nuh_layer_id` value of the SEI NAL unit containing a coded region completion SEI message shall be equal to the `nuh_layer_id` value of the associated VCL NAL unit for the SEI NAL unit.

When an access unit contains one or more layers not present SEI messages, any coded region completion SEI message with `next_segment_address` equal to 0 in that access unit shall follow the first layers not present SEI message, in decoding order, that is present in that access unit.

NOTE – The specifications given in clause F.7.4.2.4.4 for associating NAL units to access units facilitate determining of an end of an access unit when the first NAL unit of the next access unit is available. Some implementations may operate on access unit basis, e.g. when inputting NAL units to a decoder. The latency in such implementations is potentially reduced, when a bitstream includes multiple layers and an end of an access unit for the OLS with index `trgtOlsIdx` is concluded as follows in response to decoding a coded region completion SEI message with `next_segment_address` equal to 0:

- The variable `layerMayBePresent[layerIdx]` is derived as follows:
 - If a layers not present SEI message is present in the current CVS and precedes the coded region completion SEI message in decoding order, `layerMayBePresentFlag[layerIdx]` is set equal to `!layer_not_present_flag[layerIdx]` of the previous layers not present SEI message, in decoding order, for each value of `layerIdx` from 0 to `MaxLayersMinus1`, inclusive.
 - Otherwise, `layerMayBePresentFlag[layerIdx]` is set equal to 1 for each value of `layerIdx` from 0 to `MaxLayersMinus1`, inclusive.

- Let a set of `nuh_layer_id` values `trgtLayerIdList` of the necessary layers for an OLS with index `trgtOlsIdx` be equal to `TargetDecLayerIdList` derived using Equation F-57 by setting `TargetOlsIdx` equal to `trgtOlsIdx`.
- Let `numTrgtLayerIds` be equal to the number of `nuh_layer_id` values in `trgtLayerIdList`.
- Let `currLayerId` be equal to the `nuh_layer_id` value of the VCL NAL unit associated with the SEI NAL unit containing this coded region completion SEI message.
- Let `prevNecessaryLayerTrgtIdx` be the index of the greatest value within `trgtLayerIdList` that is less than or equal to `currLayerId`.
- When one of the following is true, there are no VCL NAL units of any necessary layer of the OLS with index `trgtOlsIdx` following, in decoding order, the VCL NAL unit associated with the SEI NAL unit containing this SEI message within the current access unit:
 - `currLayerId` is greater than or equal to any value in `trgtLayerIdList`.
 - `layerMayBePresentFlag[LayerIdxInVps[layerId]]` is equal to 0 for all the values of `layerId` equal to `trgtLayerIdList[trgtIdx]` for each `trgtIdx` in the range of `prevNecessaryLayerTrgtIdx + 1` to `numTrgtLayerIds - 1`, inclusive.

F.14.3.3 Layers not present SEI message semantics

The layers not present SEI message provides a mechanism for signalling that VCL NAL units of particular layers indicated by the VPS are not present in a particular set of access units.

The target access units are defined as the set of access units starting from the access unit containing the layers not present SEI message up to but not including the next access unit, in decoding order, that contains a layers not present SEI message or the end of the CVS, whichever is earlier in decoding order.

When present, the layers not present SEI message applies to the target access units.

When a layers not present SEI message is associated with a coded picture with TemporalId `firstTid` that is greater than 0 and that coded picture is followed, in decoding order, by any coded picture with TemporalId less than `firstTid` in the same CVS, a layers not present SEI message shall be present for the next coded picture, in decoding order, with TemporalId less than `firstTid`.

lnp_sei_active_vps_id identifies the active VPS of the CVS containing the layers not present SEI message. The value of **lnp_sei_active_vps_id** shall be equal to the value of **vps_video_parameter_set_id** of the active VPS for the VCL NAL units of the access unit containing the SEI message.

layer_not_present_flag[i] equal to 1 indicates that there are no VCL NAL units with `nuh_layer_id` equal to `layer_id_in_nuh[i]` present in the target access units. **layer_not_present_flag[i]** equal to 0 indicates that there may or may not be VCL NAL units with `nuh_layer_id` equal to `layer_id_in_nuh[i]` present in the target access units.

When **layer_not_present_flag[i]** is equal to 1 and `i` is less than `MaxLayersMinus1`, **layer_not_present_flag[LayerIdxInVps[IdPredictedLayer[layer_id_in_nuh[i]][j]]]** shall be equal to 1 for all values of `j` in the range of 0 to `NumPredictedLayers[layer_id_in_nuh[i]] - 1`, inclusive.

F.14.3.4 Inter-layer constrained tile sets SEI message semantics

The scope of the inter-layer constrained tile sets SEI message is a complete CLVS of the layer with `nuh_layer_id` equal to `targetLayerId`. When an inter-layer constrained tile sets SEI message is present for any coded picture of a CLVS and the first coded picture of the CLVS in decoding order is an IRAP picture, the inter-layer constrained tile sets SEI message shall be present for the first coded picture of the CLVS in decoding order and may also be present for other coded pictures of the CLVS.

The inter-layer constrained tile sets SEI message shall not be present for the layer with `nuh_layer_id` equal to `targetLayerId` when **tiles_enabled_flag** is equal to 0 for any PPS that is active for the pictures of the CLVS of the layer with `nuh_layer_id` equal to `targetLayerId`.

The inter-layer constrained tile sets SEI message shall not be present for the layer with `nuh_layer_id` equal to `targetLayerId` unless every PPS that is active for the pictures of the CLVS of the layer with `nuh_layer_id` equal to `targetLayerId` has **tile_boundaries_aligned_flag** equal to 1 or fulfills the conditions that would be indicated by **tile_boundaries_aligned_flag** being equal to 1.

An identified tile set is defined as a set of tiles within a picture with `nuh_layer_id` equal to `targetLayerId` that contains the tiles specified below on the basis of the values of the syntax elements contained in the inter-layer constrained tile sets SEI message.

An associated reference tile set for the `iPred`-th identified tile set with **ilcts_id[iPred]** equal to `ilctsId`, if any, is defined as the identified tile set present in the same access unit as the `iPred`-th identified tile set and associated with **ilcts_id[iRef]** equal to `ilctsId` and `nuh_layer_id` equal to `IdDirectRefLayer[targetLayerId][j]` for any value of `j` in the range of 0 to `NumDirectRefLayers[targetLayerId] - 1`, inclusive.

The presence of the inter-layer constrained tile sets SEI message indicates that the inter-layer prediction process is constrained such that no sample value outside each associated reference tile set, and no sample value at a fractional sample position that is derived using one or more sample values outside each associated reference tile set, is used for inter-layer prediction of any sample within the identified tile set.

NOTE 1 – When loop filtering and resampling filter are applied across tile boundaries, inter-layer prediction of any samples within an identified tile set that refers to samples within 8 samples from an associated reference tile set boundary that is not also a picture boundary may result in propagation of mismatch error. An encoder can avoid such potential error propagation by avoiding the use of motion vectors that cause such references.

When more than one inter-layer constrained tile sets SEI message is present for a CLVS, they shall contain identical content.

The number of inter-layer constrained tile sets SEI messages for the same CLVS in each access unit shall not exceed 5.

il_all_tiles_exact_sample_value_match_flag equal to 1 indicates that, within the CLVS, when the CTBs that are outside of any tile in any identified tile set specified in this inter-layer constrained tile sets SEI message are not decoded and the boundaries of the tile is treated as picture boundaries for purposes of the decoding process, the value of each sample in the tile would be exactly the same as the value of the sample that would be obtained when all the CTBs of all pictures in the CLVS are decoded. **il_all_tiles_exact_sample_value_match_flag** equal to 0 indicates that, within the CLVS, when the CTBs that are outside of any tile in any identified tile set specified in this inter-layer constrained tile sets SEI message are not decoded and the boundaries of the tile is treated as picture boundaries for purposes of the decoding process, the value of each sample in the tile may or may not be exactly the same as the value of the same sample when all the CTBs of all pictures in the CLVS are decoded.

il_one_tile_per_tile_set_flag equal to 1 indicates that each identified tile set contains one tile and **il_num_sets_in_message_minus1** is not present.

It is a requirement of bitstream conformance that when **il_one_tile_per_tile_set_flag** is equal to 1, the value of $(\text{num_tile_columns_minus1} + 1) * (\text{num_tile_rows_minus1} + 1)$ shall be less than or equal to 256.

When **il_one_tile_per_tile_set_flag** is equal to 0, the identified tile sets are signalled explicitly.

il_num_sets_in_message_minus1 plus 1 specifies the number of the identified tile sets in the SEI message. The value of **il_num_sets_in_message_minus1** shall be in the range of 0 to 255, inclusive.

skipped_tile_set_present_flag equal to 1 indicates that, within the CLVS, the **il_num_sets_in_message_minus1**-th identified tile set consists of those remaining tiles that are not included in any earlier identified tile sets in the same message and all the prediction blocks that are inside the **il_num_sets_in_message_minus1**-th identified tile set are inter-layer predicted from inter-layer reference pictures with **nuh_layer_id** equal to **IdDirectRefLayer[targetLayerId][NumDirectRefLayers[targetLayerId] - 1]** and no residual coding() syntax structure is present in any transform unit of the **il_num_sets_in_message_minus1**-th identified tile set. **skipped_tile_set_present_flag** equal to 0 does not indicate a bitstream constraint within the CLVS. When not present, the value of **skipped_tile_set_present_flag** is inferred to be equal to 0.

ilcts_id[i] contains an identifying number that may be used to identify the purpose of the i-th identified tile set (for example, to identify an area to be extracted from the coded video sequence for a particular purpose). The value of **ilcts_id[i]** shall be in the range of 0 to $2^{32} - 2$, inclusive.

Values of **ilcts_id[i]** from 0 to 255, inclusive, and from $2^{31} - 1$, inclusive, may be used as determined by the application. If **il_one_tile_per_tile_set_flag** is equal to 1, values of **ilcts_id[i]** from 256 to 511, inclusive, are used for the inferred **ilcts_id[i]** values as specified above. Otherwise, values of **ilcts_id[i]** from 256 to 511, inclusive, are reserved for future use by ITU-T | ISO/IEC. Values of **ilcts_id[i]** from 2^{31} to $2^{32} - 2$, inclusive, are reserved for future use by ITU-T | ISO/IEC. Decoders encountering an indicated value of **ilcts_id[i]** in the range of 256 to 511, inclusive, or in the range of 2^{31} to $2^{32} - 2$, inclusive, shall ignore it.

When **ilcts_id[i]** is not present for i in the range of 0 to $(\text{num_tile_columns_minus1} + 1) * (\text{num_tile_rows_minus1} + 1) - 1$, inclusive, due to **il_one_tile_per_tile_set_flag** being equal to 1, it is inferred to be equal to $256 + i$.

il_num_tile_rects_in_set_minus1[i] plus 1 specifies the number of rectangular regions of tiles in the i-th identified tile set. The value of **il_num_tile_rects_in_set_minus1[i]** shall be in the range of 0 to $(\text{num_tile_columns_minus1} + 1) * (\text{num_tile_rows_minus1} + 1) - 1$, inclusive.

il_top_left_tile_idx[i][j] and **il_bottom_right_tile_idx[i][j]** identify the tile position of the top-left tile and the tile position of the bottom-right tile in a rectangular region of the i-th identified tile set, respectively, in tile raster scan order.

ilc_idc[i] equal to 1 indicates that no samples outside of any associated reference tile set and no samples at a fractional sample position that is derived using one or more samples outside of any associated reference tile set are used for inter-layer prediction of any sample within the i-th identified tile set. **ilc_idc[i]** equal to 2 indicates that no prediction block in

the *i*-th identified tile set is predicted from an inter-layer reference picture. *ilc_idc*[*i*] equal to 0 indicates that the inter-layer prediction process may or may not be constrained for the prediction block in the *i*-th identified tile set. The value of *ilc_idc*[*i*] equal to 3 is reserved.

il_exact_sample_value_match_flag[*i*] equal to 1 indicates that, within the CLVS, when the CTBs that do not belong to the *i*-th identified tile set are not decoded and the boundaries of the *i*-th identified tile set are treated as picture boundaries for the purposes of the decoding process, the value of each sample in the *i*-th identified tile set would be exactly the same as the value of the sample that would be obtained when all the CTBs of all pictures in the CLVS are decoded. **il_exact_sample_value_match_flag**[*i*] equal to 0 indicates that, within the CLVS, when the CTBs that are outside of the *i*-th identified tile set are not decoded and the boundaries of the *i*-th identified tile set are treated as picture boundaries for the purposes of the decoding process, the value of each sample in the *i*-th identified tile set may or may not be exactly the same as the value of the same sample when all the CTBs of all pictures in the CLVS are decoded.

NOTE 2 – It is feasible to use **il_exact_sample_value_match_flag** equal to 1 when using certain combinations of **loop_filter_across_tiles_enabled_flag**, **pps_loop_filter_across_slices_enabled_flag**, **pps_deblocking_filter_disabled_flag**, **slice_loop_filter_across_slices_enabled_flag**, **slice_deblocking_filter_disabled_flag**, **sample_adaptive_offset_enabled_flag**, **slice_sao_luma_flag** and **slice_sao_chroma_flag**.

all_tiles_ilc_idc equal to 1 indicates that, for each identified tile set within the CLVS, no sample value outside of each associated reference tile set and no sample value at a fractional sample position that is derived using one or more samples outside of each associated reference tile set is used for inter-layer prediction of any sample within the identified tile set. **all_tiles_ilc_idc** equal to 2 indicates that, within the CLVS, no prediction block in each identified tile set is predicted from an inter-layer reference picture. **all_tiles_ilc_idc** equal to 0 indicates that, within the CLVS, the inter-layer prediction process may or may not be constrained for the identified tile sets. The value of **all_tiles_ilc_idc** equal to 3 is reserved. When **all_tiles_ilc_idc** is not present, it is inferred to be equal to 0.

F.14.3.5 Bitstream partition nesting SEI message semantics

The bitstream partition nesting SEI message provides a mechanism to associate SEI messages with a bitstream partition of a partitioning scheme of an OLS.

NOTE – The bitstream partition nesting SEI message must be contained within a scalable nesting SEI message. Constraints on the scalable nesting SEI message containing a bitstream partition nesting SEI message are specified in clause F.14.3.2.7.

A bitstream partition nesting SEI message contains one or more SEI messages.

sei_ols_idx specifies the index of the OLS to which the contained SEI messages apply. The value of **sei_ols_idx** shall be in the range of 0 to **NumOutputLayerSets** – 1, inclusive.

It is a requirement of bitstream conformance that **OlsIdxToLsIdx**[**sei_ols_idx**] shall be equal to **nesting_op_idx**[0] of the scalable nesting SEI message that contains the bitstream partition nesting SEI message.

sei_partitioning_scheme_idx specifies the index of the partitioning scheme to which the contained SEI messages apply. The value of **sei_partitioning_scheme_idx** shall be in the range of 0 to **num_signalled_partitioning_schemes**[**sei_ols_idx**], inclusive.

bsp_idx specifies the index of the bitstream partition to which the contained SEI messages apply. The value of **bsp_idx** shall be in the range of 0 to **num_partitions_in_scheme_minus1**[**sei_ols_idx**][**sei_partitioning_scheme_idx**], inclusive.

num_seis_in_bsp_minus1 plus 1 specifies the number of **sei_message**() syntax structures contained in the **bsp_nesting**() syntax structure. The value of **num_seis_in_bsp_minus1** shall be in the range of 0 to 63, inclusive.

bsp_nesting_zero_bit shall be equal to 0.

F.14.3.6 Bitstream partition initial arrival time SEI message semantics

The bitstream partition initial arrival time SEI message specifies the initial arrival times to be used in the bitstream-partition-specific CPB operation.

When present, this SEI message shall be contained within a bitstream partition nesting SEI message that is contained in a scalable nesting SEI message, and the same bitstream partition nesting SEI message shall also contain a buffering period SEI message.

The following applies for each value of *i* in the range of 0 to **BspSchedCnt**[**olsIdx**][**psIdx**][**MaxTemporalId**[0]] – 1, inclusive:

- The variable **hrdParamIdx**[*i*] is set equal to the value of **bsp_hrd_idx**[**olsIdx**][**psIdx**][**maxTemporalId**[0]][*i*][**bspIdx**], where **olsIdx**, **psIdx** and **bspIdx** are equal to **sei_ols_idx**, **sei_partitioning_scheme_idx** and **bsp_idx**, respectively, of the bitstream partition nesting SEI message containing this bitstream partition initial arrival time SEI message, and **maxTemporalId**[0] is the value of

MaxTemporalId[0] for the scalable nesting SEI message containing the bitstream partition nesting SEI message containing this bitstream partition initial arrival time SEI message.

- The variable initialCpbRemovalDelayLength[i] is set equal to initial_cpb_removal_delay_length_minus1 + 1, where initial_cpb_removal_delay_length_minus1 is found in the hrdParamIdx[i]-th hrd_parameters() syntax structure in the active VPS.
- The variable nalHrdParamsPresent[i] is set equal to the value of nal_hrd_parameters_present_flag in the hrdParamIdx[i]-th hrd_parameters() syntax structure in the active VPS.
- The variable vclHrdParamsPresent[i] is set equal to the value of vcl_hrd_parameters_present_flag in the hrdParamIdx[i]-th hrd_parameters() syntax structure in the active VPS.

It is a requirement of bitstream conformance that the value of nalHrdParamsPresent[i] shall be the same for all values of i in the range of 0 to BspSchedCnt[olsIdx][psIdx][MaxTemporalId[0]] – 1, inclusive.

It is a requirement of bitstream conformance that the value of vclHrdParamsPresent[i] shall be the same for all values of i in the range of 0 to BspSchedCnt[olsIdx][psIdx][MaxTemporalId[0]] – 1, inclusive.

The variable nalInitialArrivalDelayPresent is set equal to nalHrdParamsPresent[i] of any value of i in the range of 0 to BspSchedCnt[olsIdx][psIdx][MaxTemporalId[0]] – 1, inclusive.

The variable vclInitialArrivalDelayPresent is set equal to vclHrdParamsPresent[i] of any value of i in the range of 0 to BspSchedCnt[olsIdx][psIdx][MaxTemporalId[0]] – 1, inclusive.

nal_initial_arrival_delay[i] specifies the initial arrival time for the i-th delivery schedule of the bitstream partition to which this SEI message applies, when NAL HRD parameters are in use. The length, in bits, of the nal_initial_arrival_delay[i] syntax element is equal to initialCpbRemovalDelayLength[i].

vcl_initial_arrival_delay[i] specifies the initial arrival time for the i-th delivery schedule of the bitstream partition to which this SEI message applies, when VCL HRD parameters are in use. The length, in bits, of the vcl_initial_arrival_delay[i] syntax element is equal to initialCpbRemovalDelayLength[i].

F.14.3.7 Sub-bitstream property SEI message semantics

The sub-bitstream property SEI message, when present, provides the bit rate information for a sub-bitstream created by discarding those pictures in the layers that do not belong to the output layers of the OLSs specified by the active VPS and that do not affect the decoding of the output layers.

When present, the sub-bitstream property SEI message shall be associated with an initial IRAP access unit and the information provided by the SEI messages applies to the bitstream corresponding to the CVS containing the associated initial IRAP access unit.

sb_property_active_vps_id identifies the active VPS. The value of sb_property_active_vps_id shall be equal to the value of vps_video_parameter_set_id of the active VPS referred to by the VCL NAL units of the associated access unit.

num_additional_sub_streams_minus1 plus 1 specifies the number of the sub-bitstreams for which the bit rate information may be provided by this SEI message. The value of num_additional_sub_streams_minus1 shall be in the range of 0 to $2^{10} - 1$, inclusive.

sub_bitstream_mode[i] specifies how the i-th sub-bitstream is generated. The value of sub_bitstream_mode[i] shall be equal to 0 or 1, inclusive. The values 2 and 3 are reserved for future use by ITU-T and ISO/IEC. When sub_bitstream_mode[i] is the greater than 1, decoders shall ignore the syntax elements ols_idx_to_vps[i], highest_sublayer_id[i], avg_sb_property_bit_rate[i] and max_sb_property_bit_rate[i].

When sub_bitstream_mode[i] is equal to 0, the i-th sub-bitstream is generated as follows:

- Let lsIdx be equal to OlsIdxToLsIdx[ols_idx_to_vps[i]].
- A sub-bitstream subBitstream[i] is first created as follows:
 - If lsIdx is less than or equal to vps_num_layer_sets_minus1 and vps_base_layer_internal_flag is equal to 1, the sub-bitstream extraction process as specified in clause 10 is invoked with the bitstream corresponding to the CVS containing the sub-bitstream property SEI message, highest_sublayer_id[i] and LayerSetLayerIdList[lsIdx] as inputs, and the output is assigned to subBitstream[i].
 - Otherwise, if lsIdx is less than or equal to vps_num_layer_sets_minus1 and vps_base_layer_internal_flag is equal to 0, the sub-bitstream extraction process as specified in clause F.10.1 is invoked with the bitstream corresponding to the CVS containing the sub-bitstream property SEI message, highest_sublayer_id[i] and LayerSetLayerIdList[lsIdx] as inputs, and the output is assigned to subBitstream[i].

- Otherwise, the sub-bitstream extraction process as specified in clause F.10.3 is invoked with the bitstream corresponding to the CVS containing the sub-bitstream property SEI message, `highest_sublayer_id[i]` and `LayerSetLayerIdList[lIdx]` as inputs, and the output is assigned to `subBitstream[i]`.
- Remove all NAL units for which the `nuh_layer_id` is not included in `TargetOptLayerIdList` and either of the following conditions is true:
 - The value of `nal_unit_type` is not in the range of `BLA_W_LP` to `RSV_IRAP_VCL23`, inclusive, and `max_tid_il_ref_pics_plus1[LayerIdxInVps[nuh_layer_id]][LayerIdxInVps[layerId]]` is equal to 0 for `layerId` values included in `TargetOptLayerIdList`.
 - `TemporalId` is greater than the maximum value of `max_tid_il_ref_pics_plus1[LayerIdxInVps[nuh_layer_id]][LayerIdxInVps[layerId]] - 1` for all `layerId` values included in `TargetOptLayerIdList`.

When `sub_bitstream_mode[i]` is equal to 1, the *i*-th sub-bitstream is generated as specified by the above process followed by:

- Remove all NAL units with `nuh_layer_id` not among the values included in `TargetOptLayerIdList` and with `discardable_flag` equal to 1.

`ols_idx_to_vps[i]` specifies the index of the OLS corresponding to the *i*-th sub-bitstream. The value of `ols_idx_to_vps[i]` shall be in the range of 0 to `NumOutputLayerSets - 1`, inclusive.

`highest_sublayer_id[i]` specifies the highest `TemporalId` of access units in the *i*-th sub-bitstream.

`avg_sb_property_bit_rate[i]` indicates the average bit rate of the *i*-th sub-bitstream, in bits per second. The value is given by `BitRateBPS(avg_sb_property_bit_rate[i])` with the function `BitRateBPS()` being specified as follows:

$$\text{BitRateBPS}(x) = (x \& (2^{14} - 1)) * 10^{(2 + (x \gg 14))} \quad (\text{F-91})$$

The average bit rate is derived according to the access unit removal time specified in clause F.13. In the following, `bTotal` is the number of bits in all NAL units of the *i*-th sub-bitstream, `t1` is the removal time (in seconds) of the first access unit to which the VPS applies and `t2` is the removal time (in seconds) of the last access unit (in decoding order) to which the VPS applies. With `x` specifying the value of `avg_sb_property_bit_rate[i]`, the following applies:

- If `t1` is not equal to `t2`, the following condition shall be true:

$$(x \& (2^{14} - 1)) == \text{Round}(bTotal \div ((t_2 - t_1) * 10^{(2 + (x \gg 14))})) \quad (\text{F-92})$$

- Otherwise (`t1` is equal to `t2`), the following condition shall be true:

$$(x \& (2^{14} - 1)) == 0 \quad (\text{F-93})$$

`max_sb_property_bit_rate[i]` indicates an upper bound for the bit rate of the *i*-th sub-bitstream in any one-second time window of access unit removal time as specified in clause F.13. The upper bound for the bit rate in bits per second is given by `BitRateBPS(max_sb_property_bit_rate[i])`. The bit rate values are derived according to the access unit removal time specified in clause F.13. In the following, `t1` is any point in time (in seconds), `t2` is set equal to `t1 + 1 ÷ 100` and `bTotal` is the number of bits in all NAL units of access units with a removal time greater than or equal to `t1` and less than `t2`. With `x` specifying the value of `max_sb_property_bit_rate[i]`, the following condition shall be obeyed for all values of `t1`:

$$(x \& (2^{14} - 1)) \geq bTotal \div ((t_2 - t_1) * 10^{(2 + (x \gg 14))}) \quad (\text{F-94})$$

F.14.3.8 Alpha channel information SEI message semantics

The alpha channel information SEI message provides information about alpha channel sample values and post-processing applied to the decoded alpha planes coded in auxiliary pictures of type `AUX_ALPHA` and one or more associated primary pictures.

For an auxiliary picture with `nuh_layer_id` equal to `nuhLayerIdA` and `AuxId[nuhLayerIdA]` equal to `AUX_ALPHA`, an associated primary picture, if any, is a picture in the same access unit having `AuxId[nuhLayerIdB]` equal to 0 such that `ScalabilityId[LayerIdxInVps[nuhLayerIdA]][j]` is equal to `ScalabilityId[LayerIdxInVps[nuhLayerIdB]][j]` for all values of `j` in the range of 0 to 2, inclusive, and 4 to 15, inclusive.

When an access unit contains an auxiliary picture `picA` with `nuh_layer_id` equal to `nuhLayerIdA` and `AuxId[nuhLayerIdA]` equal to `AUX_ALPHA`, the alpha channel sample values of `picA` persist in output order until one or more of the following conditions are true:

- The next picture, in output order, with `nuh_layer_id` equal to `nuhLayerIdA` is output.
- A CLVS containing the auxiliary picture `picA` ends.
- The bitstream ends.

- A CLVS of any associated primary layer of the auxiliary picture layer with `nuh_layer_id` equal to `nuhLayerIdA` ends.

The following semantics apply separately to each `nuh_layer_id` `targetLayerId` among the `nuh_layer_id` values to which the alpha channel information SEI message applies.

alpha_channel_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous alpha channel information SEI message in output order that applies to the current layer. `alpha_channel_cancel_flag` equal to 0 indicates that alpha channel information follows.

Let `currPic` be the picture that the alpha channel information SEI message is associated with. The semantics of alpha channel information SEI message persist for the current layer in output order until one or more of the following conditions are true:

- A new CLVS of the current layer begins.
- The bitstream ends.
- A picture `picB` with `nuh_layer_id` equal to `targetLayerId` in an access unit containing an alpha channel information SEI message with `nuh_layer_id` equal to `targetLayerId` is output having `PicOrderCnt(picB)` greater than `PicOrderCnt(currPic)`, where `PicOrderCnt(picB)` and `PicOrderCnt(currPic)` are the `PicOrderCntVal` values of `picB` and `currPic`, respectively, immediately after the invocation of the decoding process for picture order count for `picB`.

alpha_channel_use_idc equal to 0 indicates that for alpha blending purposes the decoded samples of the associated primary picture should be multiplied by the interpretation sample values of the auxiliary coded picture in the display process after output from the decoding process. `alpha_channel_use_idc` equal to 1 indicates that for alpha blending purposes the decoded samples of the associated primary picture should not be multiplied by the interpretation sample values of the auxiliary coded picture in the display process after output from the decoding process. `alpha_channel_use_idc` equal to 2 indicates that the usage of the auxiliary picture is unspecified. Values greater than 2 for `alpha_channel_use_idc` are reserved for future use by ITU-T | ISO/IEC. When not present, the value of `alpha_channel_use_idc` is inferred to be equal to 2.

alpha_channel_bit_depth_minus8 plus 8 specifies the bit depth of the samples of the luma sample array of the auxiliary picture. `alpha_channel_bit_depth_minus8` shall be in the range 0 to 7 inclusive. `alpha_channel_bit_depth_minus8` shall be equal to `bit_depth_luma_minus8` of the associated primary picture.

alpha_transparent_value specifies the interpretation sample value of an auxiliary coded picture luma sample for which the associated luma and chroma samples of the primary coded picture are considered transparent for purposes of alpha blending. The number of bits used for the representation of the `alpha_transparent_value` syntax element is `alpha_channel_bit_depth_minus8 + 9`.

alpha_opaque_value specifies the interpretation sample value of an auxiliary coded picture luma sample for which the associated luma and chroma samples of the primary coded picture are considered opaque for purposes of alpha blending. The number of bits used for the representation of the `alpha_opaque_value` syntax element is `alpha_channel_bit_depth_minus8 + 9`.

alpha_channel_incr_flag equal to 0 indicates that the interpretation sample value for each decoded auxiliary picture luma sample value is equal to the decoded auxiliary picture sample value for purposes of alpha blending. `alpha_channel_incr_flag` equal to 1 indicates that, for purposes of alpha blending, after decoding the auxiliary picture samples, any auxiliary picture luma sample value that is greater than $\text{Min}(\text{alpha_opaque_value}, \text{alpha_transparent_value})$ should be increased by one to obtain the interpretation sample value for the auxiliary picture sample and any auxiliary picture luma sample value that is less than or equal to $\text{Min}(\text{alpha_opaque_value}, \text{alpha_transparent_value})$ should be used, without alteration, as the interpretation sample value for the decoded auxiliary picture sample value. When not present, the value of `alpha_channel_incr_flag` is inferred to be equal to 0.

alpha_channel_clip_flag equal to 0 indicates that no clipping operation is applied to obtain the interpretation sample values of the decoded auxiliary picture. `alpha_channel_clip_flag` equal to 1 indicates that the interpretation sample values of the decoded auxiliary picture are altered according to the clipping process described by the `alpha_channel_clip_type_flag` syntax element. When not present, the value of `alpha_channel_clip_flag` is inferred to be equal to 0.

alpha_channel_clip_type_flag equal to 0 indicates that, for purposes of alpha blending, after decoding the auxiliary picture samples, any auxiliary picture luma sample that is greater than $(\text{alpha_opaque_value} - \text{alpha_transparent_value}) / 2$ is set equal to `alpha_opaque_value` to obtain the interpretation sample value for the auxiliary picture luma sample and any auxiliary picture luma sample that is less or equal than $(\text{alpha_opaque_value} - \text{alpha_transparent_value}) / 2$ is set equal to `alpha_transparent_value` to obtain the interpretation sample value for the auxiliary picture luma sample. `alpha_channel_clip_type_flag` equal to 1 indicates that, for purposes of alpha blending, after decoding the auxiliary picture samples, any auxiliary picture luma sample that is greater than `alpha_opaque_value` is set equal to `alpha_opaque_value` to obtain the interpretation sample value for the auxiliary picture luma sample and any auxiliary picture luma sample that is less than or equal to `alpha_transparent_value` is set equal to

alpha_transparent_value to obtain the interpretation sample value for the auxiliary picture luma sample.

NOTE – When both alpha_channel_incr_flag and alpha_channel_clip_flag are equal to one, the clipping operation specified by alpha_channel_clip_type_flag should be applied first followed by the alteration specified by alpha_channel_incr_flag to obtain the interpretation sample value for the auxiliary picture luma sample.

F.14.3.9 Overlay information SEI message semantics

The overlay information SEI message provides information about overlay pictures coded as auxiliary pictures. Overlay auxiliary pictures have nuh_layer_id equal to nuhLayerIdA and AuxId[nuhLayerIdA] in the range of 128 to 159, inclusive. Each overlay auxiliary picture layer is associated with one or more primary picture layers as specified below.

overlay_info_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous overlay information SEI message in output order that is associated with one or more primary picture layers to which this SEI applies. overlay_info_cancel_flag equal to 0 indicates that overlay information follows.

overlay_content_aux_id_minus128 plus 128 indicates the value of AuxId of auxiliary pictures containing overlay content. overlay_content_aux_id_minus128 shall be in the range of 0 to 31, inclusive.

overlay_label_aux_id_minus128 plus 128 indicates the value of AuxId of auxiliary pictures containing overlay label. overlay_label_aux_id_minus128 shall be in the range of 0 to 31, inclusive.

overlay_alpha_aux_id_minus128 plus 128 indicates the value of AuxId of auxiliary pictures containing overlay alpha. overlay_alpha_aux_id_minus128 shall be in the range of 0 to 31, inclusive.

overlay_element_label_value_length_minus8 plus 8 indicates the number of bits used for coding the overlay_element_label_min[i][j] and overlay_element_label_max[i][j] syntax elements.

num_overlays_minus1 plus 1 specifies the number of overlays described by the overlay information SEI message. num_overlays_minus1 shall be in the range of 0 to 15, inclusive.

overlay_idx[i] indicates the index of the i-th overlay. overlay_idx[i] shall be in the range of 0 to 255, inclusive.

language_overlay_present_flag[i] equal to 1 indicates that overlay_language[i] is present. language_overlay_present_flag[i] equal to 0 indicates that overlay_language[i] is not present and that the language of the overlay is unspecified.

overlay_content_layer_id[i] indicates the nuh_layer_id value of the NAL units of the overlay content of the i-th overlay. AuxId[overlay_content_layer_id[i]] shall be equal to overlay_content_aux_id_minus128 + 128 for all values of i in the range of 0 to num_overlays_minus1, inclusive.

The value of the variable pLid, which identifies the nuh_layer_id value of the primary picture which the i-th overlay is associated with, is derived as follows:

```
pLid = -1
for( j = 0; j < 63; j++ )
    if( ViewOrderIdx[ j ] == ViewOrderIdx[ overlay_content_layer_id[ i ] ] &&
        DependencyId[ j ] == DependencyId[ overlay_content_layer_id[ i ] ] && AuxId[ j ] ==
0 )
        pLid = j
```

The value of pLid shall be in the range of 0 to 62, inclusive.

overlay_label_present_flag[i] equal to 1 specifies that overlay_label_layer_id[i] is present. overlay_label_present_flag[i] equal to 0 specifies that overlay_label_layer_id[i] is not present.

overlay_label_layer_id[i] indicates the nuh_layer_id value of NAL units in the overlay label of the i-th overlay. AuxId[overlay_label_layer_id[i]] shall be equal to overlay_label_aux_id_minus128 + 128 for all values of i in the range of 0 to num_overlays_minus1, inclusive.

overlay_alpha_present_flag[i] equal to 1 specifies that overlay_alpha_layer_id[i] is present. overlay_alpha_present_flag[i] equal to 0 specifies that overlay_alpha_layer_id[i] is not present.

overlay_alpha_layer_id[i] indicates the nuh_layer_id value of NAL units in the overlay alpha of the i-th overlay. AuxId[overlay_alpha_layer_id[i]] shall be equal to overlay_alpha_aux_id_minus128 + 128 for all values of i in the range of 0 to num_overlays_minus1, inclusive.

num_overlay_elements_minus1[i] indicates the number of overlay elements in the i-th overlay. num_overlay_elements_minus1[i] shall be in the range of 0 to 255, inclusive. When not present, the value of num_overlay_elements_minus1[i] is inferred to be equal to 0.

overlay_element_label_min[i][j] and **overlay_element_label_max**[i][j] indicate the minimum and maximum values, respectively, of the range of sample values corresponding to the j-th overlay element of the i-th overlay. The length of the **overlay_element_label_min**[i][j] and the **overlay_element_label_max**[i][j] syntax elements is **overlay_element_label_min_max_length_minus8** + 8 bits.

The variable **overlayElementId**[i][x][y] specifying the overlay element identifier of the i-th overlay for the sample location (x, y) relative to the top-left sample is derived as follows, where **p**[i][x][y] refers to the luma sample at location (x, y) in the decoded label auxiliary picture of the i-th overlay:

```

for( y = 0; y < pic_height_in_luma_samples; y++ )
  for( x = 0; x < pic_width_in_luma_samples; x++ )
    for( i = 0; i <= number_overlays_minus1[ i ] ) {
      overlayElementId[ i ][ x ][ y ] = 0
      for( j = 0; j <= num_overlay_elements_minus1[ i ]; j++ )
        if( p[ i ][ x ][ y ] >= overlay_element_label_min[ i ][ j ] &&
            p[ i ][ x ][ y ] <= overlay_element_label_max[ i ][ j ] )
          overlayElementId[ i ][ x ][ y ] = j
    }

```

(F-96)

overlay_zero_bit shall be equal to 0.

overlay_language[i] contains a language tag as specified by IETF RFC 5646 followed by a null termination byte equal to 0x00. The length of the **overlay_language**[i] syntax element shall be less than or equal to 255 bytes, not including the null termination byte.

overlay_name[i] indicates the name of the i-th overlay. The length of the **overlay_name**[i] syntax element shall be less than or equal to 255 bytes, not including the null termination byte.

overlay_element_name[i][j] indicates the name of the j-th overlay element of the i-th overlay. The length of the **overlay_element_name**[i][j] syntax element shall be less than or equal to 255 bytes, not including the null termination byte.

overlay_info_persistence_flag specifies the persistence of the overlay information SEI message. **overlay_info_persistence_flag** equal to 0 specifies that the overlay information SEI message applies to the current decoded picture only.

When an access unit contains an auxiliary picture **picA** with **nuh_layer_id** equal to **nuhLayerIdA** and **AuxId**[**nuhLayerIdA**] in the range of 128..159, and **nuhLayerIdA** is equal to any of **overlay_content_layer_id**[i], **overlay_label_layer_id**[i], **overlay_alpha_layer_id**[i], **overlay_info_persistence_flag** equal to 1 specifies that the overlay information SEI message persists for the CLVS containing the auxiliary picture **picA** in output order until one or more of the following conditions are true:

- A new CLVS begins for the layer containing the auxiliary picture **picA**.
- A new CLVS begins for the layer containing the primary picture associated with the auxiliary picture **picA**.
- The bitstream ends.
- A picture **picB** in an access unit containing an overlay information SEI message is output for which **PicOrderCnt**(**picB**) is greater than **PicOrderCnt**(**picA**), where **PicOrderCnt**(**picB**) and **PicOrderCnt**(**picA**) are the **PicOrderCntVal** values of **picB** and **picA**, respectively, immediately after the invocation of the decoding process for picture order count for **picB**.

F.14.3.10 Temporal motion vector prediction constraints SEI message semantics

The temporal motion vector prediction constraints SEI message indicates constraints on collocated pictures for temporal motion vector prediction. This SEI message may be used to determine whether the motion vectors of earlier pictures in decoding order no longer need to be stored and whether the motion vectors of the current picture and subsequent pictures need to be stored.

The temporal motion vector prediction constraints SEI message is a prefix SEI message. The temporal motion vector prediction constraints SEI message may be present in an access unit with **TemporalId** equal to 0 and shall not be present in an access unit with **TemporalId** greater than 0.

The following semantics apply separately to each **nuh_layer_id** **targetLayerId** among the **nuh_layer_id** values to which the temporal motion vector prediction constraints SEI message applies. Let **associatedLayerIdList** consist of each **targetLayerId** value to which this temporal motion vector prediction constraints SEI message applies.

Let a set of pictures **associatedPicSet** be the pictures with **nuh_layer_id** equal to **targetLayerId** from the access unit containing the SEI message, inclusive, up to but not including the first of any of the following in decoding order:

- The next access unit, in decoding order, that contains a temporal motion vector prediction constraints SEI message with an associatedLayerIdList that contains targetLayerId.
- The first picture of the next CLVS, in decoding order, of the layer with nuh_layer_id equal to targetLayerId.

prev_pics_not_used_flag equal to 1 indicates that the syntax elements for all coded pictures that are within or follow the access unit containing the current picture in decoding order are constrained such that no temporal motion vector from any picture that has nuh_layer_id equal to any value in associatedLayerIdList and precedes the access unit containing the current picture in decoding order is used directly or indirectly in decoding of any coded picture that is within or follows the access unit containing the current picture in decoding order. **prev_pics_not_used_flag** equal to 0 indicates that the bitstream may or may not fulfill the constraints indicated by **prev_pics_not_used_flag** equal to 1.

NOTE 1 – When **prev_pics_not_used_flag** is equal to 1, decoders may empty the "motion vector storage" for all reference pictures with nuh_layer_id equal to targetLayerId in the decoded picture buffer.

prev_pics_not_used_flag shall be equal to 1 when both of the following conditions are true:

- **no_intra_layer_col_pic_flag** is equal to 1 in the previous temporal motion vector prediction constraints SEI message applying to nuh_layer_id equal to targetLayerId.
- The previous temporal motion vector prediction constraints SEI message applying to nuh_layer_id equal to targetLayerId and the current temporal motion vector prediction constraints SEI message apply to the same CLVS of the layer with nuh_layer_id equal to targetLayerId.

no_intra_layer_col_pic_flag equal to 1 indicates the following:

- If NumDirectRefLayers[targetLayerId] is equal to 0, slice_temporal_mvp_enabled_flag is not present or is equal to 0 in each picture in associatedPicSet.
- Otherwise, all the pictures in associatedPicSet do not use temporal motion vector prediction or use collocated pictures with nuh_layer_id different from targetLayerId.

When **no_intra_layer_col_pic_flag** is equal to 0, no constraint on the collocated picture of the pictures with nuh_layer_id equal to targetLayerId is indicated.

Let NoIntraLayerColPicFlag[targetLayerId] be equal to **no_intra_layer_col_pic_flag**.

NOTE 2 – The motion vectors of the current picture with nuh_layer_id equal to layerId have to be stored when they may be used for temporal motion vector prediction of other pictures in the same layer or when they may be used for inter-layer motion prediction. In other words, the motion vectors of the current picture have to be stored when at least one of the following is true:

- **sps_temporal_mvp_enabled_flag** in the active SPS for the current picture is equal to 1 and NoIntraLayerColPicFlag[layerId] is equal 0.
- NoIntraLayerColPicFlag[layerId] is equal to 1 and there is a nuh_layer_id value nuhLayerIdA such that VpsInterLayerMotionPredictionEnabled[LayerIdxInVps[nuhLayerIdA]][LayerIdxInVps[layerId]] is equal to 1.

NOTE 3 – The motion vectors of a picture with nuh_layer_id equal to layerId need no longer be stored when the picture is marked as "unused for reference", or the picture is not used for temporal motion vector prediction of other pictures in the same layer and all pictures in the same access unit that may use the picture as a reference for inter-layer motion prediction have been decoded, or the access unit containing the picture precedes the current access unit in decoding order, where this SEI message is present with associatedLayerIdList including the nuh_layer_id of the picture and **prev_pics_not_used_flag** equal to 1.

F.14.3.11 Frame-field information SEI message semantics

The frame-field information SEI message may be used to indicate how the associated picture should be displayed, the source scan type of the associated picture, and whether the associated picture is a duplicate of a previous picture, in output order, of the same layer.

The following semantics apply separately to each nuh_layer_id targetLayerId among the nuh_layer_id values to which the frame-field information SEI message applies.

A frame-field information SEI message associated with nuh_layer_id equal to targetLayerId shall be present in an access unit, when all of the following conditions are true:

- A picture with nuh_layer_id equal to targetLayerId is present in the access unit.
- **frame_field_info_present_flag** is equal to 1 in the active SPS for the layer with nuh_layer_id equal to targetLayerId.
- targetLayerId is greater than 0 or none of the following conditions is true:
 - A non-scalable-nested picture timing SEI message is present in the access unit.
 - A picture timing SEI message directly contained in a scalable nesting SEI message is present in the access unit.

A frame-field information SEI message that applies to a particular set of layers shall not be present when one or more of the following conditions are true:

- The value of `field_seq_flag` is not the same for all active SPSs for the particular set of layers.
- The values of `general_progressive_source_flag` and `general_interlaced_source_flag` are not identical, respectively, for all the `profile_tier_level()` syntax structures that apply to the layers to which the frame-field information SEI message applies.

The semantics of `ffinfo_pic_struct`, `ffinfo_source_scan_type` and `ffinfo_duplicate_flag` apply layer-wise to each value of `targetLayerId`.

`ffinfo_pic_struct` has the same semantics as the `pic_struct` syntax element in the picture timing SEI message.

`ffinfo_source_scan_type` has the same semantics as the `source_scan_type` syntax element in the picture timing SEI message.

`ffinfo_duplicate_flag` has the same semantics as the `duplicate_flag` syntax element in the picture timing SEI message.

F.15 Video usability information

F.15.1 General

The specifications in clause E.1 apply.

F.15.2 VUI syntax

The specifications in clause E.2 and its subclauses apply.

F.15.3 VUI semantics

F.15.3.1 VUI parameters semantics

The specifications in clause E.3.1 apply by replacing the semantics of `field_seg_flag`, `frame_field_info_present_flag` and `vui_timing_info_present_flag` with those below and with the following additions:

- It is a requirement of bitstream conformance that, when `nuh_layer_id` `layerId` is greater than 0 and `NumDirectRefLayers[layerId]` is greater than 0, `video_signal_type_present_flag` present in or inferred for the active SPS for `nuh_layer_id` equal to `layerId` shall be equal to 0.
- When the current picture has `nuh_layer_id` `layerIdCurr` greater than 0, either `NumDirectRefLayers[layerIdCurr]` is greater than 0 or `MultiLayerExtSpsFlag` derived from the active SPS for the `nuh_layer_id` equal to `layerIdCurr` is equal to 1 and the active SPS for `nuh_layer_id` equal to `layerIdCurr` contains the VUI parameters syntax structure, the following applies:
 - The values of `video_format`, `video_full_range_flag`, `colour_primaries`, `transfer_characteristics` and `matrix_coeffs` are inferred to be equal to `video_vps_format`, `video_full_range_vps_flag`, `colour_primaries_vps`, `transfer_characteristics_vps` and `matrix_coeffs_vps`, respectively, of the `vps_video_signal_info_idx[j]`-th `video_signal_info()` syntax structure in the active VPS where `j` is equal to `LayerIdxInVps[layerIdCurr]`.
 - The values of `video_format`, `video_full_range_flag`, `colour_primaries`, `transfer_characteristics` and `matrix_coeffs` signalled in the active SPS for the layer with `nuh_layer_id` equal to `layerIdCurr` are ignored.

NOTE 1 – The values are inferred from the VPS when a non-base layer refers to an SPS that is also referred to by the base layer, in which case the SPS has `nuh_layer_id` equal to 0. For the base layer, the values of these parameters in the active SPS for the base layer apply.

`field_seq_flag` equal to 1 indicates that the layers for which the SPS is an active SPS within the CVS convey pictures that represent fields and specifies the following:

- When the SPS is an active SPS for `nuh_layer_id` equal to 0, a picture timing SEI message that is not scalable-nested or that is directly contained in a scalable nesting SEI message and applies to `nuh_layer_id` equal to 0 shall be present in every such access unit of the current CVS that contains a coded picture with `nuh_layer_id` equal to 0.
- When the SPS is an active SPS for the `nuh_layer_id` value `nuhLayerId` greater than 0, a frame-field information SEI message shall be present for `nuh_layer_id` equal to `nuhLayerId` in every access unit containing a picture for the current CLVS of the layer with `nuh_layer_id` equal to `nuhLayerId`.

`field_seq_flag` equal to 0 indicates that the layers for which the SPS is an active SPS within the CVS convey pictures that represent frames and that a picture timing SEI message or a frame-field information SEI message may or may not be present for the pictures within the CVS belonging to any layer for which the SPS is an active SPS. When `field_seq_flag` is not present, it is inferred to be equal to 0. When `general_frame_only_constraint_flag` is present in the SPS and is equal to 1, the value of `field_seq_flag` shall be equal to 0. When `general_frame_only_constraint_flag` is present in the active VPS, applies for a layer for which the SPS is an active SPS and is equal to 1, the value of `field_seq_flag` shall be equal to 0.

NOTE 2 – The specified decoding process does not treat access units conveying pictures that represent fields or frames differently. A sequence of pictures that represent fields would therefore be coded with the picture dimensions of an individual field. For example, access units containing pictures that represent 1080i fields would commonly have cropped output dimensions of 1920x540, while the sequence picture rate would commonly express the rate of the source fields (typically between 50 and 60 Hz), instead of the source frame rate (typically between 25 and 30 Hz).

frame_field_info_present_flag equal to 1 specifies that picture timing SEI messages or frame-field information SEI messages are present for every picture for which this SPS is the active SPS and the picture timing SEI messages, when present, include the `pic_struct`, `source_scan_type`, and `duplicate_flag` syntax elements. **frame_field_info_present_flag** equal to 0 specifies that the `pic_struct` syntax element is not present in picture timing SEI messages associated with pictures for which the SPS is the active SPS.

When `frame_field_info_present_flag` is present and either or both of the following conditions are true, `frame_field_info_present_flag` shall be equal to 1:

- `field_seq_flag` is equal to 1.
- `general_progressive_source_flag` and `general_interlaced_source_flag` are present in this SPS, `general_progressive_source_flag` is equal to 1 and `general_interlaced_source_flag` is equal to 1.

When `frame_field_info_present_flag` is not present, its value is inferred as follows:

- If `general_progressive_source_flag` and `general_interlaced_source_flag` are present in this SPS, `general_progressive_source_flag` is equal to 1 and `general_interlaced_source_flag` is equal to 1, `frame_field_info_present_flag` is inferred to be equal to 1.
- Otherwise, `frame_field_info_present_flag` is inferred to be equal to 0.

vui_timing_info_present_flag equal to 1 specifies that `vui_num_units_in_tick`, `vui_time_scale`, `vui_poc_proportional_to_timing_flag` and `vui_hrd_parameters_present_flag` are present in the `vui_parameters()` syntax structure. **vui_timing_info_present_flag** equal to 0 specifies that `vui_num_units_in_tick`, `vui_time_scale`, `vui_poc_proportional_to_timing_flag` and `vui_hrd_parameters_present_flag` are not present in the `vui_parameters()` syntax structure. It is a requirement of bitstream conformance that, when `MultiLayerExtSpsFlag` is equal to 1, `vui_timing_info_present_flag` shall be equal to 0.

F.15.3.2 HRD parameters semantics

The specifications in clause E.3.2 apply with the replacement of each instance of "access unit level" and "sub-picture level" with "partition unit level" and "sub-partition level", respectively, and with the following additions:

`initial_cpb_removal_delay_length_minus1` plus 1 within the *j*-th `hrd_parameters()` syntax structure in the VPS specifies the length, in bits, of the `nal_initial_arrival_delay[k]` and `vcl_initial_arrival_delay[k]` syntax elements of the bitstream partition initial arrival time SEI message that is contained in a bitstream partition nesting SEI message within a scalable nesting SEI message with values of `MaxTemporalId[0]`, `sei_ols_idx`, `sei_partitioning_scheme_idx` and `bsp_idx` such that `bsp_hrd_idx[sei_ols_idx][sei_partitioning_scheme_idx][MaxTemporalId[0]][k][bsp_idx]` is equal to *j*. When the `initial_cpb_removal_delay_length_minus1` syntax element is not present, it is inferred to be equal to 23.

It is a requirement of bitstream conformance that the value of `sub_pic_hrd_params_present_flag` shall be the same for all `hrd_parameters()` syntax structures that apply to at least one bitstream partition of a particular output layer set.

F.15.3.3 Sub-layer HRD parameters semantics

The specifications in clause E.3.3 apply.

Annex G

Multiview high efficiency video coding

(This annex forms an integral part of this Recommendation | International Standard.)

G.1 Scope

This annex specifies syntax, semantics and decoding processes for multiview high efficiency video coding that use the syntax, semantics and decoding processes specified in clauses 2-10 and Annexes A-F. This annex also specifies profiles, tiers and levels for multiview high efficiency video coding.

G.2 Normative references

The list of normative references in clause F.2 applies.

G.3 Definitions

The specifications in clause F.3 and its subclauses apply.

G.4 Abbreviations

The specifications in clause F.4 apply.

G.5 Conventions

The specifications in clause F.5 apply.

G.6 Bitstream and picture formats, partitionings, scanning processes, and neighbouring relationships

The specifications in clause F.6 apply.

G.7 Syntax and semantics

The specifications in clause F.7 and its subclauses apply.

G.8 Decoding processes

G.8.1 General decoding process

G.8.1.1 General

The specifications of clause F.8.1.1 apply.

G.8.1.2 Decoding process for a coded picture with `nuh_layer_id` greater than 0

The decoding process for the current picture CurrPic is as follows:

1. The decoding of NAL units is specified in clause G.8.2.
2. The processes in clauses G.8.1.3 and F.8.3.4 specify the following decoding processes using syntax elements in the slice segment layer and above:
 - Prior to decoding the first slice of the current picture, clause G.8.1.3 is invoked.
 - At the beginning of the decoding process for each P or B slice, the decoding process for reference picture lists construction specified in clause F.8.3.4 is invoked for derivation of reference picture list 0 (RefPicList0), and when decoding a B slice, reference picture list 1 (RefPicList1).
3. The processes in clauses G.8.4, G.8.5, G.8.6 and G.8.7 specify decoding processes using syntax elements in all syntax structure layers. It is a requirement of bitstream conformance that the coded slices of the picture shall contain slice segment data for every CTU of the picture, such that the division of the picture into slices, the division of the slices into slice segments and the division of the slice segments into CTUs each form a partitioning of the picture.

G.8.1.3 Decoding process for inter-layer reference picture set

Outputs of this process are updated lists of inter-layer reference pictures RefPicSetInterLayer0 and RefPicSetInterLayer1 and the variables NumActiveRefLayerPics0 and NumActiveRefLayerPics1.

The variable currLayerId is set equal to nuh_layer_id of the current picture.

The lists RefPicSetInterLayer0 and RefPicSetInterLayer1 are first emptied, NumActiveRefLayerPics0 and NumActiveRefLayerPics1 are set equal to 0 and the following applies:

```
for( i = 0; i < NumActiveRefLayerPics; i++ ) {
    refPicSet0Flag =
        ( ( ViewId[ currLayerId ] <= ViewId[ 0 ] && ViewId[ currLayerId ] <=
ViewId[ RefPicLayerId[ i ] ] ) ||
        ( ViewId[ currLayerId ] >= ViewId[ 0 ] && ViewId[ currLayerId ] >=
ViewId[ RefPicLayerId[ i ] ] ) )
    if( there is a picture picX in the DPB that is in the same access unit as the current picture and has
        nuh_layer_id equal to RefPicLayerId[ i ] ) {
        if( refPicSet0Flag ) {
            RefPicSetInterLayer0[ NumActiveRefLayerPics0 ] = picX
            RefPicSetInterLayer0[ NumActiveRefLayerPics0++ ] is marked as "used for long-term
reference"
        } else {
            RefPicSetInterLayer1[ NumActiveRefLayerPics1 ] = picX
            RefPicSetInterLayer1[ NumActiveRefLayerPics1++ ] is marked as "used for long-term
reference"
        }
    } else {
        if( refPicSet0Flag )
            RefPicSetInterLayer0[ NumActiveRefLayerPics0++ ] = "no reference picture"
        else
            RefPicSetInterLayer1[ NumActiveRefLayerPics1++ ] = "no reference picture"
    }
}
```

(G-1)

There shall be no entry equal to "no reference picture" in RefPicSetInterLayer0 or RefPicSetInterLayer1.

There shall be no picture that has discardable_flag equal to 1 in RefPicSetInterLayer0 or RefPicSetInterLayer1.

If the current picture is a RADL picture, there shall be no entry in RefPicSetInterLayer0 or RefPicSetInterLayer1 that is a RASL picture.

NOTE – An access unit may contain both RASL and RADL pictures.

G.8.2 NAL unit decoding process

The specifications in clause F.8.2 apply.

G.8.3 Slice decoding processes

The specifications in clause F.8.3 and its subclauses apply.

G.8.4 Decoding process for coding units coded in intra prediction mode

The specifications in clause F.8.4 apply.

G.8.5 Decoding process for coding units coded in inter prediction mode

The specifications in clause F.8.5 apply.

G.8.6 Scaling, transformation and array construction process prior to deblocking filter process

The specifications in clause F.8.6 apply.

G.8.7 In-loop filter process

The specifications in clause F.8.7 apply.

G.9 Parsing process

The specifications in clause F.9 apply.

G.10 Specification of bitstream subsets

The specifications in clause F.10 and its subclauses apply.

G.11 Profiles, tiers and levels

G.11.1 Profiles

G.11.1.1 Multiview Main profile

For a layer in an output operation point associated with an OLS in a bitstream, the layer being conforming to the Multiview Main profile, the following applies:

- Let `olsIdx` be the OLS index of the OLS, the sub-bitstream `subBitstream` and the base layer sub-bitstream `baseBitstream` are derived as specified in clause F.11.3.

When `vps_base_layer_internal_flag` is equal to 1, the base layer sub-bitstream `baseBitstream` shall obey the following constraints:

- The base layer sub-bitstream `baseBitstream` shall be indicated to conform to the Main profile.

The sub-bitstream `subBitstream` shall obey the following constraints:

- All active VPSs shall have `vps_num_rep_formats_minus1` in the range of 0 to 15, inclusive.
- All active SPSs for layers in `subBitstream` shall have `chroma_format_idc` equal to 1 only.
- All active SPSs for layers in `subBitstream` shall have `transform_skip_rotation_enabled_flag`, `transform_skip_context_enabled_flag`, `implicit_rdpkm_enabled_flag`, `explicit_rdpkm_enabled_flag`, `extended_precision_processing_flag`, `intra_smoothing_disabled_flag`, `high_precision_offsets_enabled_flag`, `persistent_rice_adaptation_enabled_flag` and `cabac_bypass_alignment_enabled_flag`, when present, equal to 0 only.
- `CtbLog2SizeY` derived from all active SPSs for layers in `subBitstream` shall be in the range of 4 to 6, inclusive.
- All active PPSs for layers in `subBitstream` shall have `log2_max_transform_skip_block_size_minus2` and `chroma_qp_offset_list_enabled_flag`, when present, equal to 0 only.
- `ScalabilityId[j][smIdx]` derived according to any active VPS shall be equal to 0 for any `smIdx` value not equal to 1 or 3 and for any value of `j` such that `layer_id_in_nuh[j]` is among `layerIdListTarget` that was used to derive `subBitstream`.
- When `NumLayersInIdList[OlsIdxToLsIdx[olsIdx]]` is equal to 2, `output_layer_flag[olsIdx][j]` derived according to any active VPS shall be equal to 1 for `j` in the range of 0 to 1, inclusive, for `subBitstream`.
- All active VPSs shall have `alt_output_layer_flag[olsIdx]` equal to 0 only.
- When `ViewOrderIdx[i]` derived according to any active VPS is equal to 1 for the layer with `nuh_layer_id` equal to `i` in `subBitstream`, `inter_view_mv_vert_constraint_flag` shall be equal to 1 in the `sps_multilayer_extension()` syntax structure in each active SPS for that layer.
- When `ViewOrderIdx[i]` derived according to any active VPS is greater than 0 for the layer with `nuh_layer_id` equal to `i` in `subBitstream`, `num_ref_loc_offsets` shall be equal to 0 in each active PPS for that layer.
- When `ViewOrderIdx[i]` derived according to any active VPS is greater than 0 for the layer with `nuh_layer_id` equal to `i` in `subBitstream`, the values of `pic_width_in_luma_samples` and `pic_height_in_luma_samples` in each active SPS for that layer shall be equal to the values of `pic_width_in_luma_samples` and `pic_height_in_luma_samples`, respectively, in each active SPS for all reference layers of that layer.
- For a layer with `nuh_layer_id` `iNuhLid` equal to any value included in `layerIdListTarget` that was used to derive `subBitstream`, the value of `NumRefLayers[iNuhLid]`, which specifies the total number of direct and indirect reference layers and is derived as specified in F.7.4.3.1, shall be less than or equal to 4.
- All active SPSs for layers in `subBitstream` shall have `sps_range_extension_flag` and `sps_scc_extension_flag` equal to 0 only.
- All active PPSs for layers in `subBitstream` shall have `pps_range_extension_flag` and `pps_scc_extension_flag` equal to 0 only.

- All active SPSs for layers in subBitstream shall have `bit_depth_luma_minus8` equal to 0 only.
- All active SPSs for layers in subBitstream shall have `bit_depth_chroma_minus8` equal to 0 only.
- All active PPSs for layers in subBitstream shall have `colour_mapping_enabled_flag` equal to 0 only.
- When an active PPS for any layer in subBitstream has `tiles_enabled_flag` equal to 1, it shall have `entropy_coding_sync_enabled_flag` equal to 0.
- When an active PPS for any layer in subBitstream has `tiles_enabled_flag` equal to 1, `ColumnWidthInLumaSamples[i]` shall be greater than or equal to 256 for all values of `i` in the range of 0 to `num_tile_columns_minus1`, inclusive and `RowHeightInLumaSamples[j]` shall be greater than or equal to 64 for all values of `j` in the range of 0 to `num_tile_rows_minus1`, inclusive.
- The number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing `coding_tree_unit()` data for any CTU shall be less than or equal to $5 * \text{RawCtuBits} / 3$.
- `general_level_idc` and `sub_layer_level_idc[i]` for all values of `i` in active SPSs for any layer in subBitstream shall not be equal to 255 (which indicates level 8.5).
- The tier and level constraints specified for the Multiview Main profile in clause G.11.2 shall be fulfilled.
- For any active VPS, `ViewOrderIdx[i]` shall be greater than `ViewOrderIdx[j]` for any values of `i` and `j` among `layerIdListTarget` that was used to derive subBitstream such that `AuxIdx[i]` is equal to `AuxIdx[j]` and `i` is greater than `j`.

In the remainder of this clause and clause G.11.2.1, all syntax elements in the `profile_tier_level()` syntax structure refer to those in the `profile_tier_level()` syntax structure associated with the layer.

Conformance of a layer in an output operation point associated with an OLS in a bitstream to the Multiview Main profile is indicated as follows:

- If `OpTid` of the output operation point is equal to `vps_max_sub_layer_minus1`, the conformance is indicated by `general_profile_idc` being equal to 6 or `general_profile_compatibility_flag[6]` being equal to 1 and `general_max_12bit_constraint_flag` being equal to 1, `general_max_10bit_constraint_flag` being equal to 1, `general_max_8bit_constraint_flag` being equal to 1, `general_max_422chroma_constraint_flag` being equal to 1, `general_max_420chroma_constraint_flag` being equal to 1, `general_max_monochrome_constraint_flag` being equal to 0, `general_intra_constraint_flag` being equal to 0 and `general_one_picture_only_constraint_flag` being equal to 0 and `general_lower_bit_rate_constraint_flag` being equal to 1.
- Otherwise (`OpTid` of the output operation point is less than `vps_max_sub_layer_minus1`), the conformance is indicated by `sub_layer_profile_idc[OpTid]` being equal to 6 or `sub_layer_profile_compatibility_flag[OpTid][6]` being equal to 1 and `sub_layer_max_12bit_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_10bit_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_8bit_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_422chroma_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_420chroma_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_monochrome_constraint_flag[OpTid]` being equal to 0, `sub_layer_intra_constraint_flag[OpTid]` being equal to 0 and `sub_layer_one_picture_only_constraint_flag[OpTid]` being equal to 0 and `sub_layer_lower_bit_rate_constraint_flag[OpTid]` being equal to 1.

G.11.2 Tiers and levels

G.11.2.1 General tier and level limits

For purposes of comparison of tier capabilities, the tier with `general_tier_flag` or `sub_layer_tier_flag[i]` equal to 0 is considered to be a lower tier than the tier with `general_tier_flag` or `sub_layer_tier_flag[i]` equal to 1.

For purposes of comparison of level capabilities, a particular level of a specific tier is considered to be a lower level than some other level of the same tier when the value of the `general_level_idc` or `sub_layer_level_idc[i]` of the particular level is less than that of the other level.

The following is specified for expressing the constraints in this clause and clause G.11.2.2:

- The value of each of the variables `CpbVclFactor`, `CpbNalFactor`, `FormatCapabilityFactor` and `MinCrScaleFactor` is the same as that specified in Table A.10 for the Main profile.
- Let access unit `n` be the `n`-th access unit in decoding order, with the first access unit being access unit 0 (i.e., the 0-th access unit).
- Let the variable `fR` be set equal to $1 \div 300$.
- Let the variable `olsIdx` be the index of the OLS.

- For each layer with `nuh_layer_id` equal to `currLayerId`, let the variable `layerSizeInSamplesY` be derived as follows:

$$\text{layerSizeInSamplesY} = \text{pic_width_vps_in_luma_samples} * \text{pic_height_vps_in_luma_samples} \quad (\text{G-2})$$

where `pic_width_vps_in_luma_samples` and `pic_height_vps_in_luma_samples` are found in the `vps_rep_format_idx[LayerIdxInVps[currLayerId]]-th rep_format()` syntax structure in the VPS.

Each layer with `nuh_layer_id` equal to `currLayerId` conforming to a profile at a specified tier and level shall obey the following constraints for each bitstream conformance test as specified in clause F.13, where "access unit" is used to denote the picture unit in the layer and the CPB is understood to be the BPB:

- The value of `layerSizeInSamplesY` shall be less than or equal to `MaxLumaPs`, where `MaxLumaPs` is specified in Table A.8 for the tier and level of the layer.
- The value of `pic_width_vps_in_luma_samples` of the `vps_rep_format_idx[LayerIdxInVps[currLayerId]]-th rep_format()` syntax structure in the VPS shall be less than or equal to $\text{Sqrt}(\text{MaxLumaPs} * 8)$.
- The value of `pic_height_vps_in_luma_samples` of the `vps_rep_format_idx[LayerIdxInVps[currLayerId]]-th rep_format()` syntax structure in the VPS shall be less than or equal to $\text{Sqrt}(\text{MaxLumaPs} * 8)$.
- The value of `max_vps_dec_pic_buffering_minus1[olsIdx][LayerIdxInVps[currLayerId]][HighestTid]` shall be less than or equal to `MaxDpbSize` as derived by Equation A-2, with `PicSizeInSamplesY` being replaced with `layerSizeInSamplesY`, for the tier and level of the layer.
- For level 5 and higher levels, the value of `CtbSizeY` for the layer shall be equal to 32 or 64.
- The value of `NumPicTotalCurr` for each picture in the layer shall be less than or equal to 8.
- When decoding each coded picture in the layer, the value of `num_tile_columns_minus1` shall be less than `MaxTileCols` and `num_tile_rows_minus1` shall be less than `MaxTileRows`, where `MaxTileCols` and `MaxTileRows` are specified in Table A.8 for the tier and level of the layer.
- For the VCL HRD parameters of the layer, `CpbSize[i]` shall be less than or equal to `CpbVclFactor * MaxCPB` for at least one of the delivery schedules identified by `bsp_sched_idx[olsIdx][0][HighestTid][combIdx][LayerIdxInVps[currLayerId]]` for `combIdx` ranging from 0 to `num_bsp_schedules_minus1[olsIdx][0][HighestTid]`, inclusive, where `CpbSize[i]` is specified in clause F.13.1 and `MaxCPB` is specified in Table A.8 for the tier and level of the layer in units of `CpbVclFactor` bits.
- For the NAL HRD parameters of the layer, `CpbSize[i]` shall be less than or equal to `CpbNalFactor * MaxCPB` for at least one of the delivery schedules identified by `bsp_sched_idx[olsIdx][0][HighestTid][combIdx][LayerIdxInVps[currLayerId]]` for `combIdx` ranging from 0 to `num_bsp_schedules_minus1[olsIdx][0][HighestTid]`, inclusive, where `CpbSize[i]` is specified in clause F.13.1 and `MaxCPB` is specified in Table A.8 for the tier and level of the layer in units of `CpbNalFactor` bits.

Table A.8 specifies the limits for each level of each tier for levels other than level 8.5.

A tier and level to which a layer in an output operation point associated with an OLS in a bitstream conforms are indicated by the syntax elements `general_tier_flag` and `general_level_idc` if `OpTid` of the output layer set is equal to `vps_max_sub_layer_minus1`, and by the syntax elements `sub_layer_tier_flag[OpTid]` and `sub_layer_level_idc[OpTid]` otherwise, as follows:

- If the specified level is not level 8.5, `general_tier_flag` or `sub_layer_tier_flag[OpTid]` equal to 0 indicates conformance to the Main tier, and `general_tier_flag` or `sub_layer_tier_flag[OpTid]` equal to 1 indicates conformance to the High tier, according to the tier constraints specified in Table A.8, and `general_tier_flag` and `sub_layer_tier_flag[OpTid]` shall be equal to 0 for levels below level 4 (corresponding to the entries in Table A.8 marked with "-"). Otherwise (the specified level is level 8.5), it is a requirement of bitstream conformance that `general_tier_flag` and `sub_layer_tier_flag[OpTid]` shall be equal to 1 and the value 0 for `general_tier_flag` and `sub_layer_tier_flag[OpTid]` is reserved for future use by ITU-T | ISO/IEC and decoders shall ignore the value of `general_tier_flag` and `sub_layer_tier_flag[OpTid]`.
- `general_level_idc` and `sub_layer_level_idc[OpTid]` shall be set equal to a value of 30 times the level number specified in Table A.8.

G.11.2.2 Profile-specific tier and level limits for the Multiview Main profile

The following is specified for expressing the constraints in this clause:

- The variable `HbrFactor` is set equal to 1.

- The variable BrVclFactor is set equal to $CpbVclFactor * HbrFactor$.
- The variable BrNalFactor is set equal to $CpbNalFactor * HbrFactor$.
- The variable MinCr is set equal to $MinCrBase * MinCrScaleFactor \div HbrFactor$, where MinCrBase is specified in Table A.9.

Each layer conforming to the Multiview Main profile at a specified tier and level shall obey the following constraints for each conformance test as specified in clause F.13, where "access unit" is used to denote the picture unit in the layer, and the CPB is understood to be the BPB:

- a) The nominal removal time of access unit n (with n greater than 0) from the CPB, as specified in clause F.13.2.3, shall satisfy the constraint that $AuNominalRemovalTime[n] - AuCpbRemovalTime[n - 1]$ is greater than or equal to $Max(layerSizeInSamplesY \div MaxLumaSr, fR)$, where $layerSizeInSamplesY$ is the value of $layerSizeInSamplesY$ for access unit $n - 1$ and $MaxLumaSr$ is the value specified in Table A.9 that applies to access unit $n - 1$ for the tier and level of the layer.
- b) The difference between consecutive output times of pictures in different access units, as specified in clause F.13.3.3, shall satisfy the constraint that $DpbOutputInterval[n]$ is greater than or equal to $Max(layerSizeInSamplesY \div MaxLumaSr, fR)$, where $layerSizeInSamplesY$ is the value of $layerSizeInSamplesY$ of access unit n and $MaxLumaSr$ is the value specified in Table A.9 for access unit n for the tier and level of the layer, provided that access unit n is an access unit that has a picture that is output and is not the last of such access units.
- c) The removal time of access unit 0 shall satisfy the constraint that the number of coded slice segments in access unit 0 is less than or equal to $Min(Max(1, MaxSliceSegmentsPerPicture * MaxLumaSr / MaxLumaPs * (AuCpbRemovalTime[0] - AuNominalRemovalTime[0]) + MaxSliceSegmentsPerPicture * layerSizeInSamplesY / MaxLumaPs), MaxSliceSegmentsPerPicture)$, for the value of $layerSizeInSamplesY$ of access unit 0, where $MaxSliceSegmentsPerPicture$, $MaxLumaPs$ and $MaxLumaSr$ are the values specified in Table A.8 and Table A.9 for the tier and level of the layer.
- d) The difference between consecutive CPB removal times of access units n and $n - 1$ (with n greater than 0) shall satisfy the constraint that the number of slice segments in access unit n is less than or equal to $Min(Max(1, MaxSliceSegmentsPerPicture * MaxLumaSr / MaxLumaPs * (AuCpbRemovalTime[n] - AuCpbRemovalTime[n - 1])), MaxSliceSegmentsPerPicture)$, where $MaxSliceSegmentsPerPicture$, $MaxLumaPs$ and $MaxLumaSr$ are the values specified in Table A.8 and Table A.9 that apply to access unit n for the tier and level of the layer.
- e) For the VCL HRD parameters for the layer, $BitRate[i]$ shall be less than or equal to $BrVclFactor * MaxBR$ for at least one of the delivery schedules identified by $bsp_sched_idx[olsIdx][0][HighestTid][combIdx][LayerIdxInVps[currLayerId]]$ for $combIdx$ ranging from 0 to $num_bsp_schedules_minus1[olsIdx][0][HighestTid]$, inclusive, where $BitRate[i]$ is specified in clause F.13.1 and $MaxBR$ is specified in Table A.9 in units of $BrVclFactor$ bits/s for the tier and level of the layer.
- f) For the NAL HRD parameters for the layer, $BitRate[i]$ shall be less than or equal to $BrNalFactor * MaxBR$ for at least one of the delivery schedules identified by $bsp_sched_idx[olsIdx][0][HighestTid][combIdx][LayerIdxInVps[currLayerId]]$ for $combIdx$ ranging from 0 to $num_bsp_schedules_minus1[olsIdx][0][HighestTid]$, inclusive, where $BitRate[i]$ is specified in clause F.13.1 and $MaxBR$ is specified in Table A.9 in units of $BrNalFactor$ bits/s for the tier and level of the layer.
- g) The sum of the $NumBytesInNalUnit$ variables for access unit 0 shall be less than or equal to $FormatCapabilityFactor * (Max(layerSizeInSamplesY, fR * MaxLumaSr) + MaxLumaSr * (AuCpbRemovalTime[0] - AuNominalRemovalTime[0])) \div MinCr$ for the value of $layerSizeInSamplesY$ of access unit 0, where $MaxLumaSr$ is specified in Table A.9, and both $MaxLumaSr$ and $FormatCapabilityFactor$ are the values that apply to access unit 0 for the tier and level of the layer.
- h) The sum of the $NumBytesInNalUnit$ variables for access unit n (with n greater than 0) shall be less than or equal to $FormatCapabilityFactor * MaxLumaSr * (AuCpbRemovalTime[n] - AuCpbRemovalTime[n - 1]) \div MinCr$, where $MaxLumaSr$ is specified in Table A.9, and both $MaxLumaSr$ and $FormatCapabilityFactor$ are the values that apply to access unit n for the tier and level of the layer.
- i) The removal time of access unit 0 shall satisfy the constraint that the number of tiles in coded pictures in access unit 0 is less than or equal to $Min(Max(1, MaxTileCols * MaxTileRows * 120 * (AuCpbRemovalTime[0] - AuNominalRemovalTime[0]) + MaxTileCols * MaxTileRows * PicSizeInSamplesY / MaxLumaPs), MaxTileCols * MaxTileRows)$, for the value of $layerSizeInSamplesY$ of access unit 0, where $MaxTileCols$ and $MaxTileRows$ are the values specified in Table A.8 that apply to access unit 0 for the tier and level of the layer.

- j) The difference between consecutive CPB removal times of access units n and $n - 1$ (with n greater than 0) shall satisfy the constraint that the number of tiles in coded pictures in access unit n is less than or equal to $\text{Min}(\text{Max}(1, \text{MaxTileCols} * \text{MaxTileRows} * 120 * (\text{AuCpbRemovalTime}[n] - \text{AuCpbRemovalTime}[n - 1])), \text{MaxTileCols} * \text{MaxTileRows})$, where MaxTileCols and MaxTileRows are the values specified in Table A.8 that apply to access unit n for the tier and level of the layer.

G.11.3 Decoder capabilities

When a decoder conforms to any profile specified in Annex G, it shall also have the INBLD capability specified in clause F.11.1.

Clause F.11.2 specifies requirements for a decoder conforming to any profile specified in Annex G.

G.12 Byte stream format

The specifications in clause F.12 apply.

G.13 Hypothetical reference decoder

The specifications in clause F.13 and its subclauses apply.

G.14 Supplemental enhancement information

G.14.1 General

The specifications in clause F.14.1 apply.

G.14.2 SEI payload syntax

G.14.2.1 General SEI payload syntax

The specifications in clause F.14.2.1 apply.

G.14.2.2 Annex D and Annex F SEI message syntax for multiview high efficiency video coding

The specifications in clauses F.14.2.2 through F.14.2.11 apply.

G.14.3 SEI payload semantics

G.14.3.1 General SEI payload semantics

The specifications in clause F.14.3.1 apply with the following modifications and additions:

The list `VclAssociatedSeiList` is set to consist of the `payloadType` values 2, 3, 6, 9, 15, 16, 17, 19, 22, 23, 45, 47, 56, 128, 131, 132, 134 to 152, inclusive, 154 to 159, inclusive, 161, 165, 167, 168, 177, 178, 179, 200 to 202, inclusive, and 205.

The list `PicUnitRepConSeiList` is set to consist of the `payloadType` values 0, 1, 2, 6, 9, 15, 16, 17, 19, 22, 23, 45, 47, 56, 128, 129, 131, 132, 133, 135 to 152, inclusive, 154 to 168, inclusive, 176 to 180, inclusive, 200 to 202, inclusive, and 205.

The semantics and persistence scope for each SEI message specified in this annex are specified in the semantics specification for each particular SEI message in the subclauses of this clause.

NOTE – Persistence information for SEI messages specified in this annex is informatively summarized in Table G.1.

Table G.1 – Persistence scope of SEI messages (informative)

SEI message	Persistence scope
3D reference displays information	Specified by the semantics of the SEI message
Depth representation information	Specified by the semantics of the SEI message.
Multiview scene information	The CVS containing the SEI message
Multiview acquisition information	The CVS containing the SEI message
Multiview view position SEI message	The CVS containing the SEI message

G.14.3.2 Annex D and Annex F SEI message semantics for multiview high efficiency video coding

G.14.3.2.1 General

The specifications of clause F.14.3.2 and its subclauses apply with the modifications specified in clause G.14.3.2.2.

G.14.3.2.2 Scalable nesting SEI message semantics for multiview high efficiency video coding

The specifications of clause F.14.3.2.7 apply with the following additions:

An SEI message that has `payloadType` equal to 176 (3D reference displays information) or 180 (multiview view position) shall not be directly contained in a scalable nesting SEI message.

When the scalable nesting SEI message contains an SEI message that has `payloadType` equal to 177, 178 or 179, `bitstream_subset_flag` shall be equal to 0.

G.14.3.2.3 3D reference displays information SEI message semantics

A 3D reference displays information SEI message contains information about the reference display width(s) and reference viewing distance(s) as well as information about the corresponding reference stereo pair(s), i.e., the pair(s) of views to be displayed for the viewer's left and right eyes on the reference display at the reference viewing distance. This information enables a view renderer to generate a proper stereo pair for the target screen width and the viewing distance. The reference display width and viewing distance values are signalled in units of centimetres. The reference pair of view specified in this SEI message can be used to extract or infer parameters related to the distance between the camera centres in the reference stereo pair, which can be used for generation of views for the target display. For multi-view displays, the reference stereo pair corresponds to a pair of views that can be simultaneously observed by the viewer's left and right eyes.

When present, this SEI message shall be associated with an IRAP access unit or with a non-IRAP access unit, when all access units that follow this access unit in the decoding order also follow it in output order. The 3D reference display

information SEI message applies to the current access unit and all the access units which follow this access unit in both the output and decoding order until but not including the next IRAP access unit or the next access unit containing a 3D reference displays information SEI message.

NOTE 1 – The 3D reference displays information SEI message specifies display parameters for which the 3D sequence was optimized and the corresponding reference parameters. Each reference display (i.e., a reference display width and possibly a corresponding viewing distance) is associated with one reference pair of views by signalling their ViewId. The difference between the values of ViewId is referred to as the baseline distance (i.e., the distance between the centres of the cameras used to obtain the video sequence).

The following equations can be used for determining the baseline distance and horizontal shift for the receiver's display when the ratio between the receiver's viewing distance and the reference viewing distance is the same as the ratio between the receiver screen width and the reference screen width:

$$\text{baseline}[i] = \text{refBaseline}[i] * (\text{refDisplayWidth}[i] \div \text{displayWidth}) \quad (\text{G-3})$$

$$\text{shift}[i] = \text{refShift}[i] * (\text{refDisplayWidth}[i] \div \text{displayWidth}) \quad (\text{G-4})$$

where $\text{refBaseline}[i]$ is equal to $\text{right_view_id}[i] - \text{left_view_id}[i]$ signalled in this SEI message. Other parameters related to the view generation may be obtained determined by using a similar equation.

$$\text{parameter}[i] = \text{refParameter}[i] * (\text{refDisplayWidth}[i] \div \text{displayWidth}) \quad (\text{G-5})$$

where $\text{refParameter}[i]$ is a parameter related to view generation that corresponds to the reference pair of views signalled by $\text{left_view_id}[i]$ and $\text{right_view_id}[i]$. In the above equations, the width of the visible part of the display used for showing the video sequence should be understood under "display width". The same equations can also be used for determining the pair of views and horizontal shift or other view synthesis parameters when the viewing distance is not scaled proportionally to the screen width compared to the reference display parameters. In this case, the effect of applying the above equations would be to keep the perceived depth in the same proportion to the viewing distance as in the reference setup.

When the view synthesis related parameters that correspond to the reference stereo pair change from one access unit to another, they should be scaled with the same scaling factor as the parameters in the access unit that the SEI message is associated with. Therefore, the above equation should also be applied to obtain the parameters for a following access unit, where the refParameter is the parameter related to the reference stereo pair associated the following access unit.

The horizontal shift for the receiver's display should also be modified by scaling it with the same factor as that used to scale the baseline distance (or other view synthesis parameters).

prec_ref_display_width specifies the exponent of the maximum allowable truncation error for $\text{refDisplayWidth}[i]$ as given by $2^{-\text{prec_ref_display_width}}$. The value of **prec_ref_display_width** shall be in the range of 0 to 31, inclusive.

ref_viewing_distance_flag equal to 1 indicates the presence of reference viewing distance. **ref_viewing_distance_flag** equal to 0 indicates that the reference viewing distance is not present.

prec_ref_viewing_dist specifies the exponent of the maximum allowable truncation error for $\text{refViewingDist}[i]$ as given by $2^{-\text{prec_ref_viewing_dist}}$. The value of **prec_ref_viewing_dist** shall be in the range of 0 to 31, inclusive.

num_ref_displays_minus1 plus 1 specifies the number of reference displays that are signalled in this SEI message. The value of **num_ref_displays_minus1** shall be in the range of 0 to 31, inclusive.

left_view_id[i] indicates the ViewId of the left view of a stereo pair corresponding to the i-th reference display.

right_view_id[i] indicates the ViewId of the right view of a stereo-pair corresponding to the i-th reference display.

exponent_ref_display_width[i] specifies the exponent part of the reference display width of the i-th reference display. The value of **exponent_ref_display_width**[i] shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value 63 as indicating an unspecified reference display width.

mantissa_ref_display_width[i] specifies the mantissa part of the reference display width of the i-th reference display. The variable **refDispWidthBits** specifying the number of bits of the **mantissa_ref_display_width**[i] syntax element is derived as follows:

- If **exponent_ref_display_width**[i] is equal to 0, **refDispWidthBits** is set equal to $\text{Max}(0, \text{prec_ref_display_width} - 30)$.
- Otherwise ($0 < \text{exponent_ref_display_width}[i] < 63$), **refDispWidthBits** is set equal to $\text{Max}(0, \text{exponent_ref_display_width}[i] + \text{prec_ref_display_width} - 31)$.

exponent_ref_viewing_distance[i] specifies the exponent part of the reference viewing distance of the i-th reference display. The value of **exponent_ref_viewing_distance**[i] shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value 63 as indicating an unspecified reference display width.

mantissa_ref_viewing_distance[i] specifies the mantissa part of the reference viewing distance of the i-th reference display. The variable **refViewDistBits** specifying the number of bits of the **mantissa_ref_viewing_distance**[i] syntax element is derived as follows:

- If `exponent_ref_viewing_distance[i]` is equal to 0, the `refViewDistBits` is set equal to `Max(0, prec_ref_viewing_distance – 30)`.
- Otherwise (`0 < exponent_ref_viewing_distance[i] < 63`), `refViewDistBits` is set equal to `Max(0, exponent_ref_viewing_distance[i] + prec_ref_viewing_distance – 31)`.

The variables in the x row of Table G.2 are derived from the respective variables or values in the e, n and v rows of Table G.2 as follows:

- If e is not equal to 0, the following applies:

$$x = 2^{(e-31)} * (1 + n \div 2^v) \quad (G-6)$$

- Otherwise (e is equal to 0), the following applies:

$$x = 2^{-(30+v)} * n \quad (G-7)$$

NOTE 2 – The above specification is similar to that found in IEC 60559:1989.

Table G.2 – Association between camera parameter variables and syntax elements

x	<code>refDisplayWidth[i]</code>	<code>refViewingDistance[i]</code>
e	<code>exponent_ref_display_width[i]</code>	<code>exponent_ref_viewing_distance[i]</code>
n	<code>mantissa_ref_display_width[i]</code>	<code>mantissa_ref_viewing_distance[i]</code>
v	<code>refDispWidthBits</code>	<code>refViewDistBits</code>

additional_shift_present_flag[i] equal to 1 indicates that the information about additional horizontal shift of the left and right views for the i-th reference display is present in this SEI message. **additional_shift_present_flag[i]** equal to 0 indicates that the information about additional horizontal shift of the left and right views for the i-th reference display is not present in this SEI message.

num_sample_shift_plus512[i] indicates the recommended additional horizontal shift for a stereo pair corresponding to the i-th reference baseline and the i-th reference display.

- If `num_sample_shift_plus512[i]` is less than 512, it is recommended that the left view of the stereo pair corresponding to the i-th reference baseline and the i-th reference display is shifted in the left direction by (`512 – num_sample_shift_plus512[i]`) samples with respect to the right view of the stereo pair.
- Otherwise, if `num_sample_shift_plus512[i]` is equal to 512, it is recommended that shifting is not applied.
- Otherwise, (`num_sample_shift_plus512[i]` is greater than 512), it is recommended that the left view in the stereo pair corresponding to the i-th reference baseline and the i-th reference display should be shifted in the right direction by (`num_sample_shift_plus512[i] – 512`) samples with respect to the right view of the stereo pair.

The value of `num_sample_shift_plus512[i]` shall be in the range of 0 to 1 023, inclusive.

NOTE 3 – Shifting the left view in the left (or right) direction by x samples with respect to the right view can be performed by the following two-step processing:

- 1) Shift the left view by `x / 2` samples in the left (or right) direction and shift the right view by `x / 2` samples in the right (or left) direction.
- 2) Fill the left and right image margins of `x / 2` samples in width in both the left and right views in background colour.

The following explains the recommended shifting processing in the case of shifting the left view in the left direction by x samples with respect to the right view:

```

for( i = x / 2; i < width - x / 2; i++ )
    for( j = 0; j < height; j++ ) {
        leftView[ j ][ i ] = leftView[ j ][ i + x / 2 ]
        rightView[ j ][ width - 1 - i ] = rightView[ j ][ width - 1 - i - x / 2 ]
    }
for( i = 0; i < x / 2; i++ )
    for( j = 0; j < height; j++ ) {
        leftView[ j ][ width - 1 - i ] = leftView[ j ][ i ] = backgroundColour
        rightView[ j ][ width - 1 - i ] = rightView[ j ][ i ] = backgroundColour
    }

```

(G-8)

The following explains the recommended shifting processing in the case of shifting the left view in the right direction by x samples with respect to the right view:

```

for( i = x / 2; i < width - x / 2; i++ )
    for( j = 0; j < height; j++ ) {
        leftView[ j ][ width - 1 - i ] = leftView[ j ][ width - 1 - i - x / 2 ]
        rightView[ j ][ i ] = rightView[ j ][ i + x / 2 ]
    }
for( i = 0; i < x / 2; i++ )
    for( j = 0; j < height; j++ ) {
        leftView[ j ][ width - 1 - i ] = leftView[ j ][ i ] = backgroundColour
        rightView[ j ][ width - 1 - i ] = rightView[ j ][ i ] = backgroundColour
    }

```

(G-9)

The variable backgroundColour may take different values in different systems, for example black or grey.

three_dimensional_reference_displays_extension_flag equal to 0 indicates that no additional data follows within the reference displays SEI message. The value of three_dimensional_reference_displays_extension_flag shall be equal to 0 in bitstreams conforming to this version of this Specification. The value of 1 for three_dimensional_reference_displays_extension_flag is reserved for future use by ITU-T | ISO/IEC. Decoders shall ignore all data that follow the value 1 for three_dimensional_reference_displays_extension_flag in a reference displays SEI message.

G.14.3.3 Depth representation information SEI message semantics

G.14.3.3.1 General

The syntax elements in the depth representation information SEI message specify various parameters for auxiliary pictures of type AUX_DEPTH for the purpose of processing decoded primary and auxiliary pictures prior to rendering on a 3D display, such as view synthesis. Specifically, depth or disparity ranges for depth pictures are specified.

When present, the depth representation information SEI message shall be associated with one or more layers with AuxId value equal to AUX_DEPTH. The following semantics apply separately to each nuh_layer_id targetLayerId among the nuh_layer_id values to which the depth representation information SEI message applies.

When present, the depth representation information SEI message may be included in any access unit. It is recommended that, when present, the SEI message is included for the purpose of random access in an access unit in which the coded picture with nuh_layer_id equal to targetLayerId is an IRAP picture.

For an auxiliary picture with AuxId[targetLayerId] equal to AUX_DEPTH, an associated primary picture, if any, is a picture in the same access unit having AuxId[nuhLayerIdB] equal to 0 such that ScalabilityId[LayerIdxInVps[targetLayerId]][j] is equal to ScalabilityId[LayerIdxInVps[nuhLayerIdB]][j] for all values of j in the range of 0 to 2, inclusive, and 4 to 15, inclusive.

The information indicated in the SEI message applies to all the pictures with nuh_layer_id equal to targetLayerId from the access unit containing the SEI message up to but excluding the next picture, in decoding order, associated with a depth representation information SEI message applicable to targetLayerId or to the end of the CLVS of the nuh_layer_id equal to targetLayerId, whichever is earlier in decoding order.

z_near_flag equal to 0 specifies that the syntax elements specifying the nearest depth value are not present in the syntax structure. z_near_flag equal to 1 specifies that the syntax elements specifying the nearest depth value are present in the syntax structure.

z_far_flag equal to 0 specifies that the syntax elements specifying the farthest depth value are not present in the syntax structure. z_far_flag equal to 1 specifies that the syntax elements specifying the farthest depth value are present in the syntax structure.

d_min_flag equal to 0 specifies that the syntax elements specifying the minimum disparity value are not present in the syntax structure. d_min_flag equal to 1 specifies that the syntax elements specifying the minimum disparity value are present in the syntax structure.

d_max_flag equal to 0 specifies that the syntax elements specifying the maximum disparity value are not present in the syntax structure. d_max_flag equal to 1 specifies that the syntax elements specifying the maximum disparity value are present in the syntax structure.

depth_representation_type specifies the representation definition of decoded luma samples of auxiliary pictures as specified in Table G.3. In Table G.3, disparity specifies the horizontal displacement between two texture views and Z value specifies the distance from a camera.

The variable maxVal is set equal to $(1 \ll (8 + \text{bit_depth_luma_minus8})) - 1$, where bit_depth_luma_minus8 is the value included in or inferred for the active SPS of the layer with nuh_layer_id equal to targetLayerId. The value of

depth_representation_type shall be in the range of 0 to 3, inclusive, in bitstreams conforming to this version of this Specification. The values of 4 to 15, inclusive, for depth_representation_type are reserved for future use by ITU-T | ISO/IEC. Although the value of depth_representation_type is required to be in the range of 0 to 3, inclusive, in this version of this Specification, decoders shall allow values of depth_representation_type in the range of 4 to 15, inclusive, to appear in the syntax. Decoders conforming to this version of this Specification shall ignore all data that follow a value of depth_representation_type in the range of 4 to 15, inclusive, in the depth representation information SEI message.

Table G.3 – Definition of depth_representation_type

depth_representation_type	Interpretation
0	Each decoded luma sample value of an auxiliary picture represents an inverse of Z value that is uniformly quantized into the range of 0 to maxVal, inclusive. When z_far_flag is equal to 1, the luma sample value equal to 0 represents the inverse of ZFar (specified below). When z_near_flag is equal to 1, the luma sample value equal to maxVal represents the inverse of ZNear (specified below).
1	Each decoded luma sample value of an auxiliary picture represents disparity that is uniformly quantized into the range of 0 to maxVal, inclusive. When d_min_flag is equal to 1, the luma sample value equal to 0 represents DMin (specified below). When d_max_flag is equal to 1, the luma sample value equal to maxVal represents DMax (specified below).
2	Each decoded luma sample value of an auxiliary picture represents a Z value uniformly quantized into the range of 0 to maxVal, inclusive. When z_far_flag is equal to 1, the luma sample value equal to 0 corresponds to ZFar (specified below). When z_near_flag is equal to 1, the luma sample value equal to maxVal represents ZNear (specified below).
3	Each decoded luma sample value of an auxiliary picture represents a non-linearly mapped disparity, normalized in range from 0 to maxVal, as specified by depth_nonlinear_representation_num_minus1 and depth_nonlinear_representation_model[i]. When d_min_flag is equal to 1, the luma sample value equal to 0 represents DMin (specified below). When d_max_flag is equal to 1, the luma sample value equal to maxVal represents DMax (specified below).
4..15	Reserved

disparity_ref_view_id specifies the ViewId value for which the disparity values are derived. The value of disparity_ref_view_id shall be in the range of 0 to 1 023, inclusive.

NOTE 1 – disparity_ref_view_id is present only if d_min_flag is equal to 1 or d_max_flag is equal to 1 and is useful for depth_representation_type values equal to 1 and 3.

The variables in the x column of Table G.4 are derived from the respective variables in the s, e, n and v columns of Table G.4 as follows:

- If the value of e is in the range of 0 to 127, exclusive, x is set equal to $(-1)^s * 2^{e-31} * (1 + n \div 2^v)$.
- Otherwise (e is equal to 0), x is set equal to $(-1)^s * 2^{-(30+v)} * n$.

NOTE 1 – The above specification is similar to that found in IEC 60559:1989.

Table G.4 – Association between depth parameter variables and syntax elements

x	S	e	n	v
ZNear	ZNearSign	ZNearExp	ZNearMantissa	ZNearManLen
ZFar	ZFarSign	ZFarExp	ZFarMantissa	ZFarManLen
DMax	DMaxSign	DMaxExp	DMaxMantissa	DMaxManLen
DMin	DMinSign	DMinExp	DMinMantissa	DMinManLen

The DMin and DMax values, when present, are specified in units of a luma sample width of the coded picture with ViewId equal to ViewId of the auxiliary picture.

The units for the ZNear and ZFar values, when present, are identical but unspecified.

depth_nonlinear_representation_num_minus1 plus 2 specifies the number of piece-wise linear segments for mapping of depth values to a scale that is uniformly quantized in terms of disparity. The value of **depth_nonlinear_representation_num_minus1** shall be in the range of 0 to 62, inclusive.

depth_nonlinear_representation_model[i] for *i* ranging from 0 to **depth_nonlinear_representation_num_minus1 + 2**, inclusive, specify the piece-wise linear segments for mapping of decoded luma sample values of an auxiliary picture to a scale that is uniformly quantized in terms of disparity. The value of **depth_nonlinear_representation_model[i]** shall be in the range of 0 to 65 535, inclusive. The values of **depth_nonlinear_representation_model[0]** and **depth_nonlinear_representation_model[depth_nonlinear_representation_num_minus1 + 2]** are both inferred to be equal to 0.

NOTE 2 – When **depth_representation_type** is equal to 3, an auxiliary picture contains non-linearly transformed depth samples. The variable **DepthLUT[i]**, as specified below, is used to transform decoded depth sample values from the non-linear representation to the linear representation, i.e., uniformly quantized disparity values. The shape of this transform is defined by means of line-segment approximation in two-dimensional linear-disparity-to-non-linear-disparity space. The first (0, 0) and the last (**maxVal**, **maxVal**) nodes of the curve are predefined. Positions of additional nodes are transmitted in form of deviations (**depth_nonlinear_representation_model[i]**) from the straight-line curve. These deviations are uniformly distributed along the whole range of 0 to **maxVal**, inclusive, with spacing depending on the value of **nonlinear_depth_representation_num_minus1**.

The variable **DepthLUT[i]** for *i* in the range of 0 to **maxVal**, inclusive, is specified as follows:

```
for( k = 0; k <= depth_nonlinear_representation_num_minus1 + 1; k++ ) {
    pos1 = ( maxVal * k ) / (depth_nonlinear_representation_num_minus1 + 2 )
    dev1 = depth_nonlinear_representation_model[ k ]
    pos2 = ( maxVal * ( k + 1 ) ) / (depth_nonlinear_representation_num_minus1 + 2 )
    dev2 = depth_nonlinear_representation_model[ k + 1 ]
    x1 = pos1 - dev1
    y1 = pos1 + dev1
    x2 = pos2 - dev2
    y2 = pos2 + dev2

    for( x = Max( x1, 0 ); x <= Min( x2, maxVal ); x++ )
        DepthLUT[ x ] = Clip3( 0, maxVal, Round( (( x - x1 ) * ( y2 - y1 )) ÷ ( x2 - x1 ) + y1 ) )
}
```

(G-10)

When **depth_representation_type** is equal to 3, **DepthLUT[dS]** for all decoded luma sample values **dS** of an auxiliary picture in the range of 0 to **maxVal**, inclusive, represents disparity that is uniformly quantized into the range of 0 to **maxVal**, inclusive.

G.14.3.3.2 Depth representation information element semantics

The syntax structure specifies the value of an element in the depth representation information SEI message.

The **depth_rep_info_element(OutSign, OutExp, OutMantissa, OutManLen)** syntax structure sets the values of the **OutSign**, **OutExp**, **OutMantissa** and **OutManLen** variables that represent a floating-point value. When the syntax structure is included in another syntax structure, the variable names **OutSign**, **OutExp**, **OutMantissa** and **OutManLen** are to be interpreted as being replaced by the variable names used when the syntax structure is included.

da_sign_flag equal to 0 indicates that the sign of the floating-point value is positive. **da_sign_flag** equal to 1 indicates that the sign is negative. The variable **OutSign** is set equal to **da_sign_flag**.

da_exponent specifies the exponent of the floating-point value. The value of **da_exponent** shall be in the range of 0 to $2^7 - 2$, inclusive. The value $2^7 - 1$ is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value $2^7 - 1$ as indicating an unspecified value. The variable **OutExp** is set equal to **da_exponent**.

da_mantissa_len_minus1 plus 1 specifies the number of bits in the **da_mantissa** syntax element. The variable **OutManLen** is set equal to **da_mantissa_len_minus1 + 1**.

da_mantissa specifies the mantissa of the floating-point value. The variable **OutMantissa** is set equal to **da_mantissa**.

G.14.3.4 Multiview scene information SEI message semantics

The multiview scene information SEI message indicates the minimum disparity and the maximum disparity among multiple views in an access unit. The minimum disparity and the maximum disparity could be used for processing the decoded views prior to rendering on a 3D display. When present, the multiview scene information SEI message shall be associated with an IRAP access unit. The information signalled in the SEI message applies to the coded video sequence. If the SEI message is not contained within a scalable nesting SEI message, it applies to the views with **nuh_layer_id** greater than or equal to the **nuh_layer_id** value of the SEI NAL unit that contains the SEI message. Otherwise (the SEI message is contained within a scalable nesting SEI message), the SEI message applies to the view with **nuh_layer_id** values identified in the scalable nesting SEI message. The views to which the SEI message applies are referred to as applicable views below.

The actual minimum disparity value may be greater than the one signalled in the multiview scene information SEI message and the actual maximum disparity value may be less than the one signalled in the multiview scene information SEI message, due to that some views in the coded video sequence may have been removed from the original bitstream to produce an extracted sub-bitstream, for example according to the process specified in clause 10.

Let x_R be a luma sample position within a luma sample array of the right-side picture of any spatially adjacent views among the applicable views in an access unit. Let x_L be the respective luma sample position within a luma sample array of the left-side picture of the same spatially adjacent view such that sample in the luma sample position x_L in the left-side view represents the same content as luma sample position x_R in the right-side picture. When $\text{pic_width_in_luma_samples}$ for the left-side picture, picWidthL , is not equal to $\text{pic_width_in_luma_samples}$ for the right-side picture, picWidthR , x_L is normalized to the horizontal luma sample resolution of the right-side picture, i.e., x_L is set equal to $\text{Round}(x_L * (\text{picWidthR} \div \text{picWidthL}))$. The disparity between x_R and x_L is specified to be equal to $(x_R - x_L)$. The maximum disparity between two pictures is defined to be the maximum of the disparity between any sample position pairs x_R and x_L . The minimum disparity between two pictures is defined to be the minimum of the disparity between any sample position pairs x_R and x_L .

min_disparity specifies the minimum disparity, in units of luma samples, between pictures of any spatially adjacent views among the applicable views in an access unit. The value of **min_disparity** shall be in the range of $-1\,024$ to $1\,023$, inclusive.

max_disparity_range specifies that the maximum disparity, in units of luma samples, between pictures of any spatially adjacent views among the applicable views in an access unit. The value of **max_disparity_range** shall be in the range of 0 to 2047, inclusive.

NOTE – The minimum disparity and the maximum disparity depend on the baseline distance between spatially adjacent views and the spatial resolution of each view. Therefore, if either the number of views or spatial resolution is changed, the minimum disparity and the maximum disparity should also be changed accordingly.

G.14.3.5 Multiview acquisition information SEI message semantics

The multiview acquisition information SEI message specifies various parameters of the acquisition environment. Specifically, intrinsic and extrinsic camera parameters are specified. These parameters could be used for processing the decoded views prior to rendering on a 3D display.

The following semantics apply separately to each nuh_layer_id `targetLayerId` among the nuh_layer_id values to which the multiview acquisition information SEI message applies as specified in clause D.3.1.

When present, the multiview acquisition information SEI message that applies to the current layer shall be included in an access unit that contains an IRAP picture that is the first picture of a CLVS of the current layer. The information signalled in the SEI message applies to the CLVS.

When the multiview acquisition information SEI message is included in a scalable nesting SEI message, the syntax elements `bitstream_subset_flag`, `nesting_op_flag` and `all_layers_flag` in the scalable nesting SEI message shall be equal to 0.

The variable `numViewsMinus1` is derived as follows:

- If the multiview acquisition information SEI message is not included in a scalable nesting SEI message, `numViewsMinus1` is set equal to 0.
- Otherwise (the multiview acquisition information SEI message is included in a scalable nesting SEI message), `numViewsMinus1` is set equal to `nesting_num_layers_minus1`.

Some of the views for which the multiview acquisition information is included in a multiview acquisition information SEI message may not be present.

In the semantics below, index i refers to the syntax elements and variables that apply to the layer with nuh_layer_id equal to `nestingLayerIdList[0][i]`.

The extrinsic camera parameters are specified according to a right-handed coordinate system, where the upper left corner of the image is the origin, i.e., the $(0, 0)$ coordinate, with the other corners of the image having non-negative coordinates. With these specifications, a 3-dimensional world point, $wP = [x\ y\ z]$ is mapped to a 2-dimensional camera point, $cP[i] = [u\ v\ 1]$, for the i -th camera according to:

$$s * cP[i] = A[i] * R^{-1}[i] * (wP - T[i]) \quad (G-11)$$

where $A[i]$ denotes the intrinsic camera parameter matrix, $R^{-1}[i]$ denotes the inverse of the rotation matrix $R[i]$, $T[i]$ denotes the translation vector and s (a scalar value) is an arbitrary scale factor chosen to make the third coordinate of $cP[i]$ equal to 1. The elements of $A[i]$, $R[i]$ and $T[i]$ are determined according to the syntax elements signalled in this SEI message and as specified below.

intrinsic_param_flag equal to 1 indicates the presence of intrinsic camera parameters. **intrinsic_param_flag** equal to 0

indicates the absence of intrinsic camera parameters.

extrinsic_param_flag equal to 1 indicates the presence of extrinsic camera parameters. **extrinsic_param_flag** equal to 0 indicates the absence of extrinsic camera parameters.

intrinsic_params_equal_flag equal to 1 indicates that the intrinsic camera parameters are equal for all cameras and only one set of intrinsic camera parameters is present. **intrinsic_params_equal_flag** equal to 0 indicates that the intrinsic camera parameters are different for each camera and that a set of intrinsic camera parameters is present for each camera.

prec_focal_length specifies the exponent of the maximum allowable truncation error for **focal_length_x[i]** and **focal_length_y[i]** as given by $2^{-\text{prec_focal_length}}$. The value of **prec_focal_length** shall be in the range of 0 to 31, inclusive.

prec_principal_point specifies the exponent of the maximum allowable truncation error for **principal_point_x[i]** and **principal_point_y[i]** as given by $2^{-\text{prec_principal_point}}$. The value of **prec_principal_point** shall be in the range of 0 to 31, inclusive.

prec_skew_factor specifies the exponent of the maximum allowable truncation error for skew factor as given by $2^{-\text{prec_skew_factor}}$. The value of **prec_skew_factor** shall be in the range of 0 to 31, inclusive.

sign_focal_length_x[i] equal to 0 indicates that the sign of the focal length of the i-th camera in the horizontal direction is positive. **sign_focal_length_x[i]** equal to 1 indicates that the sign is negative.

exponent_focal_length_x[i] specifies the exponent part of the focal length of the i-th camera in the horizontal direction. The value of **exponent_focal_length_x[i]** shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value 63 as indicating an unspecified focal length.

mantissa_focal_length_x[i] specifies the mantissa part of the focal length of the i-th camera in the horizontal direction. The length of the **mantissa_focal_length_x[i]** syntax element in units of bits is variable and determined as follows:

- If **exponent_focal_length_x[i]** is equal to 0, the length is $\text{Max}(0, \text{prec_focal_length} - 30)$.
- Otherwise (**exponent_focal_length_x[i]** is in the range of 0 to 63, exclusive), the length is $\text{Max}(0, \text{exponent_focal_length_x}[i] + \text{prec_focal_length} - 31)$.

sign_focal_length_y[i] equal to 0 indicates that the sign of the focal length of the i-th camera in the vertical direction is positive. **sign_focal_length_y[i]** equal to 1 indicates that the sign is negative.

exponent_focal_length_y[i] specifies the exponent part of the focal length of the i-th camera in the vertical direction. The value of **exponent_focal_length_y[i]** shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value 63 as indicating an unspecified focal length.

mantissa_focal_length_y[i] specifies the mantissa part of the focal length of the i-th camera in the vertical direction.

The length of the **mantissa_focal_length_y[i]** syntax element in units of bits is variable and determined as follows:

- If **exponent_focal_length_y[i]** is equal to 0, the length is $\text{Max}(0, \text{prec_focal_length} - 30)$.
- Otherwise (**exponent_focal_length_y[i]** is in the range of 0 to 63, exclusive), the length is $\text{Max}(0, \text{exponent_focal_length_y}[i] + \text{prec_focal_length} - 31)$.

sign_principal_point_x[i] equal to 0 indicates that the sign of the principal point of the i-th camera in the horizontal direction is positive. **sign_principal_point_x[i]** equal to 1 indicates that the sign is negative.

exponent_principal_point_x[i] specifies the exponent part of the principal point of the i-th camera in the horizontal direction. The value of **exponent_principal_point_x[i]** shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value 63 as indicating an unspecified principal point.

mantissa_principal_point_x[i] specifies the mantissa part of the principal point of the i-th camera in the horizontal direction. The length of the **mantissa_principal_point_x[i]** syntax element in units of bits is variable and is determined as follows:

- If **exponent_principal_point_x[i]** is equal to 0, the length is $\text{Max}(0, \text{prec_principal_point} - 30)$.
- Otherwise (**exponent_principal_point_x[i]** is in the range of 0 to 63, exclusive), the length is $\text{Max}(0, \text{exponent_principal_point_x}[i] + \text{prec_principal_point} - 31)$.

sign_principal_point_y[i] equal to 0 indicates that the sign of the principal point of the i-th camera in the vertical direction is positive. **sign_principal_point_y[i]** equal to 1 indicates that the sign is negative.

exponent_principal_point_y[i] specifies the exponent part of the principal point of the i-th camera in the vertical direction. The value of **exponent_principal_point_y[i]** shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value 63 as indicating an unspecified principal point.

mantissa_principal_point_y[i] specifies the mantissa part of the principal point of the i-th camera in the vertical direction. The length of the mantissa_principal_point_y[i] syntax element in units of bits is variable and is determined as follows:

- If exponent_principal_point_y[i] is equal to 0, the length is $\text{Max}(0, \text{prec_principal_point} - 30)$.
- Otherwise (exponent_principal_point_y[i] is in the range of 0 to 63, exclusive), the length is $\text{Max}(0, \text{exponent_principal_point_y}[i] + \text{prec_principal_point} - 31)$.

sign_skew_factor[i] equal to 0 indicates that the sign of the skew factor of the i-th camera is positive.

sign_skew_factor[i] equal to 1 indicates that the sign is negative.

exponent_skew_factor[i] specifies the exponent part of the skew factor of the i-th camera. The value of exponent_skew_factor[i] shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value 63 as indicating an unspecified skew factor.

mantissa_skew_factor[i] specifies the mantissa part of the skew factor of the i-th camera. The length of the mantissa_skew_factor[i] syntax element in units of bits is variable and determined as follows:

- If exponent_skew_factor[i] is equal to 0, the length is $\text{Max}(0, \text{prec_skew_factor} - 30)$.
- Otherwise (exponent_skew_factor[i] is in the range of 0 to 63, exclusive), the length is $\text{Max}(0, \text{exponent_skew_factor}[i] + \text{prec_skew_factor} - 31)$.

The intrinsic matrix $A[i]$ for i-th camera is represented by

$$\begin{bmatrix} \text{focalLengthX}[i] & \text{skewFactor}[i] & \text{principalPointX}[i] \\ 0 & \text{focalLengthY}[i] & \text{principalPointY}[i] \\ 0 & 0 & 1 \end{bmatrix} \quad (\text{G-12})$$

prec_rotation_param specifies the exponent of the maximum allowable truncation error for $r[i][j][k]$ as given by $2^{-\text{prec_rotation_param}}$. The value of prec_rotation_param shall be in the range of 0 to 31, inclusive.

prec_translation_param specifies the exponent of the maximum allowable truncation error for $t[i][j]$ as given by $2^{-\text{prec_translation_param}}$. The value of prec_translation_param shall be in the range of 0 to 31, inclusive.

sign_r[i][j][k] equal to 0 indicates that the sign of (j, k) component of the rotation matrix for the i-th camera is positive. **sign_r[i][j][k]** equal to 1 indicates that the sign is negative.

exponent_r[i][j][k] specifies the exponent part of (j, k) component of the rotation matrix for the i-th camera. The value of exponent_r[i][j][k] shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value 63 as indicating an unspecified rotation matrix.

mantissa_r[i][j][k] specifies the mantissa part of (j, k) component of the rotation matrix for the i-th camera. The length of the mantissa_r[i][j][k] syntax element in units of bits is variable and determined as follows:

- If exponent_r[i] is equal to 0, the length is $\text{Max}(0, \text{prec_rotation_param} - 30)$.
- Otherwise (exponent_r[i] is in the range of 0 to 63, exclusive), the length is $\text{Max}(0, \text{exponent_r}[i] + \text{prec_rotation_param} - 31)$.

The rotation matrix $R[i]$ for i-th camera is represented as follows:

$$\begin{bmatrix} rE[i][0][0] & rE[i][0][1] & rE[i][0][2] \\ rE[i][1][0] & rE[i][1][1] & rE[i][1][2] \\ rE[i][2][0] & rE[i][2][1] & rE[i][2][2] \end{bmatrix} \quad (\text{G-13})$$

sign_t[i][j] equal to 0 indicates that the sign of the j-th component of the translation vector for the i-th camera is positive. **sign_t[i][j]** equal to 1 indicates that the sign is negative.

exponent_t[i][j] specifies the exponent part of the j-th component of the translation vector for the i-th camera. The value of exponent_t[i][j] shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. Decoders shall treat the value 63 as indicating an unspecified translation vector.

mantissa_t[i][j] specifies the mantissa part of the j-th component of the translation vector for the i-th camera. The length v of the mantissa_t[i][j] syntax element in units of bits is variable and is determined as follows:

- If $\text{exponent_t}[i]$ is equal to 0, the length v is set equal to $\text{Max}(0, \text{prec_translation_param} - 30)$.
- Otherwise ($0 < \text{exponent_t}[i] < 63$), the length v is set equal to $\text{Max}(0, \text{exponent_t}[i] + \text{prec_translation_param} - 31)$.

The translation vector $T[i]$ for the i -th camera is represented by:

$$\begin{bmatrix} tE[i][0] \\ tE[i][1] \\ tE[i][2] \end{bmatrix} \quad (\text{G-14})$$

The association between the camera parameter variables and corresponding syntax elements is specified by Table G.5. Each component of the intrinsic and rotation matrices and the translation vector is obtained from the variables specified in Table G.5 as the variable x computed as follows:

- If e is in the range of 0 to 63, exclusive, x is set equal to $(-1)^s * 2^{e-31} * (1 + n \div 2^v)$.
- Otherwise (e is equal to 0), x is set equal to $(-1)^s * 2^{-(30+v)} * n$.

NOTE – The above specification is similar to that found in IEC 60559:1989.

Table G.5 – Association between camera parameter variables and syntax elements.

x	s	e	n
focalLengthX [i]	sign_focal_length_x[i]	exponent_focal_length_x[i]	mantissa_focal_length_x[i]
focalLengthY [i]	sign_focal_length_y[i]	exponent_focal_length_y[i]	mantissa_focal_length_y[i]
principalPointX [i]	sign_principal_point_x[i]	exponent_principal_point_x[i]	mantissa_principal_point_x[i]
principalPointY [i]	sign_principal_point_y[i]	exponent_principal_point_y[i]	mantissa_principal_point_y[i]
skewFactor [i]	sign_skew_factor[i]	exponent_skew_factor[i]	mantissa_skew_factor[i]
rE [i][j][k]	sign_r[i][j][k]	exponent_r[i][j][k]	mantissa_r[i][j][k]
tE [i][j]	sign_t[i][j]	exponent_t[i][j]	mantissa_t[i][j]

G.14.3.6 Multiview view position SEI message semantics

The multiview view position SEI message specifies the relative view position along a single horizontal axis of views within a CVS. When present, the multiview view position SEI message shall be associated with an IRAP access unit. The information signalled in this SEI message applies to the entire CVS.

num_views_minus1 plus 1 shall be equal to NumViews derived from the active VPS for the CVS. The value of **num_views_minus1** shall be in the range of 0 to 62, inclusive.

view_position[i] indicates the order of the view with ViewOrderIdx equal to i among all the views from left to right for the purpose of display, with the order for the left-most view being equal to 0 and the value of the order increasing by 1 for next view from left to right. The value of **view_position**[i] shall be in the range of 0 to 62, inclusive.

G.15 Video usability information

The specifications in clause F.15 and its subclauses apply.

Annex H

Scalable high efficiency video coding

(This annex forms an integral part of this Recommendation | International Standard.)

H.1 Scope

This annex specifies syntax, semantics and decoding processes for scalable high efficiency video coding that use the syntax, semantics, and decoding process specified in clauses 2-10 and Annexes A-F. This annex also specifies profiles, tier and levels for scalable high efficiency video coding.

H.2 Normative references

The list of normative references in clause F.2 applies.

H.3 Definitions

The specifications in clause F.3 and its subclauses apply.

H.4 Abbreviations

The specifications in clause F.4 apply.

H.5 Conventions

The specifications in clause F.5 apply.

H.6 Bitstream and picture formats, partitionings, scanning processes, and neighbouring relationships

The specifications in clause F.6 apply.

H.7 Syntax and semantics

The specifications in clause F.7 and its subclauses apply.

H.8 Decoding processes

H.8.1 General decoding process

H.8.1.1 General

The specifications of clause F.8.1.1 apply.

H.8.1.2 Decoding process for a coded picture with `nuh_layer_id` greater than 0

The decoding process for the current picture CurrPic is as follows:

1. The decoding of NAL units is specified in clause H.8.2.
2. The processes in clauses H.8.1.3 and H.8.3.4 specify the following decoding processes using syntax elements in the slice segment layer and above:
 - At the beginning of the decoding process for the first slice of the current picture, the process specified in clause H.8.1.3 is invoked.
 - At the beginning of the decoding process for each P or B slice, the decoding process for reference picture lists construction specified in clause H.8.3.4 is invoked for derivation of reference picture list 0 (RefPicList0), and when decoding a B slice, reference picture list 1 (RefPicList1).
3. The processes in clauses H.8.4, H.8.5, H.8.6 and H.8.7 specify decoding processes using syntax elements in all syntax structure layers. It is a requirement of bitstream conformance that the coded slices of the picture shall contain slice segment data for every CTU of the picture, such that the division of the picture into slices, the division of the slices into slice segments, and the division of the slice segments into CTUs each form a partitioning of the picture.

H.8.1.3 Decoding process for inter-layer reference picture set

Outputs of this process are updated lists of inter-layer reference pictures RefPicSetInterLayer0 and RefPicSetInterLayer1 and the variables NumActiveRefLayerPics0 and NumActiveRefLayerPics1.

The variable currLayerId is set equal to nuh_layer_id of the current picture.

The variables NumRefLayerPicsProcessing, NumRefLayerPicsSampleProcessing and NumRefLayerPicsMotionProcessing are set equal to 0.

The lists RefPicSetInterLayer0 and RefPicSetInterLayer1 are first emptied, NumActiveRefLayerPics0 and NumActiveRefLayerPics1 are set equal to 0 and the following applies:

```
for( i = 0; i < NumActiveRefLayerPics; i++ ) {
    refPicSet0Flag =
        ( ( ViewId[ currLayerId ] <= ViewId[ 0 ] && ViewId[ currLayerId ] <=
ViewId[ RefPicLayerId[ i ] ] ) ||
        ( ViewId[ currLayerId ] >= ViewId[ 0 ] && ViewId[ currLayerId ] >=
ViewId[ RefPicLayerId[ i ] ] ) )
    if( there is a picture picX in the DPB that is in the same access unit as the current picture and has
        nuh_layer_id equal to RefPicLayerId[ i ] ) {
        an inter-layer reference picture ilRefPic is derived by invoking the process specified in clause
H.8.1.4
        with picX and RefPicLayerId[ i ] given as inputs
        if( refPicSet0Flag ) {
            (H-1)
            RefPicSetInterLayer0[ NumActiveRefLayerPics0 ] = ilRefPic
            RefPicSetInterLayer0[ NumActiveRefLayerPics0++ ] is marked as "used for long-term
reference"
        } else {
            RefPicSetInterLayer1[ NumActiveRefLayerPics1 ] = ilRefPic
            RefPicSetInterLayer1[ NumActiveRefLayerPics1++ ] is marked as "used for long-term
reference"
        }
    } else {
        if( refPicSet0Flag )
            RefPicSetInterLayer0[ NumActiveRefLayerPics0++ ] = "no reference picture"
        else
            RefPicSetInterLayer1[ NumActiveRefLayerPics1++ ] = "no reference picture"
    }
}
```

There shall be no entry equal to "no reference picture" in RefPicSetInterLayer0 or RefPicSetInterLayer1.

There shall be no picture that has discardable_flag equal to 1 in RefPicSetInterLayer0 or RefPicSetInterLayer1.

NOTE 1 – For the profiles defined in this annex, RefPicSetInterLayer1 is always empty since the value of ViewId[i] is equal to zero for all layers.

If the current picture is a RADL picture, there shall be no entry in the RefPicSetInterLayer0 or RefPicSetInterLayer1 that is a RASL picture.

NOTE 2 – An access unit may contain both RASL and RADL pictures.

H.8.1.4 Derivation process for inter-layer reference pictures

H.8.1.4.1 General

Inputs to this process are:

- a decoded direct reference layer picture rLPic,
- a variable rLId specifying the value of nuh_layer_id of the direct reference layer picture.

Output of this process is the inter-layer reference picture ilRefPic.

The variables `PicWidthInSamplesCurrY`, `PicHeightInSamplesCurrY`, `BitDepthCurrY`, `BitDepthCurrC`, `SubWidthCurrC` and `SubHeightCurrC` are set equal to `pic_width_in_luma_samples`, `pic_height_in_luma_samples`, `BitDepthY`, `BitDepthC`, `SubWidthC` and `SubHeightC` of the current layer, respectively.

The variables `PicWidthInSamplesRefLayerY` and `PicHeightInSamplesRefLayerY` are set equal to the width and height of the decoded direct reference layer picture `rlPic` in units of luma samples, respectively. The variables `BitDepthRefLayerY`, `BitDepthRefLayerC`, `SubWidthRefLayerC` and `SubHeightRefLayerC` are set equal to the values of `BitDepthY`, `BitDepthC`, `SubWidthC` and `SubHeightC` of the direct reference layer picture `rlPic`, respectively.

NOTE – This clause and its subclauses support all possible values of `SubWidthCurrC`, `SubHeightCurrC`, `SubWidthRefLayerC` and `SubHeightRefLayerC`. When the value of `chroma_format_idc` of the current layer and the value of `chroma_format_idc` of the direct reference layer are both equal to 1, the values of `SubWidthCurrC`, `SubHeightCurrC`, `SubWidthRefLayerC` and `SubHeightRefLayerC` are all equal to 2, and the resampling process of picture sample values in clause H.8.1.4.2 and the colour mapping process of picture sample values in clause H.8.1.4.4 can be simplified.

The variables `RefLayerRegionLeftOffset`, `RefLayerRegionTopOffset`, `RefLayerRegionRightOffset` and `RefLayerRegionBottomOffset` are derived as follows:

$$\text{RefLayerRegionLeftOffset} = \text{ref_region_left_offset}[\text{rLId}] * \text{SubWidthRefLayerC} \quad (\text{H-2})$$

$$\text{RefLayerRegionTopOffset} = \text{ref_region_top_offset}[\text{rLId}] * \text{SubHeightRefLayerC} \quad (\text{H-3})$$

$$\text{RefLayerRegionRightOffset} = \text{ref_region_right_offset}[\text{rLId}] * \text{SubWidthRefLayerC} \quad (\text{H-4})$$

$$\text{RefLayerRegionBottomOffset} = \text{ref_region_bottom_offset}[\text{rLId}] * \text{SubHeightRefLayerC} \quad (\text{H-5})$$

The variables `RefLayerRegionWidthInSamplesY` and `RefLayerRegionHeightInSamplesY` are the width and height of the reference region in the decoded direct reference layer picture `rlPic` in units of luma samples, respectively, and are derived as follows:

$$\text{RefLayerRegionWidthInSamplesY} = \text{PicWidthInSamplesRefLayerY} - \text{RefLayerRegionLeftOffset} - \text{RefLayerRegionRightOffset} \quad (\text{H-6})$$

$$\text{RefLayerRegionHeightInSamplesY} = \text{PicHeightInSamplesRefLayerY} - \text{RefLayerRegionTopOffset} - \text{RefLayerRegionBottomOffset} \quad (\text{H-7})$$

The variables `PicWidthInSamplesCurrC`, `PicHeightInSamplesCurrC`, `PicWidthInSamplesRefLayerC` and `PicHeightInSamplesRefLayerC` are derived as follows:

$$\text{PicWidthInSamplesCurrC} = \text{PicWidthInSamplesCurrY} / \text{SubWidthCurrC} \quad (\text{H-8})$$

$$\text{PicHeightInSamplesCurrC} = \text{PicHeightInSamplesCurrY} / \text{SubHeightCurrC} \quad (\text{H-9})$$

$$\text{PicWidthInSamplesRefLayerC} = \text{PicWidthInSamplesRefLayerY} / \text{SubWidthRefLayerC} \quad (\text{H-10})$$

$$\text{PicHeightInSamplesRefLayerC} = \text{PicHeightInSamplesRefLayerY} / \text{SubHeightRefLayerC} \quad (\text{H-11})$$

The variables `ScaledRefLayerLeftOffset`, `ScaledRefLayerTopOffset`, `ScaledRefLayerRightOffset` and `ScaledRefLayerBottomOffset` are derived as follows:

$$\text{ScaledRefLayerLeftOffset} = \text{scaled_ref_layer_left_offset}[\text{rLId}] * \text{SubWidthCurrC} \quad (\text{H-12})$$

$$\text{ScaledRefLayerTopOffset} = \text{scaled_ref_layer_top_offset}[\text{rLId}] * \text{SubHeightCurrC} \quad (\text{H-13})$$

$$\text{ScaledRefLayerRightOffset} = \text{scaled_ref_layer_right_offset}[\text{rLId}] * \text{SubWidthCurrC} \quad (\text{H-14})$$

$$\text{ScaledRefLayerBottomOffset} = \text{scaled_ref_layer_bottom_offset}[\text{rLId}] * \text{SubHeightCurrC} \quad (\text{H-15})$$

The variables `ScaledRefRegionWidthInSamplesY` and `ScaledRefRegionHeightInSamplesY` are derived as follows:

$$\text{ScaledRefRegionWidthInSamplesY} = \text{PicWidthInSamplesCurrY} - \text{ScaledRefLayerLeftOffset} - \text{ScaledRefLayerRightOffset} \quad (\text{H-16})$$

$$\text{ScaledRefRegionHeightInSamplesY} = \text{PicHeightInSamplesCurrY} - \text{ScaledRefLayerTopOffset} - \text{ScaledRefLayerBottomOffset} \quad (\text{H-17})$$

The variables $\text{SpatialScaleFactorHorY}$, $\text{SpatialScaleFactorVerY}$, $\text{SpatialScaleFactorHorC}$ and $\text{SpatialScaleFactorVerC}$ are derived as follows:

$$\text{SpatialScaleFactorHorY} = ((\text{RefLayerRegionWidthInSamplesY} \ll 16) + (\text{ScaledRefRegionWidthInSamplesY} \gg 1)) / \text{ScaledRefRegionWidthInSamplesY} \quad (\text{H-18})$$

$$\text{SpatialScaleFactorVerY} = ((\text{RefLayerRegionHeightInSamplesY} \ll 16) + (\text{ScaledRefRegionHeightInSamplesY} \gg 1)) / \text{ScaledRefRegionHeightInSamplesY} \quad (\text{H-19})$$

$$\text{SpatialScaleFactorHorC} = (((\text{RefLayerRegionWidthInSamplesY} / \text{SubWidthRefLayerC}) \ll 16) + ((\text{ScaledRefRegionWidthInSamplesY} / \text{SubWidthCurrC}) \gg 1)) / (\text{ScaledRefRegionWidthInSamplesY} / \text{SubWidthCurrC}) \quad (\text{H-20})$$

$$\begin{aligned} \text{SpatialScaleFactorVerC} = & (((\text{RefLayerRegionHeightInSamplesY} / \text{SubHeightRefLayerC}) \ll 16) + \\ & ((\text{ScaledRefRegionHeightInSamplesY} / \text{SubHeightCurrC}) \gg 1)) / (\text{ScaledRefRegionHeightInSamplesY} / \text{SubHeightCurrC}) \end{aligned} \quad (\text{H-21})$$

The variables PhaseHorY , PhaseVerY , PhaseHorC and PhaseVerC are set as follows:

$$\text{PhaseHorY} = \text{phase_hor_luma}[\text{rLId}] \quad (\text{H-22})$$

$$\text{PhaseVerY} = \text{phase_ver_luma}[\text{rLId}] \quad (\text{H-23})$$

$$\text{PhaseHorC} = \text{phase_hor_chroma_plus8}[\text{rLId}] - 8 \quad (\text{H-24})$$

$$\text{PhaseVerC} = \text{phase_ver_chroma_plus8}[\text{rLId}] - 8 \quad (\text{H-25})$$

It is a requirement of bitstream conformance that BitDepthRefLayerY shall be less than or equal to BitDepthCurrY and BitDepthRefLayerC shall be less than or equal to BitDepthCurrC .

It is a requirement of bitstream conformance that the values of $\text{RefLayerRegionWidthInSamplesY}$, $\text{RefLayerRegionHeightInSamplesY}$, $\text{ScaledRefRegionWidthInSamplesY}$ and $\text{ScaledRefRegionHeightInSamplesY}$ shall be greater than 0.

It is a requirement of bitstream conformance that $\text{ScaledRefRegionWidthInSamplesY}$ shall be greater than or equal to $\text{RefLayerRegionWidthInSamplesY}$ and $\text{ScaledRefRegionHeightInSamplesY}$ shall be greater than or equal to $\text{RefLayerRegionHeightInSamplesY}$.

It is a requirement of bitstream conformance that, when $\text{ScaledRefRegionWidthInSamplesY}$ is equal to $\text{RefLayerRegionWidthInSamplesY}$, PhaseHorY shall be equal to 0, when $\text{ScaledRefRegionWidthInSamplesC}$ is equal to $\text{RefLayerRegionWidthInSamplesC}$, PhaseHorC shall be equal to 0, when $\text{ScaledRefRegionHeightInSamplesY}$ is equal to $\text{RefLayerRegionHeightInSamplesY}$, PhaseVerY shall be equal to 0, and when $\text{ScaledRefRegionHeightInSamplesC}$ is equal to $\text{RefLayerRegionHeightInSamplesC}$, PhaseVerC shall be equal to 0.

The inter-layer reference picture ilRefPic is derived as follows:

- The variables $\text{sampleProcessingFlag}$ and $\text{motionProcessingFlag}$ are initialized to 0.
- The variable $\text{equalPictureSizeAndOffsetFlag}$ is derived as follows:
 - If all of the following conditions are true, $\text{equalPictureSizeAndOffsetFlag}$ is set equal to 1:

- PicWidthInSamplesCurrY is equal to PicWidthInSamplesRefLayerY
- PicHeightInSamplesCurrY is equal to PicHeightInSamplesRefLayerY
- ScaledRefLayerLeftOffset is equal to RefLayerRegionLeftOffset
- ScaledRefLayerTopOffset is equal to RefLayerRegionTopOffset
- ScaledRefLayerRightOffset is equal to RefLayerRegionRightOffset
- ScaledRefLayerBottomOffset is equal to RefLayerRegionBottomOffset
- PhaseHorY, PhaseVerY, PhaseHorC and PhaseVerC are all equal to 0
- Otherwise, equalPictureSizeAndOffsetFlag is set equal to 0.
- The variable currColourMappingEnableFlag is derived as follows:
 - If colour_mapping_enabled_flag is equal to 1 and if there exists a value of i, with i in the range of 0 to num_cm_ref_layers_minus1, inclusive, for which cm_ref_layer_id[i] is equal to rLId, currColourMappingEnableFlag is set equal to 1.
 - Otherwise, currColourMappingEnableFlag is set equal to 0.
- If equalPictureSizeAndOffsetFlag is equal to 1, BitDepthRefLayerY is equal to BitDepthCurrY, BitDepthRefLayerC is equal to BitDepthCurrC, SubWidthRefLayerC is equal to SubWidthCurrC, SubHeightRefLayerC is equal to SubHeightCurrC and currColourMappingEnableFlag is equal to 0, ilRefPic is set equal to rLPic.
- Otherwise, the following applies:
 - The inter-layer reference picture ilRefPic is generated as follows:
 - The PicOrderCntVal value of ilRefPic is set equal to the PicOrderCntVal value of rLPic.
 - The nuh_layer_id value of ilRefPic is set equal to rLId.
 - The variable currLayerId is set equal to the value of nuh_layer_id of the current picture.
 - When VpsInterLayerSamplePredictionEnabled[LayerIdxInVps[currLayerId]][LayerIdxInVps[rLId]] is equal to 1, the following applies:
 - If currColourMappingEnableFlag is equal to 1, the following applies:
 - The colour mapping process as specified in clause H.8.1.4.4 is invoked with the picture sample arrays, rLPicSample_L, rLPicSample_{Cb} and rLPicSample_{Cr}, of the direct reference layer picture rLPic as inputs, and with the colour mapped picture sample arrays, cmPicSample_L, cmPicSample_{Cb} and cmPicSample_{Cr} of the colour mapped reference layer picture cmPic as outputs.
 - BitDepthRefLayerY and BitDepthRefLayerC are set equal to BitDepthCmOutputY and BitDepthCmOutputC, respectively.
 - If equalPictureSizeAndOffsetFlag is equal to 1, BitDepthRefLayerY is equal to BitDepthCurrY, BitDepthRefLayerC is equal to BitDepthCurrC, SubWidthRefLayerC is equal to SubWidthCurrC and SubHeightRefLayerC is equal to SubHeightCurrC, the picture sample arrays rsPicSample_L, rsPicSample_{Cb} and rsPicSample_{Cr} of the inter-layer reference picture ilRefPic are set equal to cmPicSample_L, cmPicSample_{Cb} and cmPicSample_{Cr}, respectively.
 - Otherwise, the picture sample resampling process as specified in clause H.8.1.4.2 is invoked with the picture sample arrays, cmPicSample_L, cmPicSample_{Cb} and cmPicSample_{Cr}, of the colour mapped reference layer picture cmPic as inputs, and with the resampled picture sample arrays, rsPicSample_L, rsPicSample_{Cb} and rsPicSample_{Cr} of the inter-layer reference picture ilRefPic as outputs.
 - Otherwise, the picture sample resampling process as specified in clause H.8.1.4.2 is invoked with the picture sample arrays, rLPicSample_L, rLPicSample_{Cb} and rLPicSample_{Cr}, of the direct reference layer picture rLPic as inputs, and with the resampled picture sample arrays, rsPicSample_L, rsPicSample_{Cb} and rsPicSample_{Cr} of the inter-layer reference picture ilRefPic as outputs.
 - sampleProcessingFlag is set equal to 1.
 - When VpsInterLayerMotionPredictionEnabled[LayerIdxInVps[currLayerId]][LayerIdxInVps[rLId]] is equal to 1, the following applies:
 - A single slice ilRefSlice of the inter-layer reference picture ilRefPic is generated as follows:

- The values of slice_type, num_ref_idx_l0_active_minus1 and num_ref_idx_l1_active_minus1 for the generated slice ilRefSlice are set equal to the values of slice_type, num_ref_idx_l0_active_minus1 and num_ref_idx_l1_active_minus1, respectively, of the first slice of rIPic.
- When ilRefSlice is a P or B slice, for i in the range of 0 to num_ref_idx_l0_active_minus1 of ilRefSlice, inclusive, the reference picture associated with index i in reference picture list 0 of ilRefSlice is set equal to the reference picture associated with index i in reference picture list 0 of the first slice of rIPic.
- When ilRefSlice is a B slice, for i in the range of 0 to num_ref_idx_l1_active_minus1 of ilRefSlice, inclusive, the reference picture associated with index i in reference picture list 1 of ilRefSlice is set equal to the reference picture associated with index i in reference picture list 1 of the first slice of rIPic.
 NOTE – When the inter-layer reference picture ilRefPic is used as the collocated picture for temporal motion vector prediction, all slices of rIPic are constrained to have the same values of slice_type, num_ref_idx_l0_active_minus1 and num_ref_idx_l1_active_minus1.
- If equalPictureSizeAndOffsetFlag is equal to 1, the following applies:
 - The motion and mode parameters of the inter-layer reference picture ilRefPic, including an array CuPredMode specifying the prediction modes, two arrays RefIdxL0 and RefIdxL1 specifying the reference indices, two arrays MvL0 and MvL1 specifying the luma motion vectors, and two arrays PredFlagL0 and PredFlagL1 specifying the prediction list utilization flags, are set equal to those of the decoded direct reference layer picture rIPic, respectively.
- Otherwise, the following applies:
 - The picture motion and mode parameters resampling process as specified in clause H.8.1.4.3 is invoked with the direct reference layer picture rIPic, an array rIPredMode specifying the prediction modes CuPredMode of rIPic, two arrays rIPrefIdxL0 and rIPrefIdxL1 specifying the reference indices of rIPic, two arrays rIMvL0 and rIMvL1 specifying the luma motion vectors of rIPic, and two arrays rIPredFlagL0 and rIPredFlagL1 specifying the prediction list utilization flags of rIPic as inputs, and an array rsPredMode specifying the prediction modes CuPredMode of ilRefPic, two arrays rsRefIdxL0 and rsRefIdxL1 specifying the reference indices of ilRefPic, two arrays rsMvL0 and rsMvL1 specifying the luma motion vectors of ilRefPic, and two arrays rsPredFlagL0 and rsPredFlagL1 specifying the prediction list utilization flags of ilRefPic as outputs.
 - motionProcessingFlag is set equal to 1.
- The following applies:

$$\text{NumRefLayerPicsSampleProcessing} += \text{sampleProcessingFlag} \quad (\text{H-26})$$

$$\text{NumRefLayerPicsMotionProcessing} += \text{motionProcessingFlag} \quad (\text{H-27})$$

$$\text{NumRefLayerPicsProcessing} += \text{sampleProcessingFlag} \mid \mid \text{motionProcessingFlag} \quad (\text{H-28})$$

H.8.1.4.2 Resampling process of picture sample values

H.8.1.4.2.1 General

Inputs to this process are:

- a (PicWidthInSamplesRefLayerY)x(PicHeightInSamplesRefLayerY) array rIPicSample_L of luma samples,
- a (PicWidthInSamplesRefLayerC)x(PicHeightInSamplesRefLayerC) array rIPicSample_{Cb} of chroma samples of the component Cb,
- a (PicWidthInSamplesRefLayerC)x(PicHeightInSamplesRefLayerC) array rIPicSample_{Cr} of chroma samples of the component Cr.

Outputs of this process are:

- a (PicWidthInSamplesCurrY)x(PicHeightInSamplesCurrY) array rsPicSample_L of luma samples,
- a (PicWidthInSamplesCurrC)x(PicHeightInSamplesCurrC) array rsPicSample_{Cb} of chroma samples of the component Cb,

- a $(\text{PicWidthInSamplesCurrC}) \times (\text{PicHeightInSamplesCurrC})$ array rsPicSample_{Cr} of chroma samples of the component Cr .

The resampled luma sample value $\text{rsPicSample}_L[xP][yP]$, with $xP = 0..\text{PicWidthInSamplesCurrY} - 1$, $yP = 0..\text{PicHeightInSamplesCurrY} - 1$, is derived by invoking the luma sample resampling process specified in clause H.8.1.4.2.2 with luma sample location (xP, yP) and the reference luma sample array rPicSample_L given as inputs.

The resampled chroma sample value $\text{rsPicSample}_{Cb}[xP_C][yP_C]$, with $xP_C = 0..\text{PicWidthInSamplesCurrC} - 1$, $yP_C = 0..\text{PicHeightInSamplesCurrC} - 1$, of the chroma component Cb is derived by invoking the chroma sample resampling process specified in clause H.8.1.4.2.3 with chroma sample location (xP_C, yP_C) and the reference chroma sample array rPicSample_{Cb} given as inputs.

The resampled chroma sample value $\text{rsPicSample}_{Cr}[xP_C][yP_C]$, with $xP_C = 0..\text{PicWidthInSamplesCurrC} - 1$, $yP_C = 0..\text{PicHeightInSamplesCurrC} - 1$, of the chroma component Cr is derived by invoking the chroma sample resampling process specified in clause H.8.1.4.2.3 with chroma sample location (xP_C, yP_C) and the reference sample array rPicSample_{Cr} given as inputs.

H.8.1.4.2.2 Resampling process of luma sample values

Inputs to this process are

- a luma sample location (xP, yP) relative to the top-left luma sample of the current picture,
- the luma reference sample array rPicSample_L .

Output of this process is the resampled luma sample value rsLumaSample .

Table H.1 specifies the 8-tap filter coefficients $f_L[p, x]$ with $p = 0..15$ and $x = 0..7$ used for the luma resampling process.

Table H.1 – 16-phase luma resampling filter

Phase p	Interpolation filter coefficients							
	$f_L[p, 0]$	$f_L[p, 1]$	$f_L[p, 2]$	$f_L[p, 3]$	$f_L[p, 4]$	$f_L[p, 5]$	$f_L[p, 6]$	$f_L[p, 7]$
0	0	0	0	64	0	0	0	0
1	0	1	−3	63	4	−2	1	0
2	−1	2	−5	62	8	−3	1	0
3	−1	3	−8	60	13	−4	1	0
4	−1	4	−10	58	17	−5	1	0
5	−1	4	−11	52	26	−8	3	−1
6	−1	3	−9	47	31	−10	4	−1
7	−1	4	−11	45	34	−10	4	−1
8	−1	4	−11	40	40	−11	4	−1
9	−1	4	−10	34	45	−11	4	−1
10	−1	4	−10	31	47	−9	3	−1
11	−1	3	−8	26	52	−11	4	−1
12	0	1	−5	17	58	−10	4	−1
13	0	1	−4	13	60	−8	3	−1
14	0	1	−3	8	62	−5	2	−1
15	0	1	−2	4	63	−3	1	0

The value of the resampled luma sample rsLumaSample is derived by applying the following ordered steps:

1. The derivation process for reference layer sample location used in resampling as specified in clause H.8.1.4.2.4 is invoked with chromaFlag equal to 0 and luma sample location (xP, yP) given as the inputs and luma sample location $(x\text{Ref}16, y\text{Ref}16)$ in units of 1/16-th luma sample as output.
2. The variables $x\text{Ref}$ and $x\text{Phase}$ are derived as follows:

$$x\text{Ref} = (x\text{Ref}16 \gg 4) \quad (\text{H-29})$$

$$x\text{Phase} = (x\text{Ref}16) \% 16 \quad (\text{H-30})$$

3. The variables $y\text{Ref}$ and $y\text{Phase}$ are derived as follows:

$$yRef = (yRef16 \gg 4) \quad (H-31)$$

$$yPhase = (yRef16) \% 16 \quad (H-32)$$

4. The variables shift1, shift2 and offset are derived as follows:

$$shift1 = BitDepthRefLayerY - 8 \quad (H-33)$$

$$shift2 = 20 - BitDepthCurrY \quad (H-34)$$

$$offset = 1 \ll (shift2 - 1) \quad (H-35)$$

5. The sample value tempArray[n] with $n = 0..7$, is derived as follows:

$$yPosRL = Clip3(0, PicHeightInSamplesRefLayerY - 1, yRef + n - 3) \quad (H-36)$$

$$refW = PicWidthInSamplesRefLayerY \quad (H-37)$$

$$\begin{aligned} tempArray[n] = & (f_L[xPhase, 0] * rPicSample_L[Clip3(0, refW - 1, xRef - 3), yPosRL] + \\ & f_L[xPhase, 1] * rPicSample_L[Clip3(0, refW - 1, xRef - 2), yPosRL] + \\ & f_L[xPhase, 2] * rPicSample_L[Clip3(0, refW - 1, xRef - 1), yPosRL] + \\ & f_L[xPhase, 3] * rPicSample_L[Clip3(0, refW - 1, xRef), yPosRL] + \\ & f_L[xPhase, 4] * rPicSample_L[Clip3(0, refW - 1, xRef + 1), yPosRL] + \\ & f_L[xPhase, 5] * rPicSample_L[Clip3(0, refW - 1, xRef + 2), yPosRL] + \\ & f_L[xPhase, 6] * rPicSample_L[Clip3(0, refW - 1, xRef + 3), yPosRL] + \end{aligned} \quad (H-38)$$

$$f_L[xPhase, 7] * rPicSample_L[Clip3(0, refW - 1, xRef + 4), yPosRL]) \gg shift1$$

6. The resampled luma sample value rsLumaSample is derived as follows:

$$\begin{aligned} rsLumaSample = & (f_L[yPhase, 0] * tempArray[0] + \\ & f_L[yPhase, 1] * tempArray[1] + \\ & f_L[yPhase, 2] * tempArray[2] + \\ & f_L[yPhase, 3] * tempArray[3] + \\ & f_L[yPhase, 4] * tempArray[4] + \\ & f_L[yPhase, 5] * tempArray[5] + \\ & f_L[yPhase, 6] * tempArray[6] + \\ & f_L[yPhase, 7] * tempArray[7] + offset) \gg shift2 \end{aligned} \quad (H-39)$$

$$rsLumaSample = Clip3(0, (1 \ll BitDepthCurrY) - 1, rsLumaSample) \quad (H-40)$$

H.8.1.4.2.3 Resampling process of chroma sample values

Inputs to this process are:

- a chroma sample location (xP_C, yP_C) relative to the top-left chroma sample of the current picture,
- the chroma reference sample array rPicSample_C.

Output of this process is the resampled chroma sample value rsChromaSample.

Table H.2 specifies the 4-tap filter coefficients $fc[p, x]$ with $p = 0..15$ and $x = 0..3$ used for the chroma resampling process.

Table H.2 – 16-phase chroma resampling filter

Phase p	Interpolation filter coefficients			
	$fc[p, 0]$	$fc[p, 1]$	$fc[p, 2]$	$fc[p, 3]$
0	0	64	0	0
1	−2	62	4	0
2	−2	58	10	−2
3	−4	56	14	−2
4	−4	54	16	−2
5	−6	52	20	−2
6	−6	46	28	−4
7	−4	42	30	−4

8	-4	36	36	-4
9	-4	30	42	-4
10	-4	28	46	-6
11	-2	20	52	-6
12	-2	16	54	-4
13	-2	14	56	-4
14	-2	10	58	-2
15	0	4	62	-2

The value of the resampled chroma sample value rsChromaSample is derived by applying the following ordered steps:

1. The derivation process for reference layer sample location in resampling as specified in clause H.8.1.4.2.4 is invoked with chromaFlag equal to 1 and chroma sample location (xP_C, yP_C) given as the inputs and chroma sample location (xRef16, yRef16) in units of 1/16-th chroma sample as output.

2. The variables xRef and xPhase are derived as follows:

$$xRef = (xRef16 \gg 4) \quad (H-41)$$

$$xPhase = (xRef16) \% 16 \quad (H-42)$$

3. The variables yRef and yPhase are derived as follows:

$$yRef = (yRef16 \gg 4) \quad (H-43)$$

$$yPhase = (yRef16) \% 16 \quad (H-44)$$

4. The variables shift1, shift2 and offset are derived as follows:

$$shift1 = BitDepthRefLayerC - 8 \quad (H-45)$$

$$shift2 = 20 - BitDepthCurrC \quad (H-46)$$

$$offset = 1 \ll (shift2 - 1) \quad (H-47)$$

5. The sample value tempArray[n] with n = 0..3, is derived as follows:

$$yPosRL = Clip3(0, PicHeightInSamplesRefLayerC - 1, yRef + n - 1) \quad (H-48)$$

$$refWC = PicWidthInSamplesRefLayerC \quad (H-49)$$

$$tempArray[n] = (f_c[xPhase, 0] * rPicSamplec[Clip3(0, refWC - 1, xRef - 1), yPosRL] + f_c[xPhase, 1] * rPicSamplec[Clip3(0, refWC - 1, xRef), yPosRL] + f_c[xPhase, 2] * rPicSamplec[Clip3(0, refWC - 1, xRef + 1), yPosRL] + \quad (H-50)$$

$$f_c[xPhase, 3] * rPicSamplec[Clip3(0, refWC - 1, xRef + 2), yPosRL]) \gg shift1$$

6. The resampled chroma sample value rsChromaSample is derived as follows:

$$rsChromaSample = (f_c[yPhase, 0] * tempArray[0] + f_c[yPhase, 1] * tempArray[1] + f_c[yPhase, 2] * tempArray[2] + f_c[yPhase, 3] * tempArray[3] + offset) \gg shift2 \quad (H-51)$$

$$rsChromaSample = Clip3(0, (1 \ll BitDepthCurrC) - 1, rsChromaSample) \quad (H-52)$$

H.8.1.4.2.4 Derivation process for reference layer sample location in units of 1/16-th sample

Inputs to this process are:

- a variable chromaFlag specifying whether the sample location being derived is that of the luma component or that of one of the chroma colour components.
- a sample location (xP, yP) relative to the top-left sample of the luma component or the top-left sample of one of the chroma components of the current picture depending on the value of chromaFlag.

Output of this process is a sample location (xRef16, yRef16) specifying the reference layer sample location in units of 1/16-th sample relative to the top-left sample of the luma component or the top-left sample of one of the chroma components of the direct reference layer picture depending on the value of chromaFlag.

The variables currOffsetLeft, currOffsetTop, refOffsetLeft and refOffsetTop are derived as follows:

$$\text{currOffsetLeft} = \text{ScaledRefLayerLeftOffset} / (\text{chromaFlag} ? \text{SubWidthCurrC} : 1) \quad (\text{H-53})$$

$$\text{currOffsetTop} = \text{ScaledRefLayerTopOffset} / (\text{chromaFlag} ? \text{SubHeightCurrC} : 1) \quad (\text{H-54})$$

$$\text{refOffsetLeft} = (\text{RefLayerRegionLeftOffset} / (\text{chromaFlag} ? \text{SubWidthRefLayerC} : 1)) \ll 4 \quad (\text{H-55})$$

$$\text{refOffsetTop} = (\text{RefLayerRegionTopOffset} / (\text{chromaFlag} ? \text{SubHeightRefLayerC} : 1)) \ll 4 \quad (\text{H-56})$$

The variables phaseHor, phaseVer, scaleHor and scaleVer are derived as follows:

$$\text{phaseHor} = \text{chromaFlag} ? \text{PhaseHorC} : \text{PhaseHorY} \quad (\text{H-57})$$

$$\text{phaseVer} = \text{chromaFlag} ? \text{PhaseVerC} : \text{PhaseVerY} \quad (\text{H-58})$$

$$\text{scaleHor} = \text{chromaFlag} ? \text{SpatialScaleFactorHorC} : \text{SpatialScaleFactorHorY} \quad (\text{H-59})$$

$$\text{scaleVer} = \text{chromaFlag} ? \text{SpatialScaleFactorVerC} : \text{SpatialScaleFactorVerY} \quad (\text{H-60})$$

The variables addHor and addVer are derived as follows:

$$\text{addHor} = - ((\text{scaleHor} * \text{phaseHor} + 8) \gg 4) \quad (\text{H-61})$$

$$\text{addVer} = - ((\text{scaleVer} * \text{phaseVer} + 8) \gg 4) \quad (\text{H-62})$$

The variables xRef16 and yRef16 are derived as follows:

$$\text{xRef16} = (((\text{xP} - \text{currOffsetLeft}) * \text{scaleHor} + \text{addHor} + (1 \ll 11)) \gg 12) + \text{refOffsetLeft} \quad (\text{H-63})$$

$$\text{yRef16} = (((\text{yP} - \text{currOffsetTop}) * \text{scaleVer} + \text{addVer} + (1 \ll 11)) \gg 12) + \text{refOffsetTop} \quad (\text{H-64})$$

H.8.1.4.3 Resampling process of picture motion and mode parameters

Inputs to this process are:

- a decoded direct reference layer picture rIPic,
- a (PicWidthInSamplesRefLayerY)x(PicHeightInSamplesRefLayerY) array rIPredMode specifying the prediction modes of the direct reference layer picture,
- two (PicWidthInSamplesRefLayerY)x(PicHeightInSamplesRefLayerY) arrays rIRefIdxL0 and rIRefIdxL1 specifying the reference indices of the direct reference layer picture,
- two (PicWidthInSamplesRefLayerY)x(PicHeightInSamplesRefLayerY) arrays rIMvL0 and rIMvL1 specifying the luma motion vectors of the direct reference layer picture,
- two (PicWidthInSamplesRefLayerY)x(PicHeightInSamplesRefLayerY) arrays rIPredFlagL0 and rIPredFlagL1 specifying the prediction list utilization flags of the direct reference layer picture.

Outputs of this process are:

- a (PicWidthInSamplesCurrY)x(PicHeightInSamplesCurrY) array rsPredMode specifying the prediction modes of the resampled picture,

- two (PicWidthInSamplesCurrY)x(PicHeightInSamplesCurrY) arrays rsRefIdxL0 and rsRefIdxL1 specifying the reference indices of the resampled picture,
- two (PicWidthInSamplesCurrY)x(PicHeightInSamplesCurrY) arrays rsMvL0 and rsMvL1 specifying the luma motion vectors of the resampled picture,
- two (PicWidthInSamplesCurrY)x(PicHeightInSamplesCurrY) arrays rsPredFlagL0 and rsPredFlagL1 specifying the prediction list utilization flags of the resampled picture.

For each 16x16 prediction block of the resampled picture with the top-left luma sample location at (xP, yP), where $xP = xB \ll 4$ and $yP = yB \ll 4$, for $xB = 0..((PicWidthInSamplesCurrY + 15) \gg 4) - 1$ and $yB = 0..((PicHeightInSamplesCurrY + 15) \gg 4) - 1$, its motion and mode parameters rsPredMode[xP][yP], rsMvLX[xP][yP], rsRefIdxLX[xP][yP] and rsPredFlagLX[xP][yP], with X being equal to 0 and 1, are derived by applying the following ordered steps:

1. The centre location (xPCtr, yPCtr) of the luma prediction block is derived as follows:

$$xPCtr = xP + 8 \quad (H-65)$$

$$yPCtr = yP + 8 \quad (H-66)$$

2. The variables xRef and yRef are derived as follows:

$$\begin{aligned} xRef = & \\ & (((xPCtr - ScaledRefLayerLeftOffset) * SpatialScaleFactorHorY + (1 \ll 15)) \gg 16) \\ & + RefLayerRegionLeftOffset \end{aligned} \quad (H-67)$$

$$\begin{aligned} yRef = & \\ & (((yPCtr - ScaledRefLayerTopOffset) * SpatialScaleFactorVerY + (1 \ll 15)) \gg 16) \\ & + RefLayerRegionTopOffset \end{aligned} \quad (H-68)$$

3. The rounded reference layer luma sample location (xRL, yRL) is derived as follows:

$$xRL = ((xRef + 4) \gg 4) \ll 4 \quad (H-69)$$

$$yRL = ((yRef + 4) \gg 4) \ll 4 \quad (H-70)$$

4. The variable rsPredMode[xP][yP] is derived as follows:

$$\begin{aligned} & \text{if}(xRL < 0 \mid \mid xRL \geq PicWidthInSamplesRefLayerY \mid \mid yRL < 0 \mid \mid \\ & \quad yRL \geq PicHeightInSamplesRefLayerY), \quad (H-71) \\ & \quad rsPredMode[xP][yP] = MODE_INTRA \\ & \text{else} \\ & \quad rsPredMode[xP][yP] = rlPredMode[xRL][yRL] \end{aligned}$$

5. For X being each of 0 and 1, the variables rsMvLX[xP][yP], rsRefIdxLX[xP][yP] and rsPredFlagLX[xP][yP] are derived as follows:

- If rsPredMode[xP][yP] is equal to MODE_INTER, the following applies:

- rsRefIdxLX[xP][yP] and rsPredFlagLX[xP][yP] are derived as follows:

$$rsRefIdxLX[xP][yP] = rlRefIdxLX[xRL][yRL] \quad (H-72)$$

$$rsPredFlagLX[xP][yP] = rlPredFlagLX[xRL][yRL] \quad (H-73)$$

- rsMvLX[xP][yP][0] is derived as follows:

- If ScaledRefRegionWidthInSamplesY is not equal to RefLayerRegionWidthInSamplesY, the following applies:

$$\text{scaleMVX} = \text{Clip3}(-4096, 4095, ((\text{ScaledRefRegionWidthInSamplesY} \ll 8)(\text{H-74}) + (\text{RefLayerRegionWidthInSamplesY} \gg 1)) / \text{RefLayerRegionWidthInSamplesY})$$

$$\begin{aligned} \text{rsMvLX}[xP][yP][0] &= \text{Clip3}(-32768, 32767, \text{Sign}(\text{scaleMVX} * \\ &\quad \text{rlMvLX}[xRL][yRL][0]) * ((\text{Abs}(\text{scaleMVX} * \text{rlMvLX}[xRL][yRL][0]) \\ &\quad (\text{H-75}) \\ &\quad + 127) \gg 8)) \end{aligned}$$

- Otherwise, the following applies:

$$\text{rsMvLX}[xP][yP][0] = \text{rlMvLX}[xRL][yRL][0] \quad (\text{H-76})$$

- rsMvLX[xP][yP][1] is derived as follows:

- If ScaledRefRegionHeightInSamplesY is not equal to RefLayerRegionHeightInSamplesY, the following applies:

$$\begin{aligned} \text{scaleMVY} &= \text{Clip3}(-4096, 4095, ((\text{ScaledRefRegionHeightInSamplesY} \ll 8)(\text{H-77}) \\ &\quad + (\text{RefLayerRegionHeightInSamplesY} \gg 1)) / \\ &\quad \text{RefLayerRegionHeightInSamplesY}) \end{aligned}$$

$$\begin{aligned} \text{rsMvLX}[xP][yP][1] &= \text{Clip3}(-32768, 32767, \text{Sign}(\text{scaleMVY} * \\ &\quad \text{rlMvLX}[xRL][yRL][1]) * ((\text{Abs}(\text{scaleMVY} * \text{rlMvLX}[xRL][yRL][1]) \\ &\quad (\text{H-78}) \\ &\quad + 127) \gg 8)) \end{aligned}$$

- Otherwise, the following applies:

$$\text{rsMvLX}[xP][yP][1] = \text{rlMvLX}[xRL][yRL][1] \quad (\text{H-79})$$

- Otherwise (rsPredMode[xP][yP] is equal to MODE_INTRA), the following applies:
 - rsMvL0[xP][yP][0], rsMvL0[xP][yP][1], rsMvL1[xP][yP][0] and rsMvL1[xP][yP][1] are set equal to 0.
 - rsRefIdxL0[xP][yP] and rsRefIdxL1[xP][yP] are set equal to -1.
 - rsPredFlagL0[xP][yP] and rsPredFlagL1[xP][yP] are set equal to 0.

H.8.1.4.4 Colour mapping process of picture sample values

H.8.1.4.4.1 General

Inputs to this process are:

- a (PicWidthInSamplesRefLayerY)x(PicHeightInSamplesRefLayerY) array rlPicSample_L of luma samples,
- a (PicWidthInSamplesRefLayerC)x(PicHeightInSamplesRefLayerC) array rlPicSample_{Cb} of chroma samples of the component Cb,
- a (PicWidthInSamplesRefLayerC)x(PicHeightInSamplesRefLayerC) array rlPicSample_{Cr} of chroma samples of the component Cr.

Outputs of this process are:

- a (PicWidthInSamplesRefLayerY)x(PicHeightInSamplesRefLayerY) array cmPicSample_L of luma samples,
- a (PicWidthInSamplesRefLayerC)x(PicHeightInSamplesRefLayerC) array cmPicSample_{Cb} of chroma samples of the component Cb,
- a (PicWidthInSamplesRefLayerC)x(PicHeightInSamplesRefLayerC) array cmPicSample_{Cr} of chroma samples of the component Cr.

The colour mapped luma sample cmPicSample_L[xP][yP] with xP = 0..PicWidthInSamplesRefLayerY - 1, yP = 0..PicHeightInSamplesRefLayerY - 1 is derived by invoking the colour mapping process of luma sample values as

specified in clause H.8.1.4.4.2 with luma sample location (x_P, y_P), sample arrays $rlPicSampleL$, $rlPicSampleCb$ and $rlPicSampleCr$ given as inputs.

The colour mapped chroma sample $cmPicSampleCb[x_C][y_C]$ with $x_C = 0..PicWidthInSamplesRefLayerC - 1$, $y_C = 0..PicHeightInSamplesRefLayerC - 1$ is derived by invoking the colour mapping process of chroma sample values as specified in clause H.8.1.4.4.3 with chroma sample location (x_C, y_C), sample arrays $rlPicSampleL$, $rlPicSampleCb$ $rlPicSampleCr$ and $cIdx$ equal to 0 given as inputs.

The colour mapped chroma sample $cmPicSampleCr[x_C][y_C]$ with $x_C = 0..PicWidthInSamplesRefLayerC - 1$, $y_C = 0..PicHeightInSamplesRefLayerC - 1$ is derived by invoking the colour mapping process of chroma sample values as specified in clause H.8.1.4.4.3 with chroma sample location (x_C, y_C), sample arrays $rlPicSampleL$, $rlPicSampleCb$, $rlPicSampleCr$ and $cIdx$ equal to 1 given as inputs.

H.8.1.4.4.2 Colour mapping process of luma sample values

Inputs to this process are:

- a luma sample location (x_P, y_P) specifying the luma sample location relative to the top-left luma sample of the direct reference layer picture,
- the luma reference layer sample array $rlPicSample_Y$
- the chroma reference layer sample array $rlPicSample_{Cb}$ of the Cb component
- the chroma reference layer sample array $rlPicSample_{Cr}$ of the Cr component

Output of the process is a colour mapped luma sample value $cmLumaSample$

The chroma sample location (x_{P_C}, y_{P_C}) is set equal to ($x_P / SubWidthRefLayerC, y_P / SubHeightRefLayerC$).

The value of $cmLumaSample$ is derived by applying the following ordered steps:

1. The variables $yShift2Idx$, $cShift2Idx$ are derived as follows:

$$yShift2Idx = BitDepthCmInputY - cm_octant_depth - cm_y_part_num_log2 \quad (H-80)$$

$$cShift2Idx = BitDepthCmInputC - cm_octant_depth \quad (H-81)$$

2. The variables $nMappingShift$ and $nMappingOffset$ are derived as follows:

$$nMappingShift = 10 + BitDepthCmInputY - BitDepthCmOutputY \quad (H-82)$$

$$nMappingOffset = 1 \ll (nMappingShift - 1) \quad (H-83)$$

3. The variables $tempCb$ and $tempCr$ are derived as follows:

- If $SubWidthRefLayerC$ is equal to 2 and $SubHeightRefLayerC$ is equal to 2, the following applies:

- If $x_P \% 2$ is equal to 0 and $y_P \% 2$ is equal to 0, the following applies:

$$yP2_C = \text{Max}(0, y_{P_C} - 1) \quad (H-84)$$

$$tempCb = (rlPicSample_{Cb}[x_{P_C}][y_{P_C}] * 3 + rlPicSample_{Cb}[x_{P_C}][yP2_C] + 2) \gg 2 \quad (H-85)$$

$$tempCr = (rlPicSample_{Cr}[x_{P_C}][y_{P_C}] * 3 + rlPicSample_{Cr}[x_{P_C}][yP2_C] + 2) \gg 2 \quad (H-86)$$

- Otherwise, if $x_P \% 2$ is equal to 0 and $y_P \% 2$ is equal to 1, the following applies:

$$yP2_C = \text{Min}(y_{P_C} + 1, PicHeightInSamplesRefLayerC - 1) \quad (H-87)$$

$$tempCb = (rlPicSample_{Cb}[x_{P_C}][y_{P_C}] * 3 + rlPicSample_{Cb}[x_{P_C}][yP2_C] + 2) \gg 2 \quad (H-88)$$

$$tempCr = (rlPicSample_{Cr}[x_{P_C}][y_{P_C}] * 3 + rlPicSample_{Cr}[x_{P_C}][yP2_C] + 2) \gg 2 \quad (H-89)$$

- Otherwise, if $xP \% 2$ is equal to 1 and $yP \% 2$ is equal to 0, the following applies:

$$xP2_C = \text{Min}(xP_C + 1, \text{PicWidthInSamplesRefLayerC} - 1) \quad (\text{H-90})$$

$$yP2_C = \text{Max}(0, yP_C - 1) \quad (\text{H-91})$$

$$\text{tempCb} = (\text{rPicSampleCb}[xP_C][yP2_C] + \text{rPicSampleCb}[xP2_C][yP2_C] + (\text{rPicSampleCb}[xP_C][yP_C] + \text{rPicSampleCb}[xP2_C][yP_C]) * 3 + 4) \gg 3 \quad (\text{H-92})$$

$$\text{tempCr} = (\text{rPicSampleCr}[xP_C][yP2_C] + \text{rPicSampleCr}[xP2_C][yP2_C] + (\text{rPicSampleCr}[xP_C][yP_C] + \text{rPicSampleCr}[xP2_C][yP_C]) * 3 + 4) \gg 3 \quad (\text{H-93})$$
- Otherwise ($xP \% 2$ is equal to 1 and $yP \% 2$ is equal to 1), the following applies:

$$xP2_C = \text{Min}(xP_C + 1, \text{PicWidthInSamplesRefLayerC} - 1) \quad (\text{H-94})$$

$$yP2_C = \text{Min}(yP_C + 1, \text{PicHeightInSamplesRefLayerC} - 1) \quad (\text{H-95})$$

$$\text{tempCb} = ((\text{rPicSampleCb}[xP_C][yP_C] + \text{rPicSampleCb}[xP2_C][yP_C]) * 3 + \text{rPicSampleCb}[xP_C][yP2_C] + \text{rPicSampleCb}[xP2_C][yP2_C] + 4) \gg 3 \quad (\text{H-96})$$

$$\text{tempCr} = ((\text{rPicSampleCr}[xP_C][yP_C] + \text{rPicSampleCr}[xP2_C][yP_C]) * 3 + \text{rPicSampleCr}[xP_C][yP2_C] + \text{rPicSampleCr}[xP2_C][yP2_C] + 4) \gg 3 \quad (\text{H-97})$$
- Otherwise, if SubWidthRefLayerC is equal to 2, the following applies:
 - If $xP \% 2$ is equal to 1, the following applies:

$$xP2_C = \text{Min}(xP_C + 1, \text{PicWidthInSamplesRefLayerC} - 1) \quad (\text{H-98})$$

$$\text{tempCb} = (\text{rPicSampleCb}[xP_C][yP_C] + \text{rPicSampleCb}[xP2_C][yP_C] + 1) \gg 1 \quad (\text{H-99})$$

$$\text{tempCr} = (\text{rPicSampleCr}[xP_C][yP_C] + \text{rPicSampleCr}[xP2_C][yP_C] + 1) \gg 1 \quad (\text{H-100})$$
 - Otherwise ($xP \% 2$ is equal to 0), the following applies:

$$\text{tempCb} = \text{rPicSampleCb}[xP_C][yP_C] \quad (\text{H-101})$$

$$\text{tempCr} = \text{rPicSampleCr}[xP_C][yP_C] \quad (\text{H-102})$$
- Otherwise (SubWidthRefLayerC is equal to 1 and $\text{SubHeightRefLayerC}$ is equal to 1), the following applies:

$$\text{tempCb} = \text{rPicSampleCb}[xP_C][yP_C] \quad (\text{H-103})$$

$$\text{tempCr} = \text{rPicSampleCr}[xP_C][yP_C] \quad (\text{H-104})$$

4. The value of cmLumaSample is derived as follows:

$$\text{idxY} = \text{rPicSampleY}[xP][yP] \gg y\text{Shift2Idx} \quad (\text{H-105})$$

$$\text{idxCb} = (\text{cm_octant_depth} == 1) ? (\text{tempCb} \geq \text{CMThreshU}) : (\text{tempCb} \gg c\text{Shift2Idx}) \quad (\text{H-106})$$

$$\text{idxCr} = (\text{cm_octant_depth} == 1) ? (\text{tempCr} \geq \text{CMThreshV}) : (\text{tempCr} \gg c\text{Shift2Idx}) \quad (\text{H-107})$$

$$\begin{aligned} \text{cmLumaSample} = & ((\text{LutY}[\text{idxY}][\text{idxCb}][\text{idxCr}][0] * \text{rPicSample}_Y[\text{xP}][\text{yP}] \\ & + \text{LutY}[\text{idxY}][\text{idxCb}][\text{idxCr}][1] * \text{tempCb} + \text{LutY}[\text{idxY}][\text{idxCb}][\text{idxCr}][2] * \text{tempCr} \\ & + \text{nMappingOffset}) >> \text{nMappingShift}) + \text{LutY}[\text{idxY}][\text{idxCb}][\text{idxCr}][3] \end{aligned} \quad (\text{H-108})$$

$$\text{cmLumaSample} = \text{Clip3}(0, (1 << \text{BitDepthCmOutputY}) - 1, \text{cmLumaSample}) \quad (\text{H-109})$$

H.8.1.4.4.3 Colour mapping process of chroma sample values

Inputs to this process are:

- a chroma sample location (x_{P_C} , y_{P_C}) specifying the chroma sample location relative to the top-left chroma sample of the direct reference layer picture,
- the luma reference sample array rPicSample_Y ,
- the chroma reference sample array rPicSample_{Cb} of the Cb component,
- the chroma reference sample array rPicSample_{Cr} of the Cr component,
- a variable $cIdx$ specifying the chroma component index.

Output of the process is a colour mapped chroma sample value cmChromaSample .

The luma sample location (x_P , y_P) is set equal to ($x_{P_C} * \text{SubWidthRefLayerC}$, $y_{P_C} * \text{SubHeightRefLayerC}$).

The colour mapping table LutC is set equal to LutCb if $cIdx$ is equal to 0 and set equal to LutCr otherwise.

The value of cmChromaSample is derived by applying the following ordered steps:

1. The variables $yShift2Idx$, $cShift2Idx$ are derived as follows:

$$yShift2Idx = \text{BitDepthCmInputY} - \text{cm_octant_depth} - \text{cm_y_part_num_log2} \quad (\text{H-110})$$

$$cShift2Idx = \text{BitDepthCmInputC} - \text{cm_octant_depth} \quad (\text{H-111})$$

2. The variables nMappingShift and nMappingOffset are derived as follows:

$$\text{nMappingShift} = 10 + \text{BitDepthCmInputY} - \text{BitDepthCmOutputY} \quad (\text{H-112})$$

$$\text{nMappingOffset} = 1 << (\text{nMappingShift} - 1) \quad (\text{H-113})$$

3. The variable tempY is derived as follows:

- If SubWidthRefLayerC is equal to 2 and $\text{SubHeightRefLayerC}$ is equal to 2, the following applies:

$$\text{tempY} = (\text{rPicSample}_Y[\text{xP}][\text{yP}] + \text{rPicSample}_Y[\text{xP}][\text{yP} + 1] + 1) >> 1 \quad (\text{H-114})$$

- Otherwise (SubWidthRefLayerC is not equal to 2 or $\text{SubHeightRefLayerC}$ is not equal to 2), the following applies:

$$\text{tempY} = \text{rPicSample}_Y[\text{xP}][\text{yP}] \quad (\text{H-115})$$

4. The value of cmChromaSample is derived as follows:

$$\text{idxY} = \text{tempY} >> yShift2Idx \quad (\text{H-116})$$

$$\begin{aligned} \text{idxCb} = & (\text{cm_octant_depth} == 1) ? \\ & (\text{rPicSample}_{Cb}[\text{xP}_C][\text{yP}_C] >= \text{CMThreshU}) : (\text{rPicSample}_{Cb}[\text{xP}_C][\text{yP}_C] >> cShift2Idx) \end{aligned} \quad (\text{H-117})$$

$$\begin{aligned} \text{idxCr} = & (\text{cm_octant_depth} == 1) ? \\ & (\text{rPicSample}_{Cr}[\text{xP}_C][\text{yP}_C] >= \text{CMThreshV}) : (\text{rPicSample}_{Cr}[\text{xP}_C][\text{yP}_C] >> cShift2Idx) \end{aligned} \quad (\text{H-118})$$

$$\begin{aligned} \text{cmChromaSample} = & ((\text{LutC}[\text{idxY}][\text{idxCb}][\text{idxCr}][0] * \text{tempY} \\ & + \text{LutC}[\text{idxY}][\text{idxCb}][\text{idxCr}][1] * \text{rPicSampleCb}[\text{xPc}][\text{yPc}] \\ & + \text{LutC}[\text{idxY}][\text{idxCb}][\text{idxCr}][2] * \text{rPicSampleCr}[\text{xPc}][\text{yPc}] \\ & + \text{nMappingOffset}) >> \text{nMappingShift}) + \text{LutC}[\text{idxY}][\text{idxCb}][\text{idxCr}][3] \end{aligned} \quad (\text{H-119})$$

$$\text{cmChromaSample} = \text{Clip3}(0, (1 \ll \text{BitDepthCmOutputC}) - 1, \text{cmChromaSample}) \quad (\text{H-120})$$

H.8.2 NAL unit decoding process

The specification in clause F.8.2 apply.

H.8.3 Slice decoding processes

H.8.3.1 Decoding process for picture order count

The specifications in clause F.8.3.1 apply.

H.8.3.2 Decoding process for reference picture set

The specifications in clause F.8.3.2 apply.

H.8.3.3 Decoding process for generating unavailable reference pictures

The specifications in clause F.8.3.3 apply.

H.8.3.4 Decoding process for reference picture lists construction

The specifications in clause F.8.3.4 apply with the following additions:

NOTE – Because bitstreams conforming to this annex are constrained to allow only zero-valued motion vectors for inter prediction using inter-layer reference pictures, it is suggested that a scalable encoder should disable temporal motion vector prediction for the current picture (by setting `slice_temporal_mvp_enabled_flag` to zero) when the reference picture lists of all slices in the current picture include only inter-layer reference pictures. This way, the encoder would be able to avoid the need to send the slice segment header syntax elements `collocated_from_l0_flag` and `collocated_ref_idx`.

H.8.4 Decoding process for coding units coded in intra prediction mode

The specifications in clause F.8.4 apply.

H.8.5 Decoding process for coding units coded in inter prediction mode

The specifications in clause F.8.5 apply with the following additions:

It is a requirement of bitstream conformance that, for X being replaced by either 0 or 1, the variables `mvLX[0]` and `mvLX[1]` as an output of clause 8.5.3.1 shall be equal to 0 if the value of `refIdxLX` as an output of clause 8.5.3.1 corresponds to an inter-layer reference picture. That is, in any conforming bitstream, for X being replaced by either 0 or 1, upon invoking the decoding process in clause 8.5.3.1, the values of the syntax elements `merge_idx`, `mvp_lx_flag`, `ref_idx_lx`, `MvdLX` and `mvd_l1_zero_flag` shall always result in zero values for `mvLX[0]` and `mvLX[1]` when the value of `refIdxLX` of the reference picture list `RefPicListX` indicates an inter-layer reference picture.

The variable `currLayerId` is set equal to `nuh_layer_id` of the current picture.

It is a requirement of bitstream conformance that when the reference picture represented by the variable `refIdxLX` and derived by invoking clause 8.5.3.2, for X being replaced by either 0 or 1, is an inter-layer reference picture, `VpsInterLayerSamplePredictionEnabled[LayerIdxInVps[currLayerId]][LayerIdxInVps[rLid]]` shall be equal to 1, where `rLid` is set equal to `nuh_layer_id` of the direct reference layer picture from which the inter-layer reference picture is derived.

It is a requirement of bitstream conformance that when the collocated picture `colPic`, used for temporal motion vector prediction and derived by invoking clause 8.5.3.2.7, is an inter-layer reference picture, `VpsInterLayerMotionPredictionEnabled[LayerIdxInVps[currLayerId]][LayerIdxInVps[rLid]]` shall be equal to 1, where `rLid` is set equal to `nuh_layer_id` of the direct reference layer picture from which the inter-layer reference picture is derived.

It is a requirement of bitstream conformance that the collocated picture `colPic`, used for temporal motion vector prediction and derived by invoking clause 8.5.3.2.7, shall not be an inter-layer reference picture if the direct reference layer picture, from which the inter-layer reference picture is derived, is coded using two or more slice segments and any of the following conditions is true:

- The slice segment header syntax element `slice_type` of at least one of the slice segments of the direct reference layer picture is different from the slice segment header syntax element `slice_type` of another slice segment of the direct reference layer picture;
- For X being replaced by either 0 or 1, the slice segment header syntax element `num_ref_idx_lX_active_minus1` of at least one of the slice segments of the direct reference layer picture is different from the slice segment header syntax element `num_ref_idx_lX_active_minus1` of another slice segment of the direct reference layer picture;
- For X being replaced by either 0 or 1, the reference picture list `RefPicListX` of at least one of the slice segments of the direct reference layer picture is different from the reference picture list `RefPicListX` of another slice segment of the direct reference layer picture.

H.8.6 Scaling, transformation and array construction process prior to deblocking filter process

The specifications in clause F.8.6 apply.

H.8.7 In-loop filter process

The specifications in clause F.8.7 apply.

H.9 Parsing process

The specifications in clause F.9 apply.

H.10 Specification of bitstream subsets

The specifications in clause F.10 and its subclauses apply.

H.11 Profiles, tiers and levels

H.11.1 Profiles

H.11.1.1 Scalable Main and Scalable Main 10 profiles

For a layer in an output operation point associated with an OLS in a bitstream, the layer being conforming to the Scalable Main or Scalable Main 10 profile, the following applies:

- Let `olsIdx` be the OLS index of the OLS, the sub-bitstream `subBitstream` and the base layer sub-bitstream `baseBitstream` are derived as specified in clause F.11.3.

When `vps_base_layer_internal_flag` is equal to 1, the base layer sub-bitstream `baseBitstream` shall obey the following constraints:

- When the layer conforms to the Scalable Main profile, the base layer sub-bitstream `baseBitstream` shall be indicated to conform to the Main profile.
- When the layer conforms to the Scalable Main 10 profile, the base layer sub-bitstream `baseBitstream` shall be indicated to conform to the Main 10 profile or the Main profile.

The sub-bitstream `subBitstream` shall obey the following constraints:

- All active VPSs shall have `vps_num_rep_formats_minus1` in the range of 0 to 15, inclusive.
- All active SPSs for layers in `subBitstream` shall have `chroma_format_idc` equal to 1 only.
- All active SPSs for layers in `subBitstream` shall have `transform_skip_rotation_enabled_flag`, `transform_skip_context_enabled_flag`, `implicit_rdpem_enabled_flag`, `explicit_rdpem_enabled_flag`, `extended_precision_processing_flag`, `intra_smoothing_disabled_flag`, `high_precision_offsets_enabled_flag`, `persistent_rice_adaptation_enabled_flag` and `cabac_bypass_alignment_enabled_flag`, when present, equal to 0 only.
- `CtbLog2SizeY` derived from all active SPSs for layers in `subBitstream` shall be in the range of 4 to 6, inclusive.
- All active PPSs for layers in `subBitstream` shall have `log2_max_transform_skip_block_size_minus2` and `chroma_qp_offset_list_enabled_flag`, when present, equal to 0 only.
- The variables `NumRefLayerPicsProcessing`, `NumRefLayerPicsSampleProcessing` and `NumRefLayerPicsMotionProcessing` shall be less than or equal to 1 for each decoded picture with `nuh_layer_id` included in `layerIdListTarget` that was used to derive `subBitstream`.
- `ScalabilityId[j][smIdx]` derived according to any active VPS shall be equal to 0 for any `smIdx` value not equal to 2 or 3 and for any value of `j` such that `layer_id_in_nuh[j]` is among `layerIdListTarget` that was used to derive `subBitstream`.

- For a layer with `nuh_layer_id` `iNuhLid` equal to any value included in `layerIdListTarget` that was used to derive `subBitstream`, the value of `NumRefLayers[iNuhLid]`, which specifies the total number of direct and indirect reference layers and is derived as specified in F.7.4.3.1, shall be less than or equal to 4.
- All active SPSs for layers in `subBitstream` shall have `sps_range_extension_flag` and `sps_scc_extension_flag` equal to 0 only.
- All active PPSs for layers in `subBitstream` shall have `pps_range_extension_flag` and `pps_scc_extension_flag` equal to 0 only.
- When an active PPS for any layer in `subBitstream` has `tiles_enabled_flag` equal to 1, it shall have `entropy_coding_sync_enabled_flag` equal to 0.
- When an active PPS for any layer in `subBitstream` has `tiles_enabled_flag` equal to 1, `ColumnWidthInLumaSamples[i]` shall be greater than or equal to 256 for all values of `i` in the range of 0 to `num_tile_columns_minus1`, inclusive, and `RowHeightInLumaSamples[j]` shall be greater than or equal to 64 for all values of `j` in the range of 0 to `num_tile_rows_minus1`, inclusive.
- The number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing `coding_tree_unit()` data for any CTU shall be less than or equal to $5 * \text{RawCtuBits} / 3$.
- `general_level_idc` and `sub_layer_level_idc[i]` for all values of `i` in active SPSs for any layer in `subBitstream` shall not be equal to 255 (which indicates level 8.5).
- For any active VPS, `DependencyId[i]` shall be greater than `DependencyId[j]` for any values of `i` and `j` among `layerIdListTarget` that was used to derive `subBitstream` such that `AuxId[i]` is equal to `AuxId[j]` and `i` is greater than `j`.

When the layer conforms to the Scalable Main profile, the sub-bitstream `subBitstream` shall obey the following constraints:

- All active SPSs for layers in `subBitstream` shall have `bit_depth_luma_minus8` equal to 0 only.
- All active SPSs for layers in `subBitstream` shall have `bit_depth_chroma_minus8` equal to 0 only.
- All active PPSs for layers in `subBitstream` shall have `colour_mapping_enabled_flag` equal to 0 only.
- The tier and level constraints specified for the Scalable Main profile in clause H.11.2 shall be fulfilled.

When the layer conforms to the Scalable Main 10 profile, the sub-bitstream `subBitstream` shall obey the following constraints:

- All active SPSs for layers in `subBitstream` shall have `bit_depth_luma_minus8` in the range of 0 to 2, inclusive.
- All active SPSs for layers in `subBitstream` shall have `bit_depth_chroma_minus8` in the range of 0 to 2, inclusive.
- The tier and level constraints specified for the Scalable Main profile in clause H.11.2 shall be fulfilled.

In the remainder of this clause and clause H.11.2.1, all syntax elements in the `profile_tier_level()` syntax structure refer to those in the `profile_tier_level()` syntax structure associated with the layer.

Conformance of a layer in an output operation point associated with an OLS in a bitstream to the Scalable Main profile is indicated as follows:

- If `OpTid` of the output operation point is equal to `vps_max_sub_layer_minus1`, the conformance is indicated by `general_profile_idc` being equal to 7 or `general_profile_compatibility_flag[7]` being equal to 1, and `general_max_12bit_constraint_flag` being equal to 1, `general_max_10bit_constraint_flag` being equal to 1, `general_max_8bit_constraint_flag` being equal to 1, `general_max_422chroma_constraint_flag` being equal to 1, `general_max_420chroma_constraint_flag` being equal to 1, `general_max_monochrome_constraint_flag` being equal to 0, `general_intra_constraint_flag` being equal to 0, `general_one_picture_only_constraint_flag` being equal to 0 and `general_lower_bit_rate_constraint_flag` being equal to 1.
- Otherwise (`OpTid` of the output operation point is less than `vps_max_sub_layer_minus1`), the conformance is indicated by `sub_layer_profile_idc[OpTid]` being equal to 7 or `sub_layer_profile_compatibility_flag[OpTid][7]` being equal to 1, and `sub_layer_max_12bit_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_10bit_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_8bit_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_422chroma_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_420chroma_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_monochrome_constraint_flag[OpTid]` being equal to 0, `sub_layer_intra_constraint_flag[OpTid]` being equal to 0, and `sub_layer_one_picture_only_constraint_flag[OpTid]` being equal to 0 and `sub_layer_lower_bit_rate_constraint_flag[OpTid]` being equal to 1.

Conformance of a layer in an output operation point associated with an OLS in a bitstream to the Scalable Main 10 profile is indicated as follows:

- If OpTid of the output operation point is equal to vps_max_sub_layer_minus1, the conformance is indicated by general_profile_idc being equal to 7 or general_profile_compatibility_flag[7] being equal to 1, and general_max_12bit_constraint_flag being equal to 1, general_max_10bit_constraint_flag being equal to 1, general_max_8bit_constraint_flag being equal to 0, general_max_422chroma_constraint_flag being equal to 1, general_max_420chroma_constraint_flag being equal to 1, general_max_monochrome_constraint_flag being equal to 0, general_intra_constraint_flag being equal to 0, general_one_picture_only_constraint_flag being equal to 0 and general_lower_bit_rate_constraint_flag being equal to 1.
- Otherwise (OpTid of the output operation point is less than vps_max_sub_layer_minus1), the conformance is indicated by sub_layer_profile_idc[OpTid] being equal to 7 or sub_layer_profile_compatibility_flag[OpTid][7] being equal to 1, and sub_layer_max_12bit_constraint_flag[OpTid] being equal to 1, sub_layer_max_10bit_constraint_flag[OpTid] being equal to 1, sub_layer_max_8bit_constraint_flag[OpTid] being equal to 0, sub_layer_max_422chroma_constraint_flag[OpTid] being equal to 1, sub_layer_max_420chroma_constraint_flag[OpTid] being equal to 1, sub_layer_max_monochrome_constraint_flag[OpTid] being equal to 0, sub_layer_intra_constraint_flag[OpTid] being equal to 0, and sub_layer_one_picture_only_constraint_flag[OpTid] being equal to 0 and sub_layer_lower_bit_rate_constraint_flag[OpTid] being equal to 1.

H.11.1.2 Scalable format range extensions profiles

The following profiles, collectively referred to as the scalable format range extensions profiles, are specified in this clause:

- The Scalable Monochrome, Scalable Monochrome 12 and Scalable Monochrome 16 profiles
- The Scalable Main 4:4:4 profile

For a layer in an output operation point associated with an OLS in a bitstream, the layer being conforming to the Scalable Monochrome, Scalable Monochrome 12, Scalable Monochrome 16 or Scalable Main 4:4:4 profile, the following applies:

- Let olsIdx be the OLS index of the OLS, the sub-bitstream subBitstream and the base layer sub-bitstream baseBitstream are derived as specified in clause F.11.3.

When vps_base_layer_internal_flag is equal to 1, the base layer sub-bitstream baseBitstream shall obey the following constraints:

- The base layer sub-bitstream baseBitstream shall be indicated to conform to the Main profile, the Main 10 profile or a format range extensions profile.

The sub-bitstream subBitstream shall obey the following constraints:

- All active VPSs shall have vps_num_rep_formats_minus1 in the range of 0 to 15, inclusive.
- All active SPSs for layers in subBitstream shall have separate_colour_plane_flag, cabac_bypass_alignment_enabled_flag, when present, equal to 0 only.
- CtbLog2SizeY derived from all active SPSs for layers in subBitstream shall be in the range of 4 to 6, inclusive.
- The variables NumRefLayerPicsProcessing, NumRefLayerPicsSampleProcessing, and NumRefLayerPicsMotionProcessing shall be less than or equal to 1 for each decoded picture with nuh_layer_id included in layerIdListTarget that was used to derive subBitstream.
- ScalabilityId[j][smIdx] derived according to any active VPS shall be equal to 0 for any smIdx value not equal to 2 or 3 and for any value of j such that layer_id_in_nuh[j] is among layerIdListTarget that was used to derive subBitstream.
- For a layer with nuh_layer_id iNuhLId equal to any value included in layerIdListTarget that was used to derive subBitstream, the value of NumRefLayers[iNuhLId], which specifies the total number of direct and indirect reference layers and is derived as specified in F.7.4.3.1, shall be less than or equal to 4.
- The constraints specified in Table H.3, in which entries marked with "–" indicate that the table entry does not impose a profile-specific constraint on the corresponding syntax element, shall apply for all active SPSs and PPSs for layers in subBitstream.

NOTE – For some syntax elements with table entries marked with "–", a constraint may be imposed indirectly – e.g., by semantics constraints that are imposed elsewhere in this Specification when other specified constraints are fulfilled.

- All active SPSs for layers in subBitstream shall have the same value of chroma_format_idc.
- All active SPSs for layers in subBitstream shall have sps_scc_extension_flag equal to 0 only.
- All active PPSs for layers in subBitstream shall have pps_scc_extension_flag equal to 0 only.

- When an active PPS for any layer in subBitstream has `tiles_enabled_flag` equal to 1, it shall have `entropy_coding_sync_enabled_flag` equal to 0.
- When an active PPS for any layer in subBitstream has `tiles_enabled_flag` equal to 1, `ColumnWidthInLumaSamples[i]` shall be greater than or equal to 256 for all values of `i` in the range of 0 to `num_tile_columns_minus1`, inclusive, and `RowHeightInLumaSamples[j]` shall be greater than or equal to 64 for all values of `j` in the range of 0 to `num_tile_rows_minus1`, inclusive.
- The number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing `coding_tree_unit()` data for any CTU shall be less than or equal to $5 * \text{RawCtuBits} / 3$.
- For any active VPS, `DependencyId[i]` shall be greater than `DependencyId[j]` for any values of `i` and `j` among `layerIdListTarget` that was used to derive subBitstream such that `AuxId[i]` is equal to `AuxId[j]` and `i` is greater than `j`.
- In bitstreams conforming to the Scalable Monochrome, Scalable Monochrome 12, Scalable Monochrome 16 or Scalable Main 4:4:4 profiles, `general_level_idc` and `sub_layer_level_idc[i]` for all values of `i` in active SPSs for all layers shall not be equal to 255 (which indicates level 8.5).
- The tier and level constraints specified for the Scalable Monochrome, Scalable Monochrome 12, Scalable Monochrome 16, or Scalable Main 4:4:4 profiles in clause H.11.2, as applicable, shall be fulfilled.

Table H.3 – Allowed values for syntax elements in the scalable format range extensions profiles

Profile for which constraint is specified	chroma_format_idc	bit_depth_luma_minus8 and bit_depth_chroma_minus8	transform_skip_rotation_enabled_flag, transform_skip_context_enabled_flag, implicit_rdpem_enabled_flag, explicit_rdpem_enabled_flag, intra_smoothing_disabled_flag, persistent_rice_adaptation_enabled_flag, and log2_max_transform_skip_block_size_minus2	extended_precision_processing_flag	chroma_qp_offset_list_enabled_flag
Scalable Monochrome	0	0	0	0	0
Scalable Monochrome 12	0	0..4	0	0	0
Scalable Monochrome 16	0	–	–	–	0
Scalable Main 4:4:4	–	0	–	0	–

In the remainder of this clause and clause H.11.2.1, all syntax elements in the `profile_tier_level()` syntax structure refer to those in the `profile_tier_level()` syntax structure associated with the layer.

Conformance of a layer in an output operation point associated with an OLS in a bitstream for the scalable format range extensions profiles is indicated as follows:

- If `OpTid` of the output operation point is equal to `vps_max_sub_layer_minus1`, the conformance is indicated by `general_profile_idc` being equal to 10 or `general_profile_compatibility_flag[10]` being equal to 1, with the additional indications specified in Table H.4 for the general constraint flags.
- Otherwise (`OpTid` of the output operation point is less than `vps_max_sub_layer_minus1`), the conformance is indicated by `sub_layer_profile_idc[OpTid]` being equal to 10 or `sub_layer_profile_compatibility_flag[OpTid][10]` being equal to 1, with the additional indications specified in Table H.4 for the flags associated with the index `OpTid`.

All other combinations of `general_max_14bit_constraint_flag`, `general_max_12bit_constraint_flag`, `general_max_10bit_constraint_flag`, `general_max_8bit_constraint_flag`, `general_max_422chroma_constraint_flag`, `general_max_420chroma_constraint_flag`, `general_max_monochrome_constraint_flag`, `general_intra_constraint_flag`, `general_one_picture_only_constraint_flag`, and `general_lower_bit_rate_constraint_flag` with `general_profile_idc` equal to 10 or

general_profile_compatibility_flag[10] equal to 1 are reserved for future use by ITU-T | ISO/IEC. All other combinations of sub_layer_max_14bit_constraint_flag[OpTid], sub_layer_max_12bit_constraint_flag[OpTid], sub_layer_max_10bit_constraint_flag[OpTid], sub_layer_max_8bit_constraint_flag[OpTid], sub_layer_max_422chroma_constraint_flag[OpTid], sub_layer_max_420chroma_constraint_flag[OpTid], sub_layer_max_monochrome_constraint_flag[OpTid], sub_layer_intra_constraint_flag[OpTid], sub_layer_one_picture_only_constraint_flag[OpTid], and sub_layer_lower_bit_rate_constraint_flag[OpTid] with sub_layer_profile_idc[OpTid] equal to 10 or sub_layer_profile_compatibility_flag[OpTid][10] equal to 1 are reserved for future use by ITU-T | ISO/IEC. Such combinations shall not be present in bitstreams conforming to this Specification. However, decoders conforming to the scalable format range extensions profiles shall allow other combinations as specified below in this clause to occur in the bitstream.

Table H.4 – Bitstream indications for conformance to scalable range extensions profiles

Profile for which the bitstream indicates conformance	general_max_14bit_constraint_flag or sub_layer_max_14bit_constraint_flag[OpTid]	general_max_12bit_constraint_flag or sub_layer_max_12bit_constraint_flag[OpTid]	general_max_10bit_constraint_flag or sub_layer_max_10bit_constraint_flag[OpTid]	general_max_8bit_constraint_flag or sub_layer_max_8bit_constraint_flag[OpTid]	general_max_422chroma_constraint_flag or sub_layer_max_422chroma_constraint_flag[OpTid]	general_max_420chroma_constraint_flag or sub_layer_max_420chroma_constraint_flag[OpTid]	general_max_monochrome_constraint_flag or sub_layer_max_monochrome_constraint_flag[OpTid]	general_intra_constraint_flag or sub_layer_intra_constraint_flag[OpTid]	general_one_picture_only_constraint_flag or sub_layer_one_picture_only_constraint_flag[OpTid]	general_lower_bit_rate_constraint_flag or sub_layer_lower_bit_rate_constraint_flag[OpTid]
Scalable Monochrome	1	1	1	1	1	1	1	0	0	1
Scalable Monochrome 12	1	1	0	0	1	1	1	0	0	1
Scalable Monochrome 16	0	0	0	0	1	1	1	0	0	1
Scalable Main 4:4:4	1	1	1	1	0	0	0	0	0	1

H.11.2 Tiers and levels

H.11.2.1 General tier and level limits

For purposes of comparison of tier capabilities, the tier with general_tier_flag or sub_layer_tier_flag[i] equal to 0 is considered to be a lower tier than the tier with general_tier_flag or sub_layer_tier_flag[i] equal to 1.

For purposes of comparison of level capabilities, a particular level of a specific tier is considered to be a lower level than some other level of the same tier when the value of the general_level_idc or sub_layer_level_idc[i] of the particular level is less than that of the other level.

The following is specified for expressing the constraints in this clause and clause H.11.2.2:

- For the Scalable Main profile, the value of each of the variables CpbVclFactor, CpbNalFactor, FormatCapabilityFactor and MinCrScaleFactor is the same as that specified in Table A.10 for the Main profile. For the Scalable Main 10 profile, the value of each of these variables is the same as that specified in Table A.10 for the Main 10 profile.
- For the Scalable Monochrome profile, the value of each of the variables CpbVclFactor, CpbNalFactor, FormatCapabilityFactor, and MinCrScaleFactor is the same as that specified in Table A.10 for the Monochrome profile.
- For the Scalable Monochrome 12 profile, the value of each of the variables CpbVclFactor, CpbNalFactor, FormatCapabilityFactor, and MinCrScaleFactor is the same as that specified in Table A.10 for the Monochrome 12 profile.

- For the Scalable Monochrome 16 profile, the value of each of the variables CpbVclFactor, CpbNalFactor, FormatCapabilityFactor, and MinCrScaleFactor is the same as that specified in Table A.10 for the Monochrome 16 profile.
- For the Scalable Main 4:4:4 profile, the value of each of the variables CpbVclFactor, CpbNalFactor, FormatCapabilityFactor, and MinCrScaleFactor is the same as that specified in Table A.10 for the Main 4:4:4 profile.
- Let access unit n be the n -th access unit in decoding order, with the first access unit being access unit 0 (i.e., the 0-th access unit).
- Let the variable fR be set equal to $1 \div 300$.
- Let the variable $olsIdx$ be the index of the OLS.
- For each layer with nuh_layer_id equal to $currLayerId$, let the variable $layerSizeInSamplesY$ be derived as follows:

$$layerSizeInSamplesY = pic_width_vps_in_luma_samples * pic_height_vps_in_luma_samples \quad (H-121)$$

where $pic_width_vps_in_luma_samples$ and $pic_height_vps_in_luma_samples$ are found in the $vps_rep_format_idx[LayerIdxInVps[currLayerId]]$ -th $rep_format()$ syntax structure in the VPS.

Each layer with nuh_layer_id equal to $currLayerId$ conforming to a profile at a specified tier and level shall obey the following constraints for each bitstream conformance test as specified in clause F.13, where "access unit" is used to denote the picture unit in the layer and the CPB is understood to be the BPB:

- a) The value of $layerSizeInSamplesY$ shall be less than or equal to $MaxLumaPs$, where $MaxLumaPs$ is specified in Table A.8 for the tier and level of the layer.
- b) The value of $pic_width_vps_in_luma_samples$ of the $vps_rep_format_idx[LayerIdxInVps[currLayerId]]$ -th $rep_format()$ syntax structure in the VPS shall be less than or equal to $Sqrt(MaxLumaPs * 8)$.
- c) The value of $pic_height_vps_in_luma_samples$ of the $vps_rep_format_idx[LayerIdxInVps[currLayerId]]$ -th $rep_format()$ syntax structure in the VPS shall be less than or equal to $Sqrt(MaxLumaPs * 8)$.
- d) The value of $max_vps_dec_pic_buffering_minus1[olsIdx][LayerIdxInVps[currLayerId]][HighestTid]$ shall be less than or equal to $MaxDpbSize$ as derived by Equation A-2, with $PicSizeInSamplesY$ being replaced with $layerSizeInSamplesY$, for the tier and level of the layer.
- e) For level 5 and higher levels, the value of $CtbSizeY$ for the layer shall be equal to 32 or 64.
- f) The value of $NumPicTotalCurr$ for each picture in the layer shall be less than or equal to 8.
- g) When decoding each coded picture in the layer, the value of $num_tile_columns_minus1$ shall be less than $MaxTileCols$ and $num_tile_rows_minus1$ shall be less than $MaxTileRows$, where $MaxTileCols$ and $MaxTileRows$ are specified in Table A.8 for the tier and level of the layer.
- h) For the VCL HRD parameters of the layer, $CpbSize[i]$ shall be less than or equal to $CpbVclFactor * MaxCPB$ for at least one of the delivery schedules identified by $bsp_sched_idx[olsIdx][0][HighestTid][combIdx][LayerIdxInVps[currLayerId]]$ for $combIdx$ ranging from 0 to $num_bsp_schedules_minus1[olsIdx][0][HighestTid]$, inclusive, where $CpbSize[i]$ is specified in clause F.13.1 and $MaxCPB$ is specified in Table A.8 for the tier and level of the layer in units of $CpbVclFactor$ bits.
- i) For the NAL HRD parameters of the layer, $CpbSize[i]$ shall be less than or equal to $CpbNalFactor * MaxCPB$ for at least one of the delivery schedules identified by $bsp_sched_idx[olsIdx][0][HighestTid][combIdx][LayerIdxInVps[currLayerId]]$ for $combIdx$ ranging from 0 to $num_bsp_schedules_minus1[olsIdx][0][HighestTid]$, inclusive, where $CpbSize[i]$ is specified in clause F.13.1 and $MaxCPB$ is specified in Table A.8 for the tier and level of the layer in units of $CpbNalFactor$ bits.

Table A.8 specifies the limits for each level of each tier for levels other than level 8.5.

A tier and level to which a layer in an output operation point associated with an OLS in a bitstream conforms are indicated by the syntax elements $general_tier_flag$ and $general_level_idc$ if $OpTid$ of the output layer set is equal to

vps_max_sub_layer_minus1, and by the syntax elements sub_layer_tier_flag[OpTid] and sub_layer_level_idc[OpTid] otherwise, as follows:

- If the specified level is not level 8.5, general_tier_flag or sub_layer_tier_flag[OpTid] equal to 0 indicates conformance to the Main tier, and general_tier_flag or sub_layer_tier_flag[OpTid] equal to 1 indicates conformance to the High tier, according to the tier constraints specified in Table A.8, and general_tier_flag and sub_layer_tier_flag[OpTid] shall be equal to 0 for levels below level 4 (corresponding to the entries in Table A.8 marked with "-"). Otherwise (the specified level is level 8.5), it is a requirement of bitstream conformance that general_tier_flag and sub_layer_tier_flag[OpTid] shall be equal to 1 and the value 0 for general_tier_flag and sub_layer_tier_flag[OpTid] is reserved for future use by ITU-T | ISO/IEC and decoders shall ignore the value of general_tier_flag and sub_layer_tier_flag[OpTid].
- general_level_idc and sub_layer_level_idc[OpTid] shall be set equal to a value of 30 times the level number specified in Table A.8.

H.11.2.2 Profile-specific tier and level limits for the Scalable Main, Scalable Main 10 and scalable format range extensions profiles

The following is specified for expressing the constraints in this clause:

- The variable HbrFactor is set equal to 1.
- The variable BrVclFactor is set equal to CpbVclFactor * HbrFactor.
- The variable BrNalFactor is set equal to CpbNalFactor * HbrFactor.
- The variable MinCr is set equal to MinCrBase * MinCrScaleFactor ÷ HbrFactor, where MinCrBase is specified in Table A.9.

Each layer conforming to the Scalable Main or Scalable Main 10 profiles or a scalable format range extensions profile at a specified tier and level shall obey the following constraints for each conformance test as specified in clause F.13, where "access unit" is used to denote the picture unit in the layer and the CPB is understood to be the BPB:

- a) The nominal removal time of access unit n (with n greater than 0) from the CPB, as specified in clause F.13.2.3, shall satisfy the constraint that $AuNominalRemovalTime[n] - AuCpbRemovalTime[n - 1]$ is greater than or equal to $\text{Max}(\text{layerSizeInSamplesY} \div \text{MaxLumaSr}, fR)$, where $\text{layerSizeInSamplesY}$ is the value of $\text{layerSizeInSamplesY}$ for access unit $n - 1$ and MaxLumaSr is the value specified in Table A.9 that applies to access unit $n - 1$ for the tier and level of the layer.
- b) The difference between consecutive output times of pictures in different access units, as specified in clause F.13.3.3 shall satisfy the constraint that $\text{DpbOutputInterval}[n]$ is greater than or equal to $\text{Max}(\text{layerSizeInSamplesY} \div \text{MaxLumaSr}, fR)$, where $\text{layerSizeInSamplesY}$ is the value of $\text{layerSizeInSamplesY}$ of access unit n and MaxLumaSr is the value specified in Table A.9 for access unit n for the tier and level of the layer, provided that access unit n is an access unit that has a picture that is output and is not the last of such access units.
- c) The removal time of access unit 0 shall satisfy the constraint that the number of coded slice segments in access unit 0 is less than or equal to $\text{Min}(\text{Max}(1, \text{MaxSliceSegmentsPerPicture} * \text{MaxLumaSr} / \text{MaxLumaPs} * (\text{AuCpbRemovalTime}[0] - \text{AuNominalRemovalTime}[0]) + \text{MaxSliceSegmentsPerPicture} * \text{layerSizeInSamplesY} / \text{MaxLumaPs}), \text{MaxSliceSegmentsPerPicture})$, for the value of $\text{layerSizeInSamplesY}$ of access unit 0, where $\text{MaxSliceSegmentsPerPicture}$, MaxLumaPs and MaxLumaSr are the values specified in Table A.8 and Table A.9 for the tier and level of the layer.
- d) The difference between consecutive CPB removal times of access units n and $n - 1$ (with n greater than 0) shall satisfy the constraint that the number of slice segments in access unit n is less than or equal to $\text{Min}(\text{Max}(1, \text{MaxSliceSegmentsPerPicture} * \text{MaxLumaSr} / \text{MaxLumaPs} * (\text{AuCpbRemovalTime}[n] - \text{AuCpbRemovalTime}[n - 1])), \text{MaxSliceSegmentsPerPicture})$, where $\text{MaxSliceSegmentsPerPicture}$, MaxLumaPs and MaxLumaSr are the values specified in Table A.8 and Table A.9 that apply to access unit n for the tier and level of the layer.
- e) For the VCL HRD parameters for the layer, $\text{BitRate}[i]$ shall be less than or equal to $\text{BrVclFactor} * \text{MaxBR}$ for at least one of the delivery schedules identified by $\text{bsp_sched_idx}[\text{olsIdx}][0][\text{HighestTid}][\text{combIdx}][\text{LayerIdxInVps}[\text{currLayerId}]]$ for combIdx ranging from 0 to $\text{num_bsp_schedules_minus1}[\text{olsIdx}][0][\text{HighestTid}]$, inclusive, where $\text{BitRate}[i]$ is specified in clause F.13.1 and MaxBR is specified in Table A.9 in units of BrVclFactor bits/s for the tier and level of the layer.
- f) For the NAL HRD parameters for the layer, $\text{BitRate}[i]$ shall be less than or equal to $\text{BrNalFactor} * \text{MaxBR}$ for at least one of the delivery schedules identified by $\text{bsp_sched_idx}[\text{olsIdx}][0][\text{HighestTid}][\text{combIdx}][\text{LayerIdxInVps}[\text{currLayerId}]]$ for combIdx ranging from 0 to $\text{num_bsp_schedules_minus1}[\text{olsIdx}][0]$

[HighestTid], inclusive, where BitRate[i] is specified in clause F.13.1 and MaxBR is specified in Table A.9 in units of BrNalFactor bits/s for the tier and level of the layer.

- g) The sum of the NumBytesInNalUnit variables for access unit 0 shall be less than or equal to $\text{FormatCapabilityFactor} * (\text{Max}(\text{layerSizeInSamplesY}, \text{fR} * \text{MaxLumaSr}) + \text{MaxLumaSr} * (\text{AuCpbRemovalTime}[0] - \text{AuNominalRemovalTime}[0])) \div \text{MinCr}$ for the value of layerSizeInSamplesY of access unit 0, where MaxLumaSr is specified in Table A.9, and both MaxLumaSr and FormatCapabilityFactor are the values that apply to access unit 0 for the tier and level of the layer.
- h) The sum of the NumBytesInNalUnit variables for access unit n (with n greater than 0) shall be less than or equal to $\text{FormatCapabilityFactor} * \text{MaxLumaSr} * (\text{AuCpbRemovalTime}[n] - \text{AuCpbRemovalTime}[n-1]) \div \text{MinCr}$, where MaxLumaSr is specified in Table A.9, and both MaxLumaSr and FormatCapabilityFactor are the values that apply to access unit n for the tier and level of the layer.
- i) The removal time of access unit 0 shall satisfy the constraint that the number of tiles in coded pictures in access unit 0 is less than or equal to $\text{Min}(\text{Max}(1, \text{MaxTileCols} * \text{MaxTileRows} * 120 * (\text{AuCpbRemovalTime}[0] - \text{AuNominalRemovalTime}[0]) + \text{MaxTileCols} * \text{MaxTileRows} * \text{PicSizeInSamplesY} / \text{MaxLumaPs}), \text{MaxTileCols} * \text{MaxTileRows})$, for the value of layerSizeInSamplesY of access unit 0, where MaxTileCols and MaxTileRows are the values specified in Table A.8 that apply to access unit 0 for the tier and level of the layer.
- j) The difference between consecutive CPB removal times of access units n and n – 1 (with n greater than 0) shall satisfy the constraint that the number of tiles in coded pictures in access unit n is less than or equal to $\text{Min}(\text{Max}(1, \text{MaxTileCols} * \text{MaxTileRows} * 120 * (\text{AuCpbRemovalTime}[n] - \text{AuCpbRemovalTime}[n-1])), \text{MaxTileCols} * \text{MaxTileRows})$, where MaxTileCols and MaxTileRows are the values specified in Table A.8 that apply to access unit n for the tier and level of the layer.

H.11.3 Decoder capabilities

When a decoder conforms to any profile specified in Annex H, it shall also have the INBLD capability specified in clause F.11.1.

Clause F.11.2 specifies requirements for a decoder conforming to any profile specified in this annex.

H.12 Byte stream format

The specifications in clause F.12 apply.

H.13 Hypothetical reference decoder

The specifications in clause F.13 and its subclauses apply.

H.14 Supplemental enhancement information

The specifications in Annex D and clause F.14 and their subclauses apply.

H.15 Video usability information

The specifications in clause F.15 and its subclauses apply.

Annex I

3D high efficiency video coding

(This annex forms an integral part of this Recommendation | International Standard.)

I.1 Scope

This annex specifies syntax, semantics, and decoding processes for 3D high efficiency video coding that use the syntax, semantics, and decoding processes specified in clauses 2-10 and Annexes A-G. This annex also specifies profiles, tiers, and levels for 3D high efficiency video coding.

I.2 Normative references

The list of normative references in clause G.2 apply.

I.3 Definitions

For the purpose of this annex, the following definitions apply in addition to the definitions in clause G.3. These definitions are either not present in clause G.3 or replace definitions in clause G.3.

- I.3.1 depth intra contour prediction:** A *prediction* of a *partition pattern* for a *prediction block* in a *picture* of a *depth layer* derived from samples of a *picture* included in the same *access unit* and in the *texture layer* of the same *view*.
- I.3.2 depth layer:** A *layer* with a *nuh_layer_id* value equal to *i*, such that *DepthLayerFlag[i]* is equal to 1 and *DependencyId[i]* and *AuxId[i]* are equal to 0.
- I.3.3 depth look-up table:** A list containing *depth values*.
- I.3.4 depth value:** A sample value of a *decoded picture* of a *depth layer*.
- I.3.5 disparity vector:** A *motion vector* used for inter-view prediction.
- I.3.6 inter-component prediction:** An *inter-layer prediction* where the *reference pictures* are associated with a *DepthFlag* value different from the *DepthFlag* value of the current *picture*.
- I.3.7 inter-view prediction:** An *inter-layer prediction* where the *reference pictures* are associated with *reference view order index* values different from the *ViewIdx* value of the current *picture*.
- I.3.8 intra prediction:** A *prediction* derived from only data elements (e.g., sample values) of the same *decoded slice* and additionally *may* be using *depth intra contour prediction*.
- I.3.9 partition pattern:** An MxM (M-column by M-row) array of *flags* defining two *sub-block partitions* of an MxM *prediction block*.
- I.3.10 prediction block:** A rectangular MxN *block* of samples on which either the same *prediction* or *partitioning* in *sub-block partitions* is applied.
- I.3.11 reference view order index:** A *ViewIdx* value associated with a *reference picture* used for *inter-view prediction*.
- I.3.12 sub-block partition:** A subset of samples of a *prediction block* on which the same *prediction* is applied.
- I.3.13 texture layer:** A *layer* with a *nuh_layer_id* value equal to *i*, such that *DepthLayerFlag[i]*, *DependencyId[i]*, and *AuxId[i]* are equal to 0.

I.4 Abbreviations

The specifications in clause G.4 apply.

I.5 Conventions

The specifications in clause G.5 apply.

I.6 Bitstream and picture formats, partitionings, scanning processes, and neighbouring relationships

I.6.1 Bitstream formats

The specifications in clause 6.1 apply.

I.6.2 Source, decoded, and output picture formats

The specifications in clause 6.2 apply.

I.6.3 Partitioning of pictures, slices, slice segments, tiles, CTUs, and CTBs

The specifications in clause 6.3 and its subclauses apply.

I.6.4 Availability processes

The specifications in clause 6.4 apply.

I.6.5 Scanning processes

The specifications in clause 6.5 and its subclauses apply.

I.6.6 Derivation process for a wedgelet partition pattern table

NOTE – Tables and values resulting from this process are independent of any information contained in the bitstream.

The list `WedgePatternTable[log2BlkSize]` of partition patterns of size $(1 \ll \log2BlkSize) \times (1 \ll \log2BlkSize)$ and the variable `NumWedgePattern[log2BlkSize]` specifying the number of partition patterns in list `WedgePatternTable[log2BlkSize]` are derived as follows:

- For `log2BlkSize` in the range of 2 to 4, inclusive, the following applies:
 - `NumWedgePattern[log2BlkSize]` is set equal to 0.
 - The variable `resShift` is set equal to $(\log2BlkSize == 4) ? 0 : 1$.
 - The variable `wBlkSize` is set equal to $(1 \ll (\log2BlkSize + resShift))$.
 - For `wedgeOri` in the range of 0 to 5, inclusive, the following applies:
 - The variable `posEnd` is set equal to `NumWedgePattern[log2BlkSize]`.
 - If `wedgeOri` is equal to 0 or 4, the following applies:
 - The variables `sizeScaleS` and `sizeScaleE` are derived as follows:
$$sizeScaleS = (\log2BlkSize > 3) ? 2 : 1 \quad (I-1)$$
$$sizeScaleE = (\text{wedgeOri} < 4 \ \&\& \ \log2BlkSize > 3) ? 2 : 1 \quad (I-2)$$
 - For `m` in the range of 0 to $(wBlkSize / sizeScaleS - 1)$, inclusive, the following applies:
 - For `n` in the range of 0 to $(wBlkSize / sizeScaleE - 1)$, inclusive, the following applies:
 - The wedgelet partition pattern generation process as specified in clause I.6.6.1 is invoked with `patternSize` equal to $(1 \ll \log2BlkSize)$, the variable `resShift`, the variable `wedgeOri`, the variable (xS, yS) equal to $(m * sizeScaleS, 0)$, the variable (xE, yE) equal to $(\text{wedgeOri} == 0) ? (0, n * sizeScaleE) : (n * sizeScaleE, wBlkSize - 1)$ as inputs, and the output is the partition pattern `curWedgePattern`.
 - The wedgelet partition pattern table insertion process as specified in clause I.6.6.2 is invoked with the variable `log2BlkSize` and the partition pattern `curWedgePattern` as inputs.
 - Otherwise (`wedgeOri` is equal to 1, 2, 3, or 5), the following applies:
 - For `curPos` in the range of `posStart` to `posEnd - 1`, inclusive, the following applies:
 - The partition pattern `curWedgePattern[x][y]` is derived as follows:
$$\begin{aligned} &\text{for}(y = 0; y < (1 \ll \log2BlkSize); y++) \\ &\quad \text{for}(x = 0; x < (1 \ll \log2BlkSize); x++) \\ &\quad \quad \text{curWedgePattern}[x][y] = 1 - \\ &\quad \quad \quad \text{WedgePatternTable}[\log2BlkSize][\text{curPos}][y][(1 \ll \log2BlkSize) - 1 - x] \end{aligned} \quad (I-3)$$
 - The variable `posStart` is set equal to `posEnd`.
 - `NumWedgePattern[5]` is set equal to `NumWedgePattern[4]`.
 - For `k = 0..NumWedgePattern[5] - 1`, the following applies:
 - For `x, y = 0..(1 << 5) - 1`, the following applies:
$$\text{WedgePatternTable}[5][k][x][y] = \text{WedgePatternTable}[4][k][x >> 1][y >> 1] \quad (I-4)$$

I.6.6.1 Wedgelet partition pattern generation process

Inputs to this process are:

- a variable `patternSize` specifying the partition pattern size,
- a variable `resShift` specifying the precision of the partition pattern start and end locations relative to `patternSize`,
- a variable `wedgeOri` specifying the orientation of the partition pattern,
- a location (`xS`, `yS`) specifying the boundary start of a sub-block partition,
- a location (`xE`, `yE`) specifying the boundary end of a sub-block partition.

Output of this process is the partition pattern `wedgePattern[x][y]` of size (`patternSize`)x(`patternSize`).

The values of the partition pattern `wedgePattern[x][y]` are derived as specified by the following ordered steps:

1. For `x, y = 0..patternSize - 1`, `wedgePattern[x][y]` is set equal to 0.
2. The samples of the partition pattern `wedgePattern` that form a line between (`xS`, `yS`) and (`xE`, `yE`) are set equal to 1 as follows:

```
( x0, y0 ) = ( xS, yS )
( x1, y1 ) = ( xE, yE )
if( abs( yE - yS ) > abs( xE - xS ) ) {
    ( x0, y0 ) = Swap( x0, y0 )
    ( x1, y1 ) = Swap( x1, y1 )
}
if( x0 > x1 ) {
    ( x0, x1 ) = Swap( x0, x1 )
    ( y0, y1 ) = Swap( y0, y1 )
}
sumErr = 0
posY = y0
for( posX = x0; posX <= x1; posX++ ) {
    if( abs( yE - yS ) > abs( xE - xS ) )
        wedgePattern[ posY >> resShift ][ posX >> resShift ] = 1
    else
        wedgePattern[ posX >> resShift ][ posY >> resShift ] = 1
    sumErr += ( abs( y1 - y0 ) << 1 )
    if( sumErr >= ( x1 - x0 ) ) {
        posY += ( y0 < y1 ) ? 1 : -1
        sumErr -= ( x1 - x0 ) << 1
    }
}
```

(I-5)

3. The samples of `wedgePattern` are modified as follows:

```
for( y = 0; y <= ( yE >> resShift ); y++ )
    for( x = 0; ( x <= patternSize - 1 ) && ( wedgePattern[ x ][ y ] == 0 ); x++ )
        wedgePattern[ x ][ y ] = 1
```

(I-6)

I.6.6.2 Wedgelet partition pattern table insertion process

Inputs to this process are:

- a variable `log2BlkSize` specifying the partition pattern size,
- a partition pattern `wedgePattern[x][y]`, with `x, y = 0..(1 << log2BlkSize) - 1`.

The variable `validPatternFlag` is set equal to 0 and the following applies:

1. For `x, y = 0..(1 << log2BlkSize) - 1`, the following applies:
 - When `wedgePattern[x][y]` is not equal to `wedgePattern[0][0]`, `validPatternFlag` is set equal to 1.
2. For `k = 0..NumWedgePattern[log2BlkSize] - 1`, the following applies:
 - The variable `patIdenticalFlag` is set equal to 1.
 - For `x, y = 0..(1 << log2BlkSize) - 1`, the following applies:

- When `wedgePattern[x][y]` is not equal to `WedgePatternTable[log2BlkSize][k][x][y]`, `patIdenticalFlag` is set equal to 0.
 - When `patIdenticalFlag` is equal to 1, `validPatternFlag` is set equal to 0.
3. For `k = 0..NumWedgePattern[log2BlkSize] – 1`, the following applies:
- The variable `patInvIdenticalFlag` is set equal to 1.
 - For `x, y = 0..(1 << log2BlkSize) – 1`, the following applies:
 - When `wedgePattern[x][y]` is equal to `WedgePatternTable[log2BlkSize][k][x][y]`, `patInvIdenticalFlag` is set equal to 0.
 - When `patInvIdenticalFlag` is equal to 1, `validPatternFlag` is set equal to 0.

When `validPatternFlag` is equal to 1, the following applies:

- The pattern `WedgePatternTable[log2BlkSize][NumWedgePattern[log2BlkSize]]` is set equal to `wedgePattern`.
- The value of `NumWedgePattern[log2BlkSize]` is incremented by one.

I.7.4.2.3 Encapsulation of an SODB within an RBSP (informative)

The specifications in clause F.7.4.2.3 apply.

I.7.4.2.4 Order of NAL units and association to coded pictures, access units, and coded video sequences

The specifications in clause F.7.4.2.4 and all its subclauses apply.

I.7.4.3 Raw byte sequence payloads, trailing bits, and byte alignment semantics

I.7.4.3.1 Video parameter set RBSP semantics

The specifications in clause F.7.4.3.1 apply with the following modifications and additions:

vps_extension2_flag equal to 0 specifies that no **vps_3d_extension()** syntax structure and no **vps_extension_data_flag** syntax elements are present in the VPS RBSP syntax structure. **vps_extension2_flag** equal to 1 specifies that the **vps_3d_extension()** syntax structure and **vps_extension_data_flag** syntax elements may be present in the VPS RBSP syntax structure. When **MaxLayersMinus1** is greater than 0, **vps_extension2_flag** shall be equal to 1.

vps_3d_extension_flag equal to 0 specifies that no **vps_3d_extension()** syntax structure is present in the VPS RBSP syntax structure. **vps_3d_extension_flag** equal to 1 specifies that the **vps_3d_extension()** syntax structure is present in the VPS RBSP syntax structure. When **MaxLayersMinus1** is greater than 0, **vps_3d_extension_flag** shall be equal to 1.

vps_3d_extension_alignment_bit_equal_to_one shall be equal to 1.

vps_extension3_flag equal to 0 specifies that no **vps_extension_data_flag** syntax elements are present in the VPS RBSP syntax structure. **vps_extension3_flag** shall be equal to 0 in bitstreams conforming to this version of this Specification. The value of 1 for **vps_extension3_flag** is reserved for future use by ITU-T | ISO/IEC. Decoders conforming to this version of this Specification shall ignore all data that follow the value 1 for **vps_extension3_flag** in a VPS RBSP.

vps_extension_data_flag may have any value. Its presence and value do not affect decoder conformance to profiles specified in Annexes A, G, H, or I. Decoders conforming to a profile specified in Annexes A, G, H, or I shall ignore all **vps_extension_data_flag** syntax elements.

1.7.4.3.1.1 Video parameter set extension semantics

The specifications in clause F.7.4.3.1.1 apply with the following additions and modifications:

direct_dependency_type[i][j] indicates the type of dependency between the layer **predLayer** with **nuh_layer_id** equal **layer_id_in_nuh**[i] and the layer **refLayer** with **nuh_layer_id** equal to **layer_id_in_nuh**[j]. ((**direct_dependency_type**[i][j] + 1) & 0x1) greater than 0 specifies that samples of **refLayer** may be used for inter-layer prediction of **predLayer**. ((**direct_dependency_type**[i][j] + 1) & 0x1) equal to 0 specifies that samples of **refLayer** are not used for inter-layer prediction of **predLayer**. ((**direct_dependency_type**[i][j] + 1) & 0x2) greater than 0 specifies that motion vectors of **refLayer** may be used for inter-layer prediction of **predLayer**. ((**direct_dependency_type**[i][j] + 1) & 0x2) equal to 0 specifies that motion vectors of **refLayer** are not used for inter-layer prediction of **predLayer**. ((**direct_dependency_type**[i][j] + 1) & 0x4) greater than 0 specifies that coding quadtree and coding unit partitioning information of **refLayer** may be used for inter-layer prediction of **predLayer**. ((**direct_dependency_type**[i][j] + 1) & 0x4) equal to 0 specifies that coding quadtree and coding unit partitioning information of **refLayer** are not used for inter-layer prediction of the **predLayer**.

The length of the **direct_dependency_type**[i][j] syntax element is **direct_dep_type_len_minus2** + 2 bits. Although the value of **direct_dependency_type**[i][j] shall be in the range of 0 to 2, inclusive, when **predLayer** conforms to a profile specified in Annexes A, G, or H, and in the range of 0 to 6, inclusive, when the **predLayer** conforms to a profile specified in Annex I, decoders shall allow values of **direct_dependency_type**[i][j] in the range of 0 to $2^{32} - 2$, inclusive, to appear in the syntax.

The list **ViewOIdxList**[idx] is derived as follows:

```

idx = 0
ViewOIdxList[ idx++ ] = 0
for( i = 1; i <= MaxLayersMinus1; i++ ) {
    newViewFlag = 1
    for( j = 0; j < i; j++ )
        if( ViewOrderIdx[ layer_id_in_nuh[ i ] ] == ViewOrderIdx[ layer_id_in_nuh[ j ] ] )
            newViewFlag = 0
    if( newViewFlag )
        ViewOIdxList[ idx++ ] = ViewOrderIdx[ i ]
}

```

(I-7)

The variables **NumRefListLayers**[iNuhLid] and **IdRefListLayer**[iNuhLid] are derived as follows:

```

for( i = 0; i <= MaxLayersMinus1; i++ ) {
    iNuhLid = layer_id_in_nuh[ i ]
    NumRefListLayers[ iNuhLid ] = 0
    for( j = 0; j < NumDirectRefLayers[ iNuhLid ]; j++ ) {
        jNuhLid = IdDirectRefLayer[ iNuhLid ][ j ]
        if( DepthLayerFlag[ iNuhLid ] == DepthLayerFlag[ jNuhLid ] )
            IdRefListLayer[ iNuhLid ][ NumRefListLayers[ iNuhLid ]++ ] = jNuhLid
    }
}

```

(I-8)

The variables **ViewCompLayerPresentFlag**[iViewOIdx][depFlag] and **ViewCompLayerId**[iViewOIdx][depFlag] are derived as follows:

```

for( depFlag = 0; depFlag <= 1; depFlag++ )
    for( i = 0; i < NumViews; i++ ) {
        iViewOIdx = ViewOIdxList[ i ]
        layerId = -1
        for( j = 0; j <= MaxLayersMinus1; j++ ) {
            jNuhLid = layer_id_in_nuh[ j ]
            if( DepthLayerFlag[ jNuhLid ] == depFlag && ViewOrderIdx[ jNuhLid ] == iViewOIdx
                && DependencyId[ jNuhLid ] == 0 && AuxId[ jNuhLid ] == 0 )
                layerId = jNuhLid
        }
    }

```

(I-9)

```

    }
    ViewCompLayerPresentFlag[ iViewOIdx ][ depFlag ] = ( layerId != -1 )
    ViewCompLayerId[ iViewOIdx ][ depFlag ] = layerId
}

```

The function ViewIdx(picX) is specified as follows:

$$\text{ViewIdx(picX)} = \text{ViewIdx of the picture picX} \quad (\text{I-10})$$

The function ViewIdVal(picX) is specified as follows:

$$\text{ViewIdVal(picX)} = \text{view_id_val[ViewIdx(picX)]} \quad (\text{I-11})$$

I.7.4.3.1.2 Representation format semantics

The specifications in clause F.7.4.3.1.2 apply.

I.7.4.3.1.3 DPB size semantics

The specifications in clause F.7.4.3.1.3 apply.

The specifications in clause F.7.4.3.1.4 apply.

I.7.4.3.1.5 Video signal info semantics

The specifications in clause F.7.4.3.1.5 apply.

I.7.4.3.1.6 VPS VUI bitstream partition HRD parameters semantics

The specifications in clause F.7.4.3.1.6 apply.

I.7.4.3.1.7 Video parameter set 3D extension semantics

cp_precision + BitDepth_V – 1 specifies the precision of the vps_cp_scale[i][j] and vps_cp_inv_scale_plus_scale[i][j] syntax elements present in the VPS and the cp_scale[j] and cp_inv_scale_plus_scale[j] syntax elements present in slice headers. The value of cp_precision shall be in the range of 0 to 5, inclusive.

num_cp[i], when cp_in_slice_segment_header_flag[i] is equal to 0, specifies the number of vps_cp_scale[i][j], vps_cp_off[i][j], vps_cp_inv_scale_plus_scale[i][j], and vps_cp_inv_off_plus_off[i][j] syntax elements present for the view with ViewIdx equal to i in the VPS. num_cp[i], when cp_in_slice_segment_header_flag[i] is equal to 1, specifies the number of cp_scale[j], cp_off[j], cp_inv_scale_plus_scale[j], and cp_inv_off_plus_off[j] syntax elements present in slice headers of layers with ViewIdx equal to i.

cp_in_slice_segment_header_flag[i] equal to 1 specifies that the syntax elements vps_cp_scale[i][j], vps_cp_off[i][j], vps_cp_inv_scale_plus_scale[i][j], and vps_cp_inv_off_plus_off[i][j] for the view with ViewIdx equal to i are not present in the VPS and that the syntax elements cp_scale[j], cp_off[j], cp_inv_scale_plus_scale[j], and cp_inv_off_plus_off[j] may be present in slice headers of layers with ViewIdx equal to i. cp_in_slice_segment_header_flag[i] equal to 0 specifies that the vps_cp_scale[i][j], vps_cp_off[i][j], vps_cp_inv_scale_plus_scale[i][j], and vps_cp_inv_off_plus_off[i][j] syntax elements for the view with ViewIdx equal to i are present in the VPS and that the syntax elements cp_scale[j], cp_off[j], cp_inv_scale_plus_scale[j], and cp_inv_off_plus_off[j] are not present in slice headers of layers with ViewIdx equal to i. When not present, the value of cp_in_slice_segment_header_flag[i] is inferred to be equal to 0.

cp_ref_voi[i][m], when cp_in_slice_segment_header_flag[i] is equal to 0, specifies the ViewIdx value j of the view to which the m-th vps_cp_scale[i][j], vps_cp_off[i][j], vps_cp_inv_scale_plus_scale[i][j], and vps_cp_inv_off_plus_off[i][j] syntax element present for the view with ViewIdx equal to i in the VPS is related to. cp_ref_voi[i][m], when cp_in_slice_segment_header_flag[i] is equal to 1, specifies the ViewIdx value j of the view to which the m-th cp_scale[j], cp_off[j], cp_inv_scale_plus_scale[j], and cp_inv_off_plus_off[j] syntax element present in the slice headers of layers with ViewIdx equal to i is related to. The value of cp_ref_voi[i][m] shall be in the range of 0 to 65 535, inclusive. It is a requirement of bitstream conformance that cp_ref_voi[i][x] is not equal to cp_ref_voi[i][y] for any values of x and y in the range of 0 to num_cp[i] – 1, inclusive, when x is not equal to y.

For n and m in the range of 0 to NumViews – 1, inclusive, the variable CpPresentFlag[ViewOIdxList[n]][ViewOIdxList[m]] is set equal to 0 and modified as follows:

```

for( n = 1; n < NumViews; n++ ) {
    i = ViewOIdxList[ n ]
    for( m = 0; m < num_cp[ i ]; m++ )
        CpPresentFlag[ i ][ cp_ref_voi[ i ][ m ] ] = 1
}

```

(I-12)

vps_cp_scale[i][j], **vps_cp_off**[i][j], **vps_cp_inv_scale_plus_scale**[i][j], and **vps_cp_inv_off_plus_off**[i][j] specify parameters for derivation of a horizontal component of a disparity vector from a depth value and may be used to infer the values of the **cp_scale**[j], **cp_off**[j], **cp_inv_scale_plus_scale**[j], and **cp_inv_off_plus_off**[j] syntax elements in slice headers of layers with ViewIdx equal to i. When both a texture layer and a depth layer with ViewIdx equal to i are present, the conversion parameters are associated with the texture layer with ViewIdx equal to i.

I.7.4.3.2 Sequence parameter set RBSP semantics

I.7.4.3.2.1 Sequence parameter set screen content coding extension semantics

The specifications in clause F.7.4.3.2.3 apply.

I.7.4.3.2.2 Sequence parameter set multilayer extension semantic

The specifications in clause F.7.4.3.2.4 apply.

I.7.4.3.2.3 Sequence parameter set 3D extension semantics

iv_di_mc_enabled_flag[d] equal to 1 specifies that the derivation process for inter-view predicted merging candidates and the derivation process for disparity information merging candidates may be used in the decoding process of layers with DepthFlag equal to d. **iv_di_mc_enabled_flag**[d] equal to 0 specifies that derivation process for inter-view predicted merging candidates and the derivation process for disparity information merging candidates is not used in the decoding process of layers with DepthFlag equal to d. When not present, the value of **iv_di_mc_enabled_flag**[d] is inferred to be equal to 0.

iv_mv_scal_enabled_flag[d] equal to 1 specifies that motion vectors used for inter-view prediction may be scaled based on view_id_val values in the decoding process of layers with DepthFlag equal to d. **iv_mv_scal_enabled_flag**[d] equal to 0 specifies that motion vectors used for inter-view prediction are not scaled based on view_id_val values in the decoding process of layers with DepthFlag equal to d. When not present, the value of **iv_mv_scal_enabled_flag**[d] is inferred to be equal to 0.

log2_ivmc_sub_pb_size_minus3[d], when **iv_di_mc_enabled_flag**[d] is equal to 1 and d is equal to 0, is used to derive the minimum size of sub-block partitions used in the derivation process for sub-block partition motion vectors for an inter-layer predicted merging candidate in the decoding process of layers with DepthFlag equal to d. When not present, the value of **log2_ivmc_sub_pb_size_minus3**[d] is inferred to be equal to (CtbLog2SizeY – 3). The value of **log2_ivmc_sub_pb_size_minus3**[d] shall be in the range of (MinCbLog2SizeY – 3) to (CtbLog2SizeY – 3), inclusive.

iv_res_pred_enabled_flag[d] equal to 1 specifies that the **iv_res_pred_weight_idx** syntax element may be present in coding units of layers with DepthFlag equal to d. **iv_res_pred_enabled_flag**[d] equal to 0 specifies that the **iv_res_pred_weight_idx** syntax element is not present coding units of layers with DepthFlag equal to d. When not present, the value of **iv_res_pred_enabled_flag**[d] is inferred to be equal to 0.

vsp_mc_enabled_flag[d] equal to 1 specifies that the derivation process for a view synthesis prediction merging candidate may be used in the decoding process of layers with DepthFlag equal to d. **vsp_mc_enabled_flag**[d] equal to 0 specifies that the derivation process for a view synthesis prediction merging candidate is not used in the decoding process of layers with DepthFlag equal to d. When not present, the value of **vsp_mc_enabled_flag**[d] is inferred to be equal to 0.

dbbp_enabled_flag[d] equal to 1 specifies that the **dbbp_flag** syntax element may be present in coding units of layers with DepthFlag equal to d. **dbbp_enabled_flag**[d] equal to 0 specifies that the **dbbp_flag** syntax element is not present coding units of layers with DepthFlag equal to d. When not present, the value of **dbbp_enabled_flag**[d] is inferred to be equal to 0.

depth_ref_enabled_flag[d] equal to 1 specifies that the derivation process for a depth or disparity sample array from a depth picture may be used in the derivation process for a disparity vector for texture layers in the decoding process of layers with DepthFlag equal to d. **depth_ref_enabled_flag**[d] equal to 0 specifies that derivation process for a depth or disparity sample array from a depth picture is not used in the derivation process for a disparity vector for texture layers in the decoding process of layers with DepthFlag equal to d. When not present, the value of **depth_ref_enabled_flag**[d] is inferred to be equal to 0.

tex_mc_enabled_flag[d] equal to 1 specifies that the derivation process for motion vectors for the texture merge candidate may be used in the decoding process of layers with DepthFlag equal to d. **tex_mc_enabled_flag**[d] equal to 0

specifies that the derivation process for motion vectors for the texture merge candidate is not used in the decoding process of layers with DepthFlag equal to d. When not present, the value of `tex_mc_enabled_flag[d]` is inferred to be equal to 0.

`log2_texmc_sub_pb_size_minus3[d]`, when `tex_mc_enabled_flag[d]` is equal to 1, is used to derive the minimum size of sub-block partitions used in the derivation process for sub-block partition motion vectors for an inter-layer predicted merging candidate in the decoding process of layers with DepthFlag equal to d. The value of `log2_texmc_sub_pb_size_minus3[layerId]` shall be in the range of (`MinCbLog2SizeY - 3`) to (`CtbLog2SizeY - 3`), inclusive.

`intra_contour_enabled_flag[d]` equal to 1 specifies that the intra prediction mode INTRA_CONTOUR using depth intra contour prediction may be used in the decoding process of layers with DepthFlag equal to d. `intra_contour_enabled_flag[d]` equal to 0 specifies that the intra prediction mode INTRA_CONTOUR using depth intra contour prediction is not used in the decoding process of layers with DepthFlag equal to d. When not present, `intra_contour_enabled_flag[d]` is inferred to be equal to 0.

`intra_dc_only_wedge_enabled_flag[d]` equal to 1 specifies that the `dc_only_flag` syntax element may be present in coding units coded in an intra prediction mode of layers with DepthFlag equal to d, and that the intra prediction mode INTRA_WEDGE may be used in the decoding process of layers with DepthFlag equal to d. `intra_dc_only_wedge_enabled_flag[d]` equal to 0 specifies that the `dc_only_flag` syntax element is not present in coding units coded in an intra prediction mode of layers with DepthFlag equal to d and that the intra prediction mode INTRA_WEDGE is not used in the decoding process of layers with DepthFlag equal to d. When not present, the value of `intra_dc_only_wedge_enabled_flag[d]` is inferred to be equal to 0.

`cqt_cu_part_pred_enabled_flag[d]` equal to 1 specifies that coding quadtree and coding unit partitioning information may be inter-component predicted in the decoding process of layers with DepthFlag equal to d. `cqt_cu_part_pred_enabled_flag[d]` equal to 0 specifies that coding quadtree and coding unit partitioning information are not inter-component predicted in the decoding process of layers with DepthFlag equal to d. When not present, the value of `cqt_cu_part_pred_enabled_flag[d]` is inferred to be equal to 0.

`inter_dc_only_enabled_flag[d]` equal to 1 specifies that the `dc_only_flag` syntax element may be present in coding units coded in an inter prediction mode of layers with DepthFlag equal to d. `inter_dc_only_enabled_flag[d]` equal to 0 specifies that the `dc_only_flag` syntax element is not present in coding units coded in an inter prediction mode of layers with DepthFlag equal to d. When not present, the value of `inter_dc_only_enabled_flag[layerId]` is inferred to be equal to 0.

`skip_intra_enabled_flag[d]` equal to 1 specifies that the `skip_intra_flag` syntax element may be present in coding units of layers with DepthFlag equal to d. `skip_intra_enabled_flag[d]` equal to 0 specifies that the `skip_intra_flag` syntax element is not present in coding units of layers with DepthFlag equal to d. When not present, the value of `skip_intra_enabled_flag[layerId]` is inferred to be equal to 0.

I.7.4.3.3 Picture parameter set RBSP semantics

I.7.4.3.3.1 General picture parameter set RBSP semantics

I.7.4.3.3.7 Picture parameter set 3D extension semantics

`dlts_present_flag` equal to 1 specifies that syntax elements for the derivation of depth look-up tables are present in the PPS. `dlts_present_flag` equal to 0 specifies that syntax elements for the derivation of depth look-up tables are not present in the PPS.

The variables NumDepthLayers and DepIdxToLid[j] are derived as follows:

```

j = 0
for( i = 0; i <= MaxLayersMinus1; i++ ) {
    layerId = layer_id_in_nuh[ i ]
    if( DepthLayerFlag[ layerId ] )
        DepIdxToLid[ j++ ] = layerId
}
NumDepthLayers = j

```

(I-13)

pps_depth_layers_minus1 plus 1 specifies the number of depth layers. pps_depth_layers_minus1 shall be equal to NumDepthLayers – 1.

pps_bit_depth_for_depth_layers_minus8 plus 8 specifies the bit depth of the samples in depth layers. It is a requirement of bitstream conformance that pps_bit_depth_for_depth_layers_minus8 shall be equal to bit_depth_luma_minus8 of the SPS the current PPS refers to.

The variable depthMaxValue is set equal to $(1 \ll (\text{pps_bit_depth_for_depth_layers_minus8} + 8)) - 1$.

dlt_flag[i] equal to 1 specifies that a depth look-up table for the layer with nuh_layer_id equal to DepIdxToLid[i] is present in the PPS and used for the decoding of the layer with nuh_layer_id equal to DepIdxToLid[i]. dlt_flag[i] equal to 0 specifies that a depth look-up table is not present for the layer with nuh_layer_id equal to DepIdxToLid[i]. When not present, the value of dlt_flag[i] is inferred to be equal to 0.

For i in the range of 0 to NumDepthLayers – 1, inclusive, the variable DltFlag[DepIdxToLid[i]] is set equal to dlt_flag[i].

dlt_pred_flag[i] equal to 1 indicates that the depth look-up table of the layer with nuh_layer_id equal to DepIdxToLid[i] is predicted from the depth look-up table of the layer with nuh_layer_id equal to DepIdxToLid[0]. dlt_pred_flag[i] equal to 0 indicates that the depth look-up table of the layer with nuh_layer_id equal to DepIdxToLid[i] is not predicted from any other depth look-up table. The value of dlt_pred_flag[0] shall be equal to 0. It is a requirement of bitstream conformance that, when dlt_flag[0] is equal to 0, dlt_pred_flag[i] shall be equal to 0.

dlt_val_flags_present_flag[i] equal to 1 specifies the depth look-up table of the layer with nuh_layer_id equal to DepIdxToLid[i] is derived from dlt_value_flag[i][j] syntax elements. dlt_val_flags_present_flag[i] equal to 0 specifies the depth look-up table of the layer with nuh_layer_id equal to DepIdxToLid[i] is derived from the delta_dlt() syntax structure. When not present, the value of dlt_val_flags_present_flag[i] is inferred to be equal to 0.

dlt_value_flag[i][j] equal to 1 specifies that j is an entry in the depth look-up table of the layer with nuh_layer_id equal to DepIdxToLid[i]. dlt_value_flag[i][j] equal to 0 specifies that j is not an entry in the depth look-up table of the layer with nuh_layer_id equal to DepIdxToLid[i].

When dlt_val_flags_present_flag[i] is equal to 1, the following applies:

- The variable layerId is set equal to DepIdxToLid[i].
- The variables DltVal[layerId][n] and NumValDlt[layerId] of the depth look-up table of the layer with nuh_layer_id equal to layerId are derived as follows:

```

for( n = 0, j = 0; j <= depthMaxValue; j++ )
    if( dlt_value_flag[ i ][ j ] )
        DltVal[ layerId ][ n++ ] = j
NumValDlt[ layerId ] = n

```

(I-14)

1.7.4.3.3.8 Delta depth look-up table semantics

num_val_delta_dlt specifies the number of elements in the list deltaList. The length of num_val_delta_dlt syntax element is pps_bit_depth_for_depth_layers_minus8 + 8 bits.

max_diff specifies the maximum difference between two consecutive elements in the list deltaList. The length of max_diff syntax element is pps_bit_depth_for_depth_layers_minus8 + 8 bits. When not present, the value of max_diff is inferred to be equal to 0.

min_diff_minus1 specifies the minimum difference between two consecutive elements in the list deltaList. min_diff_minus1 shall be in the range of 0 to max_diff – 1, inclusive. The length of the min_diff_minus1 syntax element is $\text{Ceil}(\text{Log2}(\text{max_diff} + 1))$ bits. When not present, the value of min_diff_minus1 is inferred to be equal to (max_diff – 1).

The variable minDiff is set equal to (min_diff_minus1 + 1).

delta_dlt_val0 specifies the 0-th element in the list deltaList. The length of the delta_dlt_val0 syntax element is pps_bit_depth_for_depth_layers_minus8 + 8 bits.

delta_val_diff_minus_min[k] plus minDiff specifies the difference between the k-th element and the (k - 1)-th element in the list deltaList. The length of delta_val_diff_minus_min[k] syntax element is Ceil(Log2(max_diff - minDiff + 1)) bits. When not present, the value of delta_val_diff_minus_min[k] is inferred to be equal to 0.

The list deltaList is derived as follows:

```
deltaList[ 0 ] = delta_dlt_val0
for( k = 1; k < num_val_delta_dlt; k++ )
    deltaList[ k ] = deltaList[ k - 1 ] + delta_val_diff_minus_min[ k ] + minDiff
```

(I-15)

The variables layerId and refLayerId are set equal to DepIdxToLid[i] and DepIdxToLid[0], respectively.

The variables DltVal[layerId][n] and NumValDlt[layerId] of the depth look-up table of the layer with nuh_layer_id equal to layerId are derived as follows:

```
for( n = 0; j = 0; j <= depthMaxValue; j++ ) {
    inRefDltFlag = 0
    if( dlt_pred_flag[ i ] )
        for( k = 0; k < NumValDlt[ refLayerId ]; k++ )
            inRefDltFlag = inRefDltFlag || ( DltVal[ refLayerId ][ k ] == j )
    inUpdateDltFlag = 0
    for( k = 0; k < num_val_delta_dlt; k++ )
        inUpdateDltFlag = inUpdateDltFlag || ( deltaList[ k ] == j )
    if( inRefDltFlag != inUpdateDltFlag )
        DltVal[ layerId ][ n++ ] = j
}
NumValDlt[ layerId ] = n
```

I.7.4.7 Slice segment header semantics

I.7.4.7.1 General slice segment header semantics

The specifications in clause F.7.4.7.1 apply with the following modifications and additions.

The variable `DepthFlag` is set equal to `DepthLayerFlag[nuh_layer_id]` and the variable `ViewIdx` is set equal to `ViewOrderIdx[nuh_layer_id]`.

The list `curCmpLIds` and the variable `numCurCmpLIds` are derived as follows:

`curCmpLIds = DepthFlag ? { nuh_layer_id } : RefPicLayerId`

`numCurCmpLIds = DepthFlag ? 1 : NumActiveRefLayerPics`

The list `inCmpRefViewIds[i]`, the variable `cpAvailableFlag`, and the variable `allRefCmpLayersAvailFlag` are derived as follows:

- The variables `cpAvailableFlag` and `allRefCmpLayersAvailFlag` are set equal to 1.
- For `i` in the range of 0 to `numCurCmpLIds – 1`, inclusive, the following applies:
 - The variable `inCmpRefViewIds[i]` is set equal to `ViewOrderIdx[curCmpLIds[i]]`.
 - When `CpPresentFlag[ViewIdx][inCmpRefViewIds[i]]` is equal to 0, `cpAvailableFlag` is set equal to 0.
 - The variable `refCmpCurLIdAvailFlag` is set equal to 0.
 - When `ViewCompLayerPresentFlag[inCmpRefViewIds[i]][!DepthFlag]` is equal to 1, the following applies:
 - The variable `j` is set equal to `LayerIdxInVps[ViewCompLayerId[inCmpRefViewIds[i]][!DepthFlag]]`.
 - When all of the following conditions are true, `refCmpCurLIdAvailFlag` is set equal to 1:
 - `direct_dependency_flag[LayerIdxInVps[nuh_layer_id]][j]` is equal to 1.
 - `sub_layers_vps_max_minus1[j]` is greater than or equal to `TemporalId`.
 - `TemporalId` is equal to 0 or `max_tid_il_ref_pics_plus1[j][LayerIdxInVps[nuh_layer_id]]` is greater than `TemporalId`.
 - When `refCmpCurLIdAvailFlag` is equal to 0, `allRefCmpLayersAvailFlag` is set equal to 0.

The variable `inCmpPredAvailFlag` is derived as follows:

- If `allRefCmpLayersAvailFlag` is equal to 0, `inCmpPredAvailFlag` is set equal to 0.
- Otherwise (`allRefCmpLayersAvailFlag` is equal to 1), the following applies:
 - If `DepthFlag` is equal to 0, the following applies:

$$\text{inCmpPredAvailFlag} = \text{vsp_mc_enabled_flag}[\text{DepthFlag}] \mid \mid \text{dbbp_enabled_flag}[\text{DepthFlag}] \mid \mid \text{depth_ref_enabled_flag}[\text{DepthFlag}] \quad (\text{I-17})$$

- Otherwise (`DepthFlag` is equal to 1), the following applies:

$$\text{inCmpPredAvailFlag} = \text{intra_contour_enabled_flag}[\text{DepthFlag}] \mid \mid \text{cqt_cu_part_pred_enabled_flag}[\text{DepthFlag}] \mid \mid \text{tex_mc_enabled_flag}[\text{DepthFlag}] \quad (\text{I-18})$$

in_comp_pred_flag equal to 0 specifies that reference pictures required for inter-component prediction of the current picture may not be present and that inter-component prediction of the current picture is disabled. **in_comp_pred_flag** equal to 1 specifies all reference pictures required for inter-component prediction of the current picture are present and that inter-component prediction of the current picture is enabled. When not present, the value of **in_comp_pred_flag** is inferred to be equal to 0.

When `in_comp_pred_flag` is equal to 1, the following applies for `i` in the range of 0 to `numCurCmpLIds - 1`, inclusive:

- It is a requirement of bitstream conformance that there is a picture in the DPB with `PicOrderCntVal` equal to the `PicOrderCntVal` of the current picture, and a `nuh_layer_id` value equal to `ViewCompLayerId[inCmpRefViewIds[i]][!DepthFlag]`.

The variables `IvDiMcEnabledFlag`, `IvMvScalEnabledFlag`, `IvResPredEnabledFlag`, `VspMcEnabledFlag`, `DbbpEnabledFlag`, `DepthRefEnabledFlag`, `TexMcEnabledFlag`, `IntraContourEnabledFlag`, `IntraDcOnlyWedgeEnabledFlag`, `CqtCuPartPredEnabledFlag`, `InterDcOnlyEnabledFlag`, `SkipIntraEnabledFlag` and `DisparityDerivationFlag` are derived as follows:

$$\text{IvDiMcEnabledFlag} = \text{NumRefListLayers}[\text{nuh_layer_id}] > 0 \ \&\& \ \text{iv_di_mc_enabled_flag}[\text{DepthFlag}] \quad (\text{I-19})$$

$$\text{IvMvScalEnabledFlag} = \text{iv_mv_scal_enabled_flag}[\text{DepthFlag}] \ \&\& \ \text{ViewIdx} \neq 0 \quad (\text{I-20})$$

$$\text{IvResPredEnabledFlag} = \text{NumRefListLayers}[\text{nuh_layer_id}] > 0 \ \&\& \ \text{iv_res_pred_enabled_flag}[\text{DepthFlag}] \quad (\text{I-21})$$

$$\text{VspMcEnabledFlag} = \text{NumRefListLayers}[\text{nuh_layer_id}] > 0 \ \&\& \ \text{vsp_mc_enabled_flag}[\text{DepthFlag}] \ \&\& \ \text{in_comp_pred_flag} \ \&\& \ \text{cpAvailableFlag} \quad (\text{I-22})$$

$$\text{DbbpEnabledFlag} = \text{dbbp_enabled_flag}[\text{DepthFlag}] \ \&\& \ \text{in_comp_pred_flag} \quad (\text{I-23})$$

$$\text{DepthRefEnabledFlag} = \text{depth_ref_enabled_flag}[\text{DepthFlag}] \ \&\& \ \text{in_comp_pred_flag} \ \&\& \ \text{cpAvailableFlag} \quad (\text{I-24})$$

$$\text{TexMcEnabledFlag} = \text{tex_mc_enabled_flag}[\text{DepthFlag}] \ \&\& \ \text{in_comp_pred_flag} \quad (\text{I-25})$$

$$\text{IntraContourEnabledFlag} = \text{intra_contour_enabled_flag}[\text{DepthFlag}] \ \&\& \ \text{in_comp_pred_flag} \quad (\text{I-26})$$

$$\text{IntraDcOnlyWedgeEnabledFlag} = \text{intra_dc_only_wedge_enabled_flag}[\text{DepthFlag}] \quad (\text{I-27})$$

$$\text{CqtCuPartPredEnabledFlag} = \text{cqt_cu_part_pred_enabled_flag}[\text{DepthFlag}] \ \&\& \ \text{in_comp_pred_flag} \ \&\& \ \text{slice_type} \neq \text{I} \ \&\& \ !(\text{nal_unit_type} \geq \text{BLA_W_LP} \ \&\& \ \text{nal_unit_type} \leq \text{RSV_IRAP_VCL23}) \quad (\text{I-28})$$

$$\text{InterDcOnlyEnabledFlag} = \text{inter_dc_only_enabled_flag}[\text{DepthFlag}] \quad (\text{I-29})$$

$$\text{SkipIntraEnabledFlag} = \text{skip_intra_enabled_flag}[\text{DepthFlag}] \quad (\text{I-30})$$

$$\text{DisparityDerivationFlag} = \text{IvDiMcEnabledFlag} \ || \ \text{IvResPredEnabledFlag} \ || \ \text{VspMcEnabledFlag} \ || \ \text{DbbpEnabledFlag} \quad (\text{I-31})$$

When `TexMcEnabledFlag` is equal to 1, or `CqtCuPartPredEnabledFlag` is equal to 1, or `IntraContourEnabledFlag` is equal to 1, let `TexturePic` be the picture in the current access unit with `nuh_layer_id` equal to `ViewCompLayerId[ViewIdx][0]`.

num_inter_layer_ref_pics_minus1 plus 1 specifies the number of pictures that may be used in decoding of the current picture for inter-layer prediction. The length of the `num_inter_layer_ref_pics_minus1` syntax element is $\text{Ceil}(\text{Log2}(\text{NumRefListLayers}[\text{nuh_layer_id}]))$ bits. The value of `num_inter_layer_ref_pics_minus1` shall be in the range of 0 to `NumRefListLayers[nuh_layer_id] - 1`, inclusive.

The variables `numRefLayerPics` and `refLayerPicIdx[j]` are derived as follows:

```
for( i = 0, j = 0; i < NumRefListLayers[ nuh_layer_id ]; i++ ) {
    refLayerIdx = LayerIdxInVps[ IdRefListLayer[ nuh_layer_id ][ i ] ]
    if( sub_layers_vps_max_minus1[ refLayerIdx ] >= TemporalId && ( TemporalId == 0 ||
        max_tid_il_ref_pics_plus1[ refLayerIdx ][ LayerIdxInVps[ nuh_layer_id ] ] > TemporalId ) )
        refLayerPicIdx[ j++ ] = i
    }
numRefLayerPics = j
```

The variable `NumActiveRefLayerPics` is derived as follows:

```
if( nuh_layer_id == 0 || numRefLayerPics == 0 )
    NumActiveRefLayerPics = 0
else if( default_ref_layers_active_flag )
    NumActiveRefLayerPics = numRefLayerPics
else if( !inter_layer_pred_enabled_flag )
    NumActiveRefLayerPics = 0
else if( max_one_active_ref_layer_flag || NumRefListLayers[ nuh_layer_id ] == 1 )
    NumActiveRefLayerPics = 1
else
    NumActiveRefLayerPics = num_inter_layer_ref_pics_minus1 + 1
```

All slices of a coded picture shall have the same value of `NumActiveRefLayerPics`.

inter_layer_pred_layer_idc[i] specifies the variable, **RefPicLayerId[i]**, representing the **nuh_layer_id** of the *i*-th picture that may be used by the current picture for inter-layer prediction. The length of the **inter_layer_pred_layer_idc[i]** syntax element is $\text{Ceil}(\text{Log2}(\text{NumRefListLayers}[\text{nuh_layer_id}]))$ bits. The value of **inter_layer_pred_layer_idc[i]** shall be in the range of 0 to $\text{NumRefListLayers}[\text{nuh_layer_id}] - 1$, inclusive. When *i* is greater than 0, **inter_layer_pred_layer_idc[i]** shall be greater than **inter_layer_pred_layer_idc[i - 1]**. When not present, the value of **inter_layer_pred_layer_idc[i]** is inferred to be equal to **refLayerPicIdc[i]**.

The variables **RefPicLayerId[i]** for all values of *i* in the range of 0 to $\text{NumActiveRefLayerPics} - 1$, inclusive, are derived as follows:

$$\begin{aligned} &\text{for}(i = 0, j = 0; i < \text{NumActiveRefLayerPics}; i++) \\ &\quad \text{RefPicLayerId}[i] = \text{IdRefListLayer}[\text{nuh_layer_id}][\text{inter_layer_pred_layer_idc}[i]] \end{aligned} \quad (\text{I-34})$$

The variable **NumExtraMergeCand** is derived as follows:

$$\text{NumExtraMergeCand} = \text{IvDiMcEnabledFlag} \mid \mid \text{TexMcEnabledFlag} \mid \mid \text{VspMcEnabledFlag} \quad (\text{I-35})$$

five_minus_max_num_merge_cand specifies the maximum number of merging motion vector prediction (MVP) candidates supported in the slice subtracted from $(5 + \text{NumExtraMergeCand})$.

The maximum number of merging MVP candidates, **MaxNumMergeCand** is derived as follows:

$$\text{MaxNumMergeCand} = 5 + \text{NumExtraMergeCand} - \text{five_minus_max_num_merge_cand} \quad (\text{I-36})$$

The value of **MaxNumMergeCand** shall be in the range of 1 to $(5 + \text{NumExtraMergeCand})$, inclusive.

slice_ic_enabled_flag equal to 1 specifies that the **illu_comp_flag[x0][y0]** syntax element may be present in coding units of the current slice. **slice_ic_enabled_flag** equal to 0 specifies that the **illu_comp_flag[x0][y0]** syntax element is not present in coding units of the current slice. When not present, the value of **slice_ic_enabled_flag** is inferred to be equal to 0.

slice_ic_disabled_merge_zero_idx_flag equal to 1 specifies that the **illu_comp_flag[x0][y0]** syntax element is not present in coding units of the current slice when **merge_flag[x0][y0]** is equal to 1 and **merge_idx[x0][y0]** is equal to 0. **slice_ic_disabled_merge_zero_idx_flag** equal to 0 specifies that **illu_comp_flag[x0][y0]** syntax element may be present in coding units of the current slice when **merge_flag[x0][y0]** is equal to 1 and **merge_idx[x0][y0]** is equal to 0. When not present, the value of **slice_ic_disabled_merge_zero_idx_flag** is inferred to be equal to 0.

cp_scale[j], **cp_off[j]**, **cp_inv_scale_plus_scale[j]**, and **cp_inv_off_plus_off[j]** specify parameters for the derivation of a horizontal component of a disparity vector from a depth value. When not present and **CpPresentFlag[ViewIdx][j]** is equal to 1, the values of **cp_scale[j]**, **cp_off[j]**, **cp_inv_scale_plus_scale[j]**, and **cp_inv_off_plus_off[j]** are inferred to be equal to **vps_cp_scale[ViewIdx][j]**, **vps_cp_off[ViewIdx][j]**, **vps_cp_inv_scale_plus_scale[ViewIdx][j]**, and **vps_cp_inv_off_plus_off[ViewIdx][j]**, respectively. It is a requirement of bitstream conformance, that the values of **cp_scale[j]**, **cp_off[j]**, **cp_inv_scale_plus_scale[j]**, and **cp_inv_off_plus_off[j]** in a slice header having a **ViewIdx** equal to **viewIdxA** and the values of **cp_scale[j]**, **cp_off[j]**, **cp_inv_scale_plus_scale[j]**, and **cp_inv_off_plus_off[j]** in a slice header having a **ViewIdx** equal to **viewIdxB** shall be the same, when **viewIdxA** is equal to **viewIdxB**.

The variable **DepthToDisparityB[j][d]** specifying the horizontal component of a disparity vector between the current view and the view with **ViewIdx** equal *j* corresponding to the depth value *d* in the view with **ViewIdx** equal to *j* and the variable **DepthToDisparityF[j][d]** specifying the horizontal component of a disparity vector between the view with **ViewIdx** equal *j* and the current view corresponding to the depth value *d* in the current view are derived as follows:

- The variable **log2Div** is set equal to $(\text{BitDepth}_Y - 1 + \text{cp_precision})$.
- For *d* in range of 0 to $((1 \ll \text{BitDepth}_Y) - 1)$, inclusive, the following applies:
 - For *m* in the range of 0 to $(\text{num_cp}[\text{ViewIdx}] - 1)$, inclusive, the following applies:

$$j = \text{cp_ref_voi}[\text{ViewIdx}][m] \quad (\text{I-37})$$

$$\text{offset} = (\text{cp_off}[j] \ll \text{BitDepth}_Y) + ((1 \ll \text{log2Div}) \gg 1) \quad (\text{I-38})$$

$$\text{scale} = \text{cp_scale}[j] \quad (\text{I-39})$$

$$\text{DepthToDisparityB}[j][d] = (\text{scale} * d + \text{offset}) \gg \text{log2Div} \quad (\text{I-40})$$

$$\text{invOffset} = ((\text{cp_inv_off_plus_off}[j] - \text{cp_off}[j]) \ll \text{BitDepth}_Y) + ((1 \ll \text{log2Div}) \gg 1) \quad (\text{I-41})$$

$$\text{invScale} = \text{cp_inv_scale_plus_scale}[j] - \text{cp_scale}[j] \quad (\text{I-42})$$

$$\text{DepthToDisparityF}[j][d] = (\text{invScale} * d + \text{invOffset}) \gg \text{log2Div} \quad (\text{I-43})$$

I.7.4.7.2 Reference picture list modification semantics

The specifications in clause F.7.4.7.2 apply.

I.7.4.7.3 Weighted prediction parameters semantics

The specifications in clause F.7.4.7.3 apply.

I.7.4.8 Short-term reference picture set semantics

The specifications in clause F.7.4.8 apply.

I.7.4.9 Slice segment data semantics

I.7.4.9.1 General slice segment data semantics

The specifications in clause F.7.4.9.1 apply.

I.7.4.9.2 Coding tree unit semantics

The specifications in clause F.7.4.9.2 apply.

I.7.4.9.3 Sample adaptive offset semantics

The specifications in clause F.7.4.9.3 apply.

I.7.4.9.4 Coding quadtree semantics

The specifications in clause F.7.4.9.4 apply with the following modifications:

The variable `predSplitCuFlag` specifying whether the `split_cu_flag[x0][y0]` syntax element is inter-component predicted is derived as follows:

- If `CqtCuPartPredEnabledFlag` is equal to 1, the following applies:
 - Let `colTextCu` be the coding unit containing the luma coding block covering the luma location (`x0`, `y0`) in the picture `TexturePic`.
 - The variable `log2TextCbSize` is set equal to `log2CbSize` of the coding unit `colTextCu`.
 - The variable `predSplitCuFlag` is set equal to (`log2CbSize <= log2TextCbSize`).
- Otherwise (`CqtCuPartPredEnabledFlag` is equal to 0), `predSplitCuFlag` is set equal to 0.

`split_cu_flag[x0][y0]` specifies whether a coding unit is split into coding units with half horizontal and vertical size. The array indices `x0`, `y0` specify the location (`x0`, `y0`) of the top-left luma sample of the considered coding block relative to the top-left luma sample of the picture.

When `split_cu_flag[x0][y0]` is not present, the following applies:

- If `log2CbSize` is greater than `MinCbLog2SizeY` and `predSplitCuFlag` is equal to 0, the value of `split_cu_flag[x0][y0]` is inferred to be equal to 1.
- Otherwise (`log2CbSize` is equal to `MinCbLog2SizeY` or `predSplitCuFlag` is equal to 1), the value of `split_cu_flag[x0][y0]` is inferred to be equal to 0.

I.7.4.9.5 Coding unit semantics

The specifications in clause F.7.4.9.5 apply with the following modifications and additions:

`cu_skip_flag[x0][y0]` equal to 1 specifies that for the current coding unit, when decoding a P or B slice, no more syntax elements except the merging candidate index `merge_idx[x0][y0]`, the `iv_res_pred_weight_idx[x0][y0]` syntax element, and the `illu_comp_flag[x0][y0]` syntax element may be parsed after `cu_skip_flag[x0][y0]`. `cu_skip_flag[x0][y0]` equal to 0 specifies that the coding unit is not skipped. The array indices `x0`, `y0` specify the location (`x0`, `y0`) of the top-left luma sample of the considered coding block relative to the top-left luma sample of the picture.

When `cu_skip_flag[x0][y0]` is not present, it is inferred to be equal to 0.

`skip_intra_flag[x0][y0]` equal to 1 specifies that for the current coding unit no more syntax elements except `skip_intra_mode_idx[x0][y0]` are parsed after `skip_intra_flag[x0][y0]`. `skip_intra_flag[x0][y0]` equal to 0 specifies that more syntax elements may be parsed after `skip_intra_flag[x0][y0]`. When not present, the value of `skip_intra_flag[x0][y0]` is inferred to be equal to 0.

pred_mode_flag equal to 0 specifies that the current coding unit is coded in inter prediction mode. **pred_mode_flag** equal to 1 specifies that the current coding unit is coded in intra prediction mode. The variable $\text{CuPredMode}[x][y]$ is derived as follows for $x = x0..x0 + nCbS - 1$ and $y = y0..y0 + nCbS - 1$:

- If **pred_mode_flag** is equal to 0, $\text{CuPredMode}[x][y]$ is set equal to **MODE_INTER**.
- Otherwise (**pred_mode_flag** is equal to 1), $\text{CuPredMode}[x][y]$ is set equal to **MODE_INTRA**.

When **pred_mode_flag** is not present, the variable $\text{CuPredMode}[x][y]$ is derived as follows for $x = x0..x0 + nCbS - 1$ and $y = y0..y0 + nCbS - 1$:

- If **slice_type** is equal to I or **skip_intra_flag**[$x0][y0]$ is equal to 1, $\text{CuPredMode}[x][y]$ is inferred to be equal to **MODE_INTRA**.
- Otherwise (**slice_type** is equal to P or B and **skip_intra_flag**[$x0][y0]$ is equal to 0), when **cu_skip_flag**[$x0][y0]$ is equal to 1, $\text{CuPredMode}[x][y]$ is inferred to be equal to **MODE_SKIP**.

The variables **predPartModeFlag** and **partPredIdc** are derived as follows:

- If **CqtCuPartPredEnabledFlag** is equal to 1, the following applies:
 - Let **colTextCu** be the coding unit containing the luma coding block covering the luma location ($x0, y0$) in the picture **TexturePic**.
 - The variables **log2TextCbSize** and **partTextMode** are set equal to **log2CbSize** and **PartMode**, respectively, of the coding unit **colTextCu**.
 - The variable **predPartModeFlag** is derived as follows:

$$\text{predPartModeFlag} = \text{log2TextCbSize} == \text{log2CbSize} \ \&\& \ \text{partTextMode} == \text{PART_2Nx2N} \quad (\text{I-44})$$
 - The variable **partPredIdc** is derived as follows:
 - If one or more of the following conditions are true, **partPredIdc** is set equal to 0:
 - **log2TextCbSize** is not equal to **log2CbSize**.
 - **partTextMode** is equal to **PART_2Nx2N** or **PART_NxN**.
 - Otherwise, if **partTextMode** is equal to **PART_2NxN**, **PART_2NxN_U**, or **PART_2NxN_L**, **partPredIdc** is set equal to 1.
 - Otherwise, **partPredIdc** is set equal to 2.
- Otherwise (**CqtCuPartPredEnabledFlag** is equal to 0), **predPartModeFlag** and **partPredIdc** are set equal to 0.

part_mode specifies partitioning mode of the current coding unit. The semantics of **part_mode** depend on $\text{CuPredMode}[x0][y0]$. The variables **PartMode** and **IntraSplitFlag** are derived from the value of **part_mode** and **partPredIdc** as defined in Table I.1

Table I.1 – Name association to prediction mode and partitioning type

CuPredMode [$x0$][$y0$]	part_mode	partPredIdc	IntraSplitFlag	PartMode
------------------------------------	------------------	--------------------	-----------------------	-----------------

MODE_INTRA	0	0	0	PART_2Nx2N
	1	0	1	PART_NxN
MODE_INTER	0	0	0	PART_2Nx2N
	1	0	0	PART_2NxN
	2	0	0	PART_Nx2N
	3	0	0	PART_NxN
	4	0	0	PART_2NxN
	5	0	0	PART_2NxN
	6	0	0	PART_nLx2N
	7	0	0	PART_nRx2N
	0	1	0	PART_2Nx2N
	1	1	0	PART_2NxN
	2	1	0	PART_2NxN
	3	1	0	PART_2NxN
	0	2	0	PART_2Nx2N
	1	2	0	PART_Nx2N
	2	2	0	PART_nLx2N
	3	2	0	PART_nRx2N

The value of part_mode is restricted as follows:

- If CuPredMode[x0][y0] is equal to MODE_INTRA, part_mode shall be equal to 0 or 1.
- Otherwise (CuPredMode[x0][y0] is equal to MODE_INTER), the following applies:
 - If partPredIdc is equal to 0, the following applies:
 - If log2CbSize is greater than MinCbLog2SizeY and amp_enabled_flag is equal to 1, part_mode shall be in the range of 0 to 2, inclusive, or in the range of 4 to 7, inclusive.
 - Otherwise, if log2CbSize is greater than MinCbLog2SizeY and amp_enabled_flag is equal to 0, or log2CbSize is equal to 3, part_mode shall be in the range of 0 to 2, inclusive.
 - Otherwise (log2CbSize is greater than 3 and less than or equal to MinCbLog2SizeY), the value of part_mode shall be in the range of 0 to 3, inclusive.
 - Otherwise (partPredIdc is not equal to 0), the following applies:
 - If log2CbSize is greater than MinCbLog2SizeY and amp_enabled_flag is equal to 1, part_mode shall be in the range of 0 to 3, inclusive.
 - Otherwise (log2CbSize is equal to MinCbLog2SizeY or amp_enabled_flag is equal to 0), part_mode shall be in the range of 0 to 1, inclusive.

When part_mode is not present, the variables PartMode and IntraSplitFlag are derived as follows:

- PartMode is set equal to PART_2Nx2N.
- IntraSplitFlag is set equal to 0.

rqt_root_cbf equal to 1 specifies that the transform_tree() syntax structure is present for the current coding unit. **rqt_root_cbf** equal to 0 specifies that the transform_tree() syntax structure is not present for the current coding unit. When not present, the value of rqt_root_cbf is inferred to be equal to !DcOnlyFlag[x0][y0].

I.7.4.9.5.1 Intra mode extension semantics

no_dim_flag[x0][y0] equal to 1 specifies that the intra modes INTRA_WEDGE or INTRA_CONTOUR are not used for the current prediction unit. **no_dim_flag**[x0][y0] equal to 0 specifies that the intra mode INTRA_WEDGE or INTRA_CONTOUR is used for the current prediction unit. When not present, the value of no_dim_flag[x0][y0] is inferred to be equal to 1. When log2CbSize is greater than MaxTbLog2SizeY and DcOnlyFlag[x0][y0] is equal to 0, the value of no_dim_flag[x0][y0] shall be equal to 1.

For $x = x0..x0 + (1 \ll \log2PbSize) - 1$, $y = y0..y0 + (1 \ll \log2PbSize) - 1$, the variable DimFlag[x][y] is derived as follows:

$$\text{DimFlag}[x][y] = \text{!no_dim_flag}[x0][y0] \quad (\text{I-45})$$

depth_intra_mode_idx_flag[x0][y0] equal to 0, when **DimFlag**[x0][y0] is equal to 1, specifies that the intra mode INTRA_WEDGE is used for the current prediction unit. **depth_intra_mode_idx_flag**[x0][y0] equal to 1, when **DimFlag**[x0][y0] is equal to 1, specifies that the intra mode INTRA_CONTOUR is used for the current prediction unit. When not present, the value of **depth_intra_mode_idx_flag**[x0][y0] is inferred to be equal to (**!IntraDcOnlyWedgeEnabledFlag** || **IntraContourEnabledFlag**). When **DimFlag**[x0][y0] is equal to 1 and **nal_unit_type** is equal to BLA_W_LP, BLA_W_RADL, BLA_N_LP, IDR_W_RADL or IDR_N_LP, it is a requirement of bitstream conformance that **depth_intra_mode_idx_flag**[x0][y0] is equal to 0.

wedge_full_tab_idx[x0][y0] specifies the index of the partition pattern in the list **WedgePatternTable**[log2PbSize] when the intra mode INTRA_WEDGE is used for the current prediction unit.

1.7.4.9.5.2 Coding unit extension semantics

skip_intra_mode_idx[x0][y0] equal to 0, when **skip_intra_flag**[x0][y0] is equal to 1, specifies that the intra prediction mode INTRA_ANGULAR26 is used for the current prediction unit. **skip_intra_mode_idx**[x0][y0] equal to 1, when **skip_intra_flag**[x0][y0] is equal to 1, specifies that the intra prediction mode INTRA_ANGULAR10 is used for the current prediction unit. **skip_intra_mode_idx**[x0][y0] equal to 2 or 3, when **skip_intra_flag**[x0][y0] is equal to 1, specifies that the intra prediction mode INTRA_SINGLE is used for the current prediction unit.

dbbp_flag[x0][y0] equal to 1 specifies that the decoding process for inter sample prediction for depth predicted sub-block partitions is used for the current coding unit. **dbbp_flag**[x0][y0] equal to 0 specifies that the decoding process for inter sample prediction for depth predicted sub-block partitions is not used for the current coding unit. When not present, the value of **dbbp_flag**[x0][y0] is inferred to be equal to 0.

For $x = x0..x0 + (1 \ll \log2CbSize) - 1$, $y = y0..y0 + (1 \ll \log2CbSize) - 1$, the variable **DbbpFlag**[x][y] is derived as follows:

$$\text{DbbpFlag}[x][y] = \text{dbbp_flag}[x0][y0] \quad (\text{I-46})$$

dc_only_flag[x0][y0] equal to 1 specifies that the **transform_tree()** syntax structure is not present for the current coding unit and that the **depth_dcs()** syntax structure is present for the current coding unit. **dc_only_flag**[x0][y0] equal to 0 specifies the **transform_tree()** syntax structure may be present for the current coding unit and that the **depth_dcs()** syntax structure may be present for the current coding unit. When not present, the value of **dc_only_flag**[x0][y0] is inferred to be equal to 0. It is a requirement of bitstream conformance, that when **pcm_flag**[x0][y0] is equal to 1, the value of **dc_only_flag**[x0][y0] shall be equal to 0.

For $x = x0..x0 + (1 \ll \log2CbSize) - 1$, $y = y0..y0 + (1 \ll \log2CbSize) - 1$, the variable **DcOnlyFlag**[x][y] is derived as follows:

$$\text{DcOnlyFlag}[x][y] = \text{dc_only_flag}[x0][y0] \quad (\text{I-47})$$

iv_res_pred_weight_idx[x0][y0] not equal to 0 specifies that the bilinear sample interpolation and residual prediction process is used for the current coding unit and the index of the weighting factor used in the bilinear sample interpolation and residual prediction process. **iv_res_pred_weight_idx**[x0][y0] equal to 0 specifies that the bilinear sample interpolation and residual prediction process is not used for the current coding unit. When not present, the value of **iv_res_pred_weight_idx**[x0][y0] is inferred to be equal to 0.

When **CuPredMode**[x0][y0] is not equal to **MODE_INTRA**, the variable **icCuEnableFlag** is derived as follows:

- If **merge_flag**[x0][y0] is equal to 1, the following applies:

$$\text{icCuEnableFlag} = (\text{merge_idx}[x0][y0] \neq 0) \mid \mid \text{!slice_ic_disabled_merge_zero_idx_flag} \quad (\text{I-48})$$

- Otherwise (**merge_flag**[x0][y0] is equal to 0), the following applies:

- For X in the range of 0 to 1, inclusive, the variable **refViewIdxLX** is set equal to **ViewIdx(RefPicListX[ref_idx_IX[x0][y0]])**.
- The flag **icCuEnableFlag** is derived as follows:

$$\text{icCuEnableFlag} = (\text{inter_pred_idx}[x0][y0] \neq \text{Pred_L0} \ \&\& \ \text{refViewIdxL1} \neq \text{ViewIdx}) \mid \mid (\text{inter_pred_idx}[x0][y0] \neq \text{Pred_L1} \ \&\& \ \text{refViewIdxL0} \neq \text{ViewIdx}) \quad (\text{I-49})$$

illu_comp_flag[x0][y0] equal to 1 specifies that the illumination compensated sample prediction process is used for the current coding unit. **illu_comp_flag**[x0][y0] equal to 0 specifies that the illumination compensated sample prediction process is not used for the current coding unit. When not present, the value of **illu_comp_flag**[x0][y0] is inferred to be equal to 0.

For $x = x0..x0 + (1 \ll \log2CbSize) - 1$, $y = y0..y0 + (1 \ll \log2CbSize) - 1$, the variable **IlluCompFlag**[x][y] is

derived as follows:

$$\text{IlluCompFlag}[x][y] = \text{illu_comp_flag}[x0][y0] \quad (\text{I-50})$$

I.7.4.9.5.3 Depth DCs semantics

depth_dc_present_flag[$x0+k$][$y0+j$] equal to 1 specifies that the **depth_dc_abs**[$x0+k$][$y0+j$][i] syntax element is present and that the **depth_dc_sign_flag**[$x0+k$][$y0+j$][i] syntax element may be present. **depth_dc_present_flag**[$x0+k$][$y0+j$] equal to 0 specifies that the **depth_dc_abs**[$x0+k$][$y0+j$][i] and **depth_dc_sign_flag**[$x0+k$][$y0+j$][i] syntax elements are not present. When not present, the value of **depth_dc_present_flag**[$x0+k$][$y0+j$] is inferred to be equal to 1.

depth_dc_abs[$x0+k$][$y0+j$][i] and **depth_dc_sign_flag**[$x0+k$][$y0+j$][i] are used to derive **DcOffset**[$x0+k$][$y0+j$][i]. When not present, the values of **depth_dc_abs**[$x0+k$][$y0+j$][i] and **depth_dc_sign_flag**[$x0+k$][$y0+j$][i] are inferred to be equal to 0. The variable **DcOffset**[$x0+k$][$y0+j$][i] is derived as follows:

$$\text{DcOffset}[x0+k][y0+j][i] = (1 - 2 * \text{depth_dc_sign_flag}[x0+k][y0+j][i]) * (\text{depth_dc_abs}[x0+k][y0+j][i] - \text{dcNumSeg} + 2) \quad (\text{I-51})$$

I.7.4.9.6 Prediction unit semantics

The specifications in clause F.7.4.9.6 apply with the following addition at the end of the specification of semantics of **inter_pred_idc**[$x0$][$y0$]:

It is a requirement of bitstream conformance that, when **DbbpFlag**[$x0$][$y0$] is equal to 1, **inter_pred_idc**[$x0$][$y0$] shall not be equal to **PRED_BI**.

I.7.4.9.7 PCM sample semantics

The specifications in clause F.7.4.9.7 apply.

I.7.4.9.8 Transform tree semantics

The specifications in clause F.7.4.9.8 apply with the following additions at the end of the specification of **split_transform_flag**[$x0$][$y0$][**trafoDepth**]:

When **DimFlag**[$x0$][$y0$] is equal to 1 and **PartMode** is equal to **PART_2Nx2N**, the value of **split_transform_flag**[$x0$][$y0$][0] shall be equal to 0.

When **DimFlag**[$x0$][$y0$] is equal to 1 and **PartMode** is equal to **PART_NxN**, the value of **split_transform_flag**[$x0$][$y0$][1] shall be equal to 0.

I.7.4.9.9 Motion vector difference coding semantics

The specifications in clause F.7.4.9.9 apply.

I.7.4.9.10 Transform unit semantics

The specifications in clause F.7.4.9.10 apply.

I.7.4.9.11 Residual coding semantics

The specifications in clause F.7.4.9.11 apply.

I.7.4.9.12 Cross-component prediction semantics

The specifications in clause F.7.4.9.12 apply.

I.7.4.9.13 Palette mode semantics

The specifications in clause F.7.4.9.13 apply.

I.7.4.9.14 Delta QP semantics

The specifications in clause F.7.4.9.14 apply.

I.7.4.9.15 Chroma QP offset semantics

The specifications in clause F.7.4.9.15 apply.

I.8 Decoding process

I.8.1 General decoding process

I.8.1.1 General

The specifications in clause F.8.1.1 apply.

I.8.1.2 Decoding process for a coded picture with nuh_layer_id greater than 0

The decoding process for the current picture CurrPic is as follows:

1. The decoding of NAL units is specified in clause I.8.2.
2. The processes in clauses G.8.1.3, F.8.3.4 and I.8.3.1 to I.8.3.5 specify the following decoding processes using syntax elements in the slice segment layer and above:
 - Prior to decoding the first slice of the current picture, clause G.8.1.3 is invoked.
 - At the beginning of the decoding process for each P or B slice, the decoding process for reference picture lists construction specified in clause F.8.3.4 is invoked for derivation of reference picture list 0 (RefPicList0), and when decoding a B slice, reference picture list 1 (RefPicList1).
 - When DisparityDerivationFlag is equal to 1 and DepthFlag is equal to 0, the derivation process for the candidate picture list for disparity vector derivation in clause I.8.3.1 is invoked at the beginning of the decoding process for each P or B slice.
 - The variable DefaultRefViewIdx is set equal to –1 and the variable DispAvailFlag is set equal to 0.
 - When DisparityDerivationFlag is equal to 1, the derivation process for the default reference view order index for disparity derivation as specified in clause I.8.3.2 is invoked at the beginning of the decoding process for each P or B slice.
 - When DltFlag[nuh_layer_id] is equal to 1, the derivation process for a depth look-up table in clause I.8.3.3 is invoked at the beginning of the decoding process of the first slice segment of a coded picture.
 - At the beginning of the decoding process for each P or B slice, the derivation process for the alternative target reference index for temporal motion vector prediction in merge mode as specified in clause I.8.3.4 is invoked.
 - When IvResPredEnabledFlag is equal to 1, the derivation process for the target reference index for residual prediction as specified in clause I.8.3.5 is invoked at the beginning of the decoding process for each P or B slice.
3. The processes in clauses I.8.4, I.8.5, I.8.6, and I.8.7, specify decoding processes using syntax elements in all syntax structure layers. It is a requirement of bitstream conformance that the coded slices of the picture shall contain slice segment data for every CTU of the picture, such that the division of the picture into slices, the division of the slices into slice segments, and the division of the slice segments into CTUs each form a partitioning of the picture.

I.8.2 NAL unit decoding process

The specifications in clause G.8.2 apply.

I.8.3 Slice decoding process

I.8.3.1 Derivation process for the candidate picture list for disparity vector derivation

The function tempId(picA) is specified as follows:

$$\text{tempId}(\text{picA}) = \text{TemporalId of picA} \quad (\text{I-52})$$

The variable NumDdvCandPics is set equal to 0 and when slice_temporal_mvp_enabled_flag is equal to 1, the list DdvCandPicList is constructed as follows:

1. The variable X is set equal to (1 – collocated_from_l0_flag), the variable DdvCandPicList[0] is set equal to RefPicListX[collocated_ref_idx], and NumDdvCandPics is set equal to 1.
2. The variables NumDdvCandPics, DdvCandPicList[1], and minTempIdRefs are derived as follows:

```
minTempIdRefs = 7
for( k = 0; k <= ( slice_type == B ? 1 : 0 ); k++ ) {
    X = k ? collocated_from_l0_flag : ( 1 – collocated_from_l0_flag )
    for( i = 0; i <= num_ref_idx_lX_active_minus1; i++ )
```

```

    if( ViewIdx == ViewIdx( RefPicListX[ i ] )
        && NumDdvCandPics != 2
        && ( X == collocated_from_l0_flag || i != collocated_ref_idx ) )
    if( RefPicListX[ i ] is an IRAP picture )
        DdvCandPicList[ NumDdvCandPics++ ] = RefPicListX[ i ]
    else
        minTempIdRefs = Min( minTempIdRefs, tempId( RefPicListX[ i ] ) )
}

```

(I-53)

3. When NumDdvCandPics is equal to 1, the following applies:

```

minPocDiff = 255
for( k = 0; k <= ( slice_type == B ? 1 : 0 ); k++ ) {
    X = k ? collocated_from_l0_flag : ( 1 - collocated_from_l0_flag )
    for( i = 0; i <= num_ref_idx_lX_active_minus1; i++ )
        if( ViewIdx == ViewIdx( RefPicListX[ i ] )
            && ( X == collocated_from_l0_flag || i != collocated_ref_idx )
            && tempId( RefPicListX[ i ] ) == minTempIdRefs
            && Abs( DiffPicOrderCnt( CurrPic, RefPicListX[ i ] ) ) < minPocDiff ) {
                minPocDiff = Abs( DiffPicOrderCnt( CurrPic, RefPicListX[ i ] ) )
                Z = X
                candIdx = i
        }
    }
if( minPocDiff < 255 )
    DdvCandPicList[ NumDdvCandPics++ ] = RefPicListZ[ candIdx ]

```

(I-54)

I.8.3.2 Derivation process for the default reference view order index for disparity derivation

This process is invoked when the current slice is a P or B slice.

The following applies for candViewIdx in the range of 0 to (ViewIdx - 1), inclusive:

- The following applies for X in the range of 0 to (slice_type == B) ? 1 : 0, inclusive:
 - The following applies for i in the range of 0 to num_ref_idx_lX_active_minus1, inclusive:
 - When all of the following conditions are true, DefaultRefViewIdx is set equal to candViewIdx and DispAvailFlag is set equal to 1.
 - DispAvailFlag is equal to 0.
 - ViewIdx(RefPicListX[i]) is equal to candViewIdx.
 - DiffPicOrderCnt(CurrPic, RefPicListX[i]) is equal to 0.

When DepthFlag is equal to 1, DisparityDerivationFlag is equal to 1, and DispAvailFlag is equal to 1, it is a requirement of bitstream conformance that CpPresentFlag[ViewIdx][DefaultRefViewIdx] shall be equal to 1.

I.8.3.3 Derivation process for a depth look-up table

For i in the range of 0 to (1 << BitDepth_Y) - 1, inclusive, the list DltIdxToVal[i] specifying the depth value corresponding to the i-th index in the depth look-up table is derived as follows:

$$\text{DltIdxToVal}[i] = (i < \text{NumValDlt}[\text{nuh_layer_id}]) ? \text{DltVal}[\text{nuh_layer_id}][i] : 0 \quad (\text{I-55})$$

The list DltValToIdx[d] specifying the index in the depth look-up table corresponding to the depth value d is derived as follows:

```

for( d = 0; d < ( 1 << BitDepthY ); d++ ) {
    idxLower = 0
    foundFlag = 0
    for( iL = 1; iL < NumValDlt[ nuh_layer_id ]; iL++ )
        if( !foundFlag && DltIdxToVal[ iL ] > d ) {
            idxLower = iL - 1
            foundFlag = 1
        }
    idxUpper = foundFlag ? ( idxLower + 1 ) : ( NumValDlt[ nuh_layer_id ] - 1 )
    if( Abs( d - DltIdxToVal[ idxLower ] ) < Abs( d - DltIdxToVal[ idxUpper ] ) )
        DltValToIdx[ d ] = idxLower
}

```

(I-56)

```

else
    DltValToIdx[ d ] = idxUpper
}

```

I.8.3.4 Derivation process for the alternative target reference index for temporal motion vector prediction in merge mode

This process is invoked when the current slice is a P or B slice.

The variables AltRefIdxL0 and AltRefIdxL1 are set equal to -1 and the following applies for X in the range of 0 to (slice_type == B) ? 1 : 0, inclusive:

```

zeroIdxLtFlag = RefPicListX[ 0 ] is a short-term reference picture ? 0 : 1
for( i = 1; i <= num_ref_idx_LX_active_minus1 && AltRefIdxLX == -1; i++ )
    if( ( zeroIdxLtFlag && RefPicListX[ i ] is a short-term reference picture ) ||
        ( !zeroIdxLtFlag && RefPicListX[ i ] is a long-term reference picture ) )
        AltRefIdxLX = i

```

(I-57)

I.8.3.5 Derivation process for the target reference index for residual prediction

This process is invoked when the current slice is a P or B slice.

For X in the range of 0 to 1, inclusive, the following applies:

- The variable RpRefIdxLX is set equal to -1 and the variable RpRefPicAvailFlagLX is set equal to 0.
- For i in the range of 0 to NumViews - 1, inclusive, the following applies:
 - The variable RefRpRefAvailFlagLX[ViewOidxList[i]] is set equal to 0.

For X in the range of 0 to (slice_type == B) ? 1 : 0, inclusive, the following applies:

- The variable minPocDiff is set equal to $2^{15} - 1$.
- For i in the range of 0 to num_ref_idx_LX_active_minus1, inclusive, the following applies:
 - The variable pocDiff is set equal to Abs(DiffPicOrderCnt(CurrPic, RefPicListX[i])).
 - When pocDiff is not equal to 0 and pocDiff is less than minPocDiff, the following applies:

minPocDiff = pocDiff (I-58)

RpRefIdxLX = i (I-59)

RpRefPicAvailFlagLX = 1 (I-60)

- When DispAvailFlag is equal to 1 and RpRefPicAvailFlagLX is equal to 1, the following applies for i in the range of 0 to NumActiveRefLayerPics - 1, inclusive:
 - Let picV the picture in the current AU with nuh_layer_id equal to RefPicLayerId[i].
 - When there is a picture picA in one of the reference picture sets RefPicSetLtCurr, RefPicSetStCurrBefore, and RefPicSetStCurrAfter of picV with DiffPicOrderCnt(picA, RefPicListX[RpRefIdxLX]) equal to 0, RefRpRefAvailFlagLX[ViewIdx(RefPicLayerId[i])] is set equal to 1.

The variable RpRefPicAvailFlag is derived as follows:

RpRefPicAvailFlag = (RpRefPicAvailFlagL0 || RpRefPicAvailFlagL1) && DispAvailFlag (I-61)

When RpRefPicAvailFlag is equal to 1 and RefRpRefAvailFlagL0[ViewOidxList[i]] is equal to 1 for any i in the range of 0 to NumViews - 1, inclusive, it is a requirement of bitstream conformance that PicOrderCnt(RefPicList0[RpRefIdxL0]) shall be the same for all slices of a coded picture.

When RpRefPicAvailFlag is equal to 1 and RefRpRefAvailFlagL1[ViewOidxList[i]] is equal to 1 for any i in the range of 0 to NumViews - 1, inclusive, it is a requirement of bitstream conformance that PicOrderCnt(RefPicList1[RpRefIdxL1]) shall be the same for all slices of a coded picture.

I.8.4 Decoding process for coding units coded in intra prediction mode

I.8.4.1 General decoding process for coding units coded in intra prediction mode

The specifications in clause 8.4.1 apply with the following modification:

- All invocations of the process specified in clause 8.4.2 are replaced with invocations of the process specified in

clause I.8.4.2.

- All invocations of the process specified in clause 8.4.4.1 are replaced with invocations of the process specified in clause I.8.4.4.1.

I.8.4.2 Derivation process for luma intra prediction mode

Input to this process is a luma location (xPb, yPb) specifying the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture.

In this process, the luma intra prediction mode $\text{IntraPredModeY}[xPb][yPb]$ is derived.

Table I.2 specifies the value for the intra prediction mode and the associated names.

Table I.2 – Specification of intra prediction mode and associated names

Intra prediction mode	Associated name
0	INTRA_PLANAR
1	INTRA_DC
2..34	INTRA_ANGULAR2..INTRA_ANGULAR34
35	INTRA_WEDGE
36	INTRA_CONTOUR
37	INTRA_SINGLE

$\text{IntraPredModeY}[xPb][yPb]$ labelled 0..34 represents directions of predictions as illustrated in Figure 8-1.

- If $\text{skip_intra_flag}[xPb][yPb]$ is equal to 1, the following applies:
 - If $\text{skip_intra_mode_idx}[xPb][yPb]$ is equal to 0, $\text{IntraPredModeY}[xPb][yPb]$ is set equal to INTRA_ANGULAR26.
 - Otherwise, if $\text{skip_intra_mode_idx}[xPb][yPb]$ is equal to 1, $\text{IntraPredModeY}[xPb][yPb]$ is set equal to INTRA_ANGULAR10.
 - Otherwise ($\text{skip_intra_mode_idx}[xPb][yPb]$ is equal to 2 or 3), $\text{IntraPredModeY}[xPb][yPb]$ is set equal to INTRA_SINGLE.
- Otherwise, if $\text{DimFlag}[xPb][yPb]$ is equal to 1, the following applies:
 - If $\text{depth_intra_mode_idx_flag}[xPb][yPb]$ is equal to 0, $\text{IntraPredModeY}[xPb][yPb]$ is set equal to INTRA_WEDGE.
 - Otherwise ($\text{depth_intra_mode_idx_flag}[xPb][yPb]$ is equal to 1), $\text{IntraPredModeY}[xPb][yPb]$ is set equal to INTRA_CONTOUR.
- Otherwise ($\text{skip_intra_flag}[xPb][yPb]$ and $\text{DimFlag}[xPb][yPb]$ are both equal to 0), $\text{IntraPredModeY}[xPb][yPb]$ is derived by the following ordered steps:
 1. The neighbouring locations (xNbA, yNbA) and (xNbB, yNbB) are set equal to (xPb – 1, yPb) and (xPb, yPb – 1), respectively.
 2. For X being replaced by either A or B, the variables $\text{candIntraPredModeX}$ are derived as follows:
 - The availability derivation process for a block in z-scan order as specified in clause 6.4.1 is invoked with the location (xCurr, yCurr) set equal to (xPb, yPb) and the neighbouring location (xNbY, yNbY) set equal to (xNbX, yNbX) as inputs, and the output is assigned to availableX .
 - The candidate intra prediction mode $\text{candIntraPredModeX}$ is derived as follows:
 - If availableX is equal to FALSE, $\text{candIntraPredModeX}$ is set equal to INTRA_DC.
 - Otherwise, if $\text{CuPredMode}[xNbX][yNbX]$ is not equal to MODE_INTRA or $\text{pcm_flag}[xNbX][yNbX]$ is equal to 1, $\text{candIntraPredModeX}$ is set equal to INTRA_DC,
 - Otherwise, if X is equal to B and $yPb - 1$ is less than ((yPb >> CtbLog2SizeY) << CtbLog2SizeY), $\text{candIntraPredModeB}$ is set equal to INTRA_DC.
 - Otherwise, if $\text{IntraPredModeY}[xNbX][yNbX]$ is greater than 34, $\text{candIntraPredModeX}$ is set equal to INTRA_DC.

- Otherwise, $\text{candIntraPredModeX}$ is set equal to $\text{IntraPredModeY}[xNbX][yNbX]$.
3. The $\text{candModeList}[x]$ with $x = 0..2$ is derived as follows:
- If $\text{candIntraPredModeB}$ is equal to $\text{candIntraPredModeA}$, the following applies:
 - If $\text{candIntraPredModeA}$ is less than 2 (i.e., equal to INTRA_PLANAR or INTRA_DC), $\text{candModeList}[x]$ with $x = 0..2$ is derived as follows:

$$\text{candModeList}[0] = \text{INTRA_PLANAR} \quad (\text{I-62})$$

$$\text{candModeList}[1] = \text{INTRA_DC} \quad (\text{I-63})$$

$$\text{candModeList}[2] = \text{INTRA_ANGULAR26} \quad (\text{I-64})$$
 - Otherwise, $\text{candModeList}[x]$ with $x = 0..2$ is derived as follows:

$$\text{candModeList}[0] = \text{candIntraPredModeA} \quad (\text{I-65})$$

$$\text{candModeList}[1] = 2 + ((\text{candIntraPredModeA} + 29) \% 32) \quad (\text{I-66})$$

$$\text{candModeList}[2] = 2 + ((\text{candIntraPredModeA} - 2 + 1) \% 32) \quad (\text{I-67})$$
 - Otherwise ($\text{candIntraPredModeB}$ is not equal to $\text{candIntraPredModeA}$), the following applies:
 - $\text{candModeList}[0]$ and $\text{candModeList}[1]$ are derived as follows:

$$\text{candModeList}[0] = \text{candIntraPredModeA} \quad (\text{I-68})$$

$$\text{candModeList}[1] = \text{candIntraPredModeB} \quad (\text{I-69})$$
 - If neither of $\text{candModeList}[0]$ and $\text{candModeList}[1]$ is equal to INTRA_PLANAR , $\text{candModeList}[2]$ is set equal to INTRA_PLANAR ,
 - Otherwise, if neither of $\text{candModeList}[0]$ and $\text{candModeList}[1]$ is equal to INTRA_DC , $\text{candModeList}[2]$ is set equal to INTRA_DC ,
 - Otherwise, $\text{candModeList}[2]$ is set equal to INTRA_ANGULAR26 .
4. $\text{IntraPredModeY}[xPb][yPb]$ is derived by applying the following procedure:
- If $\text{prev_intra_luma_pred_flag}[xPb][yPb]$ is equal to 1, the $\text{IntraPredModeY}[xPb][yPb]$ is set equal to $\text{candModeList}[mpm_idx]$.
 - Otherwise, $\text{IntraPredModeY}[xPb][yPb]$ is derived by applying the following ordered steps:
 - 1) The array $\text{candModeList}[x]$, $x = 0..2$ is modified as the following ordered steps:
 - i. When $\text{candModeList}[0]$ is greater than $\text{candModeList}[1]$, both values are swapped as follows:

$$(\text{candModeList}[0], \text{candModeList}[1]) = \text{Swap}(\text{candModeList}[0], \text{candModeList}[1]) \quad (\text{I-70})$$
 - ii. When $\text{candModeList}[0]$ is greater than $\text{candModeList}[2]$, both values are swapped as follows:

$$(\text{candModeList}[0], \text{candModeList}[2]) = \text{Swap}(\text{candModeList}[0], \text{candModeList}[2]) \quad (\text{I-71})$$
 - iii. When $\text{candModeList}[1]$ is greater than $\text{candModeList}[2]$, both values are swapped as follows:

$$(\text{candModeList}[1], \text{candModeList}[2]) = \text{Swap}(\text{candModeList}[1], \text{candModeList}[2]) \quad (\text{I-72})$$
 - 2) $\text{IntraPredModeY}[xPb][yPb]$ is derived by the following ordered steps:
 - i. $\text{IntraPredModeY}[xPb][yPb]$ is set equal to $\text{rem_intra_luma_pred_mode}[xPb][yPb]$.
 - ii. For i equal to 0 to 2, inclusive, when $\text{IntraPredModeY}[xPb][yPb]$ is greater than or equal to $\text{candModeList}[i]$, the value of $\text{IntraPredModeY}[xPb][yPb]$ is incremented by one.

I.8.4.3 Derivation process for chroma intra prediction mode

The specifications in clause 8.4.3 apply.

I.8.4.4 Decoding process for intra blocks

I.8.4.4.1 General decoding process for intra blocks

Inputs to this process are:

- a sample location (xTb0, yTb0) specifying the top-left sample of the current transform block relative to the top-left sample of the current picture,
- a variable log2TrafoSize specifying the size of the current transform block,
- a variable trafoDepth specifying the hierarchy depth of the current block relative to the coding unit,
- a variable predModeIntra specifying the intra prediction mode,
- a variable cIdx specifying the colour component of the current block.

Output of this process is a modified reconstructed picture before deblocking filtering.

The luma sample location (xTbY, yTbY) specifying the top-left sample of the current luma transform block relative to the top-left luma sample of the current picture is derived as follows:

$$(xTbY, yTbY) = (cIdx == 0) ? (xTb0, yTb0) : (xTb0 * SubWidthC, yTb0 * SubHeightC) \quad (I-73)$$

The variable splitFlag is derived as follows:

- If DcOnlyFlag[xTbY][yTbY] is equal to 1, the following applies:

$$splitFlag = !DimFlag[xTbY][yTbY] \&\& (log2TrafoSize > MaxTbLog2SizeY) \quad (I-74)$$

- Otherwise, if skip_intra_flag[xTbY][yTbY] is equal to 1, splitFlag is set equal to 0.
- Otherwise, if cIdx is equal to 0, splitFlag is set equal to split_transform_flag[xTbY][yTbY][trafoDepth].
- Otherwise, if all of the following conditions are true, splitFlag is set equal to 1.
 - cIdx is greater than 0
 - split_transform_flag[xTbY][yTbY][trafoDepth] is equal to 1
 - log2TrafoSize is greater than 2
- Otherwise, splitFlag is set equal to 0.

Depending on the value of splitFlag, the following applies:

- If splitFlag is equal to 1, the following ordered steps apply:

1. The variables xTb1 and yTb1 are derived as follows:

- If cIdx is equal to 0 or ChromaArrayType is not equal to 2, the following applies:
 - The variable xTb1 is set equal to $xTb0 + (1 \ll (log2TrafoSize - 1))$.
 - The variable yTb1 is set equal to $yTb0 + (1 \ll (log2TrafoSize - 1))$.
- Otherwise (ChromaArrayType is equal to 2 and cIdx is greater than 0), the following applies:
 - The variable xTb1 is set equal to $xTb0 + (1 \ll (log2TrafoSize - 1))$.
 - The variable yTb1 is set equal to $yTb0 + (2 \ll (log2TrafoSize - 1))$.

2. The general decoding process for intra blocks as specified in this clause is invoked with the location (xTb0, yTb0), the variable log2TrafoSize set equal to $log2TrafoSize - 1$, the variable trafoDepth set equal to $trafoDepth + 1$, the intra prediction mode predModeIntra, and the variable cIdx as inputs, and the output is a modified reconstructed picture before deblocking filtering.
3. The general decoding process for intra blocks as specified in this clause is invoked with the location (xTb1, yTb0), the variable log2TrafoSize set equal to $log2TrafoSize - 1$, the variable trafoDepth set equal to $trafoDepth + 1$, the intra prediction mode predModeIntra, and the variable cIdx as inputs, and the output is a modified reconstructed picture before deblocking filtering.
4. The general decoding process for intra blocks as specified in this clause is invoked with the location (xTb0, yTb1), the variable log2TrafoSize set equal to $log2TrafoSize - 1$, the variable trafoDepth set equal to $trafoDepth + 1$, the intra prediction mode predModeIntra, and the variable cIdx as inputs, and the output is a modified reconstructed picture before deblocking filtering.
5. The general decoding process for intra blocks as specified in this clause is invoked with the location (xTb1, yTb1), the variable log2TrafoSize set equal to $log2TrafoSize - 1$, the variable trafoDepth set equal to $trafoDepth + 1$, the intra prediction mode predModeIntra, and the variable cIdx as inputs, and the output is a modified reconstructed picture before deblocking filtering.

- Otherwise (splitFlag is equal to 0), for the variable blkIdx proceeding over the values 0..(cIdx > 0 && ChromaArrayType == 2 ? 1 : 0), the following ordered steps apply:
 1. The variable nTbS is set equal to $1 \ll \log_2 \text{TrafoSize}$.
 2. The variable yTbOffset is set equal to $\text{blkIdx} * \text{nTbS}$.
 3. The variable yTbOffsetY is set equal to $\text{yTbOffset} * \text{SubHeightC}$.
 4. The variable residualDpcm is derived as follows:
 - If all of the following conditions are true, residualDpcm is set equal to 1.
 - implicit_rdpem_enabled_flag is equal to 1.
 - either $\text{transform_skip_flag}[\text{xTbY}][\text{yTbY} + \text{yTbOffsetY}][\text{cIdx}]$ is equal to 1, or $\text{cu_transquant_bypass_flag}$ is equal to 1.
 - either predModeIntra is equal to 10, or predModeIntra is equal to 26.
 - Otherwise, residualDpcm is set equal to 0.
 5. The general intra sample prediction process as specified in clause I.8.4.4.2.1 is invoked with the transform block location (xTb0, yTb0 + yTbOffset), the intra prediction mode predModeIntra , the transform block size nTbS, and the variable cIdx as inputs, and the output is an (nTbS)x(nTbS) array predSamples.
 6. The variable residualFlag is set equal to $!(\text{skip_intra_flag}[\text{xTb0}][\text{xTb0}] \mid \mid \text{DcOnlyFlag}[\text{xTb0}][\text{xTb0}])$ and depending on the value of residualFlag, the following applies:
 - If residualFlag is equal to 1, the following applies:
 - The scaling and transformation process as specified in clause 8.6.2 is invoked with the luma location (xTbY, yTbY + yTbOffsetY), the variable trafoDepth, the variable cIdx, and the transform size trafoSize set equal to nTbS as inputs, and the output is an (nTbS)x(nTbS) array resSamples.
 - When residualDpcm is equal to 1, the directional residual modification process for blocks using a transform bypass as specified in clause 8.6.5 is invoked with the variable mDir set equal to $\text{predModeIntra} / 26$, the variable nTbS, and the (nTbS)x(nTbS) array r set equal to the array resSamples as inputs, and the output is a modified (nTbS)x(nTbS) array resSamples.
 - When cross_component_prediction_enabled_flag is equal to 1, ChromaArrayType is equal to 3, and cIdx is not equal to 0, the residual modification process for transform blocks using cross-component prediction as specified in clause 8.6.6 is invoked with the current luma transform block location (xTbY, yTbY), the variable nTbS, the variable cIdx, the (nTbS)x(nTbS) array r_Y set equal to the corresponding luma residual sample array resSamples of the current transform block, and the (nTbS)x(nTbS) array r set equal to the array resSamples as inputs, and the output is a modified (nTbS)x(nTbS) array resSamples.
 - Otherwise (residualFlag is equal to 0), for $x, y = 0..nTbS - 1$, $\text{resSamples}[x][y]$ is set equal to 0.
 7. The picture construction process prior to in-loop filtering for a colour component as specified in clause 8.6.7 is invoked with the transform block location (xTb0, yTb0 + yTbOffset), the variables nCurrSw and nCurrSh both set equal to nTbS, the variable cIdx, the (nTbS)x(nTbS) array predSamples, and the (nTbS)x(nTbS) array resSamples as inputs.

When trafoDepth is equal to 0, $\text{DcOnlyFlag}[\text{xTb0}][\text{yTb0}]$ is equal to 1, and $\text{DimFlag}[\text{xTb0}][\text{yTb0}]$ is equal to 0, the depth DC offset assignment process as specified in clause I.8.4.4.3 is invoked with the location (xTb0, yTb0), and the transform size trafoSize set equal to nTbS as inputs.

I.8.4.4.2 Intra sample prediction

I.8.4.4.2.1 General intra sample prediction

Inputs to this process are:

- a sample location (xTbCmp, yTbCmp) specifying the top-left sample of the current transform block relative to the top-left sample of the current picture,
- a variable predModeIntra specifying the intra prediction mode,
- a variable nTbS specifying the transform block size,
- a variable cIdx specifying the colour component of the current block.

Outputs of this process are the predicted samples $\text{predSamples}[x][y]$, with $x, y = 0..nTbS - 1$.

The $nTbS * 4 + 1$ neighbouring samples $p[x][y]$ that are constructed samples prior to the deblocking filter process, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$, are derived as follows:

- The neighbouring location $(xNbCmp, yNbCmp)$ is specified by:

$$(xNbCmp, yNbCmp) = (xTbCmp + x, yTbCmp + y) \quad (I-75)$$

- The current luma location $(xTbY, yTbY)$ and the neighbouring luma location $(xNbY, yNbY)$ are derived as follows:

$$(xTbY, yTbY) = (cIdx == 0) ? (xTbCmp, yTbCmp) : (xTbCmp * SubWidthC, yTbCmp * SubHeightC) \quad (I-76)$$

$$(xNbY, yNbY) = (cIdx == 0) ? (xNbCmp, yNbCmp) : (xNbCmp * SubWidthC, yNbCmp * SubHeightC) \quad (I-77)$$

- The availability derivation process for a block in z-scan order as specified in clause 6.4.1 is invoked with the current luma location $(xCurr, yCurr)$ set equal to $(xTbY, yTbY)$ and the neighbouring luma location $(xNbY, yNbY)$ as inputs, and the output is assigned to `availableN`.
- Each sample $p[x][y]$ is derived as follows:
 - If one or more of the following conditions are true, the sample $p[x][y]$ is marked as "not available for intra prediction":
 - The variable `availableN` is equal to `FALSE`.
 - `CuPredMode[xNbY][yNbY]` is not equal to `MODE_INTRA` and `constrained_intra_pred_flag` is equal to 1.
 - Otherwise, the sample $p[x][y]$ is marked as "available for intra prediction" and the sample at the location $(xNbCmp, yNbCmp)$ is assigned to $p[x][y]$.

When at least one sample $p[x][y]$ with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$ is marked as "not available for intra prediction" and `predModeIntra` is not equal to `INTRA_SINGLE`, the reference sample substitution process for intra sample prediction in clause 8.4.4.2.2 is invoked with the samples $p[x][y]$ with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1, nTbS$, and `cIdx` as inputs, and the modified samples $p[x][y]$ with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$ as output.

Depending on the value of `predModeIntra`, the following ordered steps apply:

1. When `predModeIntra` is in the range of 0 to 34, inclusive, `intra_smoothing_disabled_flag` is equal to 0, and either `cIdx` is equal to 0 or `ChromaArrayType` is equal to 3, the filtering process of neighbouring samples specified in clause 8.4.4.2.3 is invoked with the sample array `p`, the transform block size `nTbS` and the colour component index `cIdx` as inputs, and the output is reassigned to the sample array `p`.
2. The intra sample prediction process according to `predModeIntra` applies as follows:
 - If `predModeIntra` is equal to `INTRA_PLANAR`, the corresponding intra prediction mode specified in clause 8.4.4.2.4 is invoked with the sample array `p` and the transform block size `nTbS` as inputs, and the output is the predicted sample array `predSamples`.
 - Otherwise, if `predModeIntra` is equal to `INTRA_DC`, the corresponding intra prediction mode specified in clause 8.4.4.2.5 is invoked with the sample array `p`, the transform block size `nTbS`, and the colour component index `cIdx` as inputs, and the output is the predicted sample array `predSamples`.
 - Otherwise, if `predModeIntra` is in the range of `INTRA_ANGULAR2..INTRA_ANGULAR34`, the corresponding intra prediction mode specified in clause 8.4.4.2.6 is invoked with the intra prediction mode `predModeIntra`, the sample array `p`, the transform block size `nTbS`, and the colour component index `cIdx` as inputs, and the output is the predicted sample array `predSamples`.
 - Otherwise, if `predModeIntra` is equal to `INTRA_WEDGE`, the corresponding intra prediction mode specified in clause 8.4.4.2.2 is invoked with the location $(xTbY, yTbY)$, the sample array `p`, and the transform block size `nTbS` as inputs, and the output is the predicted sample array `predSamples`.
 - Otherwise, if `predModeIntra` is equal to `INTRA_CONTOUR`, the corresponding intra prediction mode specified in clause 8.4.4.2.3 is invoked with the location $(xTbY, yTbY)$, the sample array `p`, and the transform block size `nTbS` as inputs, and the output is the predicted sample array `predSamples`.
 - Otherwise, if `predModeIntra` is equal to `INTRA_SINGLE`, the corresponding intra prediction mode specified in clause 8.4.4.2.4 is invoked with the location $(xTbY, yTbY)$, the sample array `p`, and the transform block size `nTbS` as inputs, and the output is the predicted sample array `predSamples`.

I.8.4.4.2.2 Specification of intra prediction mode INTRA_WEDGE

Inputs to this process are:

- a luma location (xTb , yTb) specifying the top-left sample of the current transform block relative to the top-left luma sample of the current picture,
- the neighbouring samples $p[x][y]$, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$,
- a variable $nTbS$ specifying the transform block size.

Output of this process are the predicted samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$.

The list `WedgePatternTable` and the variable `NumWedgePattern` are specified by the derivation process for a wedgelet partition pattern table in clause I.6.6.

The partition pattern $wedgePattern[x][y]$ with $x, y = 0..nTbS - 1$ is derived as follows:

$$wedgePattern = WedgePatternTable[\text{Log2}(nTbS)][wedge_full_tab_idx[xTb][yTb]] \quad (I-78)$$

The depth sub-block partition DC value derivation and assignment process as specified in clause I.8.4.4.2.5 is invoked with the neighbouring samples $p[x][y]$, the partition pattern $wedgePattern[x][y]$, the luma location (xTb , yTb), and the transform size $nTbS$ as inputs, and the output is assigned to $predSamples[x][y]$.

I.8.4.4.2.3 Specification of intra prediction mode INTRA_CONTOUR

Inputs to this process are:

- a luma location (xTb , yTb) specifying the top-left sample of the current transform block relative to the top-left luma sample of the current picture,
- the neighbouring samples $p[x][y]$, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$,
- a variable $nTbS$ specifying the transform block size.

Output of this process are the predicted samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$.

The partition pattern $contourPattern[x][y]$, with $x, y = 0..nTbS - 1$ is derived as follows:

- The variable `refSamples` is set equal to the reconstructed picture sample array S_L of the picture `TexturePic`.
- The variable `threshVal` is derived as follows:

$$\begin{aligned} threshVal = & (refSamples[xTb][yTb] + refSamples[xTb][yTb + nTbS - 1] \\ & + refSamples[xTb + nTbS - 1][yTb] + refSamples[xTb + nTbS - 1][yTb + nTbS - 1]) \gg 2 \end{aligned} \quad (I-79)$$

- For $x = 0..nTbS - 1$ and $y = 0..nTbS - 1$, the following applies:

$$contourPattern[x][y] = (refSamples[xTb + x][yTb + y] > threshVal) \quad (I-80)$$

The depth sub-block partition DC value derivation and assignment process as specified in clause I.8.4.4.2.5 is invoked with the neighbouring samples $p[x][y]$, the partition pattern $contourPattern[x][y]$, the luma location (xTb , yTb), and the transform size $nTbS$ as inputs, and the output is assigned to $predSamples[x][y]$.

I.8.4.4.2.4 Specification of intra prediction mode INTRA_SINGLE

Inputs to this process are:

- a luma location (xTb , yTb) specifying the top-left sample of the current transform block relative to the top-left luma sample of the current picture,
- the neighbouring samples $p[x][y]$, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$,
- a variable $nTbS$ specifying the transform block size.

Output of this process are the predicted samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$.

Depending on the value of $skip_intra_mode_idx[xTb][yTb]$, the luma location (xN , yN) is derived as follows:

- If $skip_intra_mode_idx[xTb][yTb]$ is equal to 2, (xN , yN) is set equal to ($-1, nTbS \gg 1$).
- Otherwise ($skip_intra_mode_idx[xTb][yTb]$ is equal to 3), (xN , yN) is set equal to ($nTbS \gg 1, -1$).

The variable `singleSampleVal` is derived as follows:

- If $p[xN][yN]$ is marked as "available for intra prediction", `singleSampleVal` is set equal to $p[xN][yN]$.

- Otherwise ($p[x][y]$ is marked as "not available for intra prediction"), $singleSampleVal$ is set equal to $(1 \ll (\text{BitDepth}_Y - 1))$

The values of the prediction samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$, are derived as follows:

$$predSamples[x][y] = singleSampleVal \quad (I-81)$$

I.8.4.4.2.5 Depth sub-block partition DC value derivation and assignment process

Inputs to this process are:

- the neighbouring samples $p[x][y]$, with $x = -1, y = -1..nTbS * 2 - 1$ and $x = 0..nTbS * 2 - 1, y = -1$,
- a partition pattern $partitionPattern[x][y]$, with $x, y = 0..nTbS - 1$, specifying the sub-block partitions of the current prediction block,
- a luma location (xTb, yTb) specifying the top-left sample of the current transform block relative to the top-left luma sample of the current picture,
- a variable $nTbS$ specifying the transform block size.

Output of this process are the predicted samples $predSamples[x][y]$, with $x, y = 0..nTbS - 1$.

The variables $vertEdgeFlag$ and $horEdgeFlag$ are derived as follows:

$$vertEdgeFlag = (partitionPattern[0][0] \neq partitionPattern[nTbS - 1][0]) \quad (I-82)$$

$$horEdgeFlag = (partitionPattern[0][0] \neq partitionPattern[0][nTbS - 1]) \quad (I-83)$$

The variables $dcValBR$ and $dcValLT$ are derived as follows:

- If $vertEdgeFlag$ is equal to $horEdgeFlag$, the following applies:

- The variable $dcValBR$ is derived as follows:

- If $horEdgeFlag$ is equal to 1, the following applies:

$$dcValBR = ((p[-1][nTbS - 1] + p[nTbS - 1][-1]) \gg 1) \quad (I-84)$$

- Otherwise ($horEdgeFlag$ is equal to 0), the following applies:

$$vertAbsDiff = \text{Abs}(p[-1][0] - p[-1][nTbS * 2 - 1]) \quad (I-85)$$

$$horAbsDiff = \text{Abs}(p[0][-1] - p[nTbS * 2 - 1][-1]) \quad (I-86)$$

$$dcValBR = (horAbsDiff > vertAbsDiff) ? p[nTbS * 2 - 1][-1] : p[-1][nTbS * 2 - 1] \quad (I-87)$$

- The variable $dcValLT$ is derived as follows:

$$dcValLT = (p[-1][0] + p[0][-1]) \gg 1 \quad (I-88)$$

- Otherwise ($horEdgeFlag$ is not equal to $vertEdgeFlag$), the following applies:

$$dcValBR = horEdgeFlag ? p[-1][nTbS - 1] : p[nTbS - 1][-1] \quad (I-89)$$

$$dcValLT = horEdgeFlag ? p[(nTbS - 1) \gg 1][-1] : p[-1][(nTbS - 1) \gg 1] \quad (I-90)$$

The predicted sample values $predSamples[x][y]$ are derived as follows:

- For x in the range of 0 to $(nTbS - 1)$, inclusive, the following applies:
 - For y in the range of 0 to $(nTbS - 1)$, inclusive, the following applies:

- The variables $predDcVal$ and $dcOffset$ are derived as follows:

$$predDcVal = (partitionPattern[x][y] == partitionPattern[0][0]) ? dcValLT : dcValBR \quad (I-91)$$

$$dcOffset = DcOffset[xTb][yTb][partitionPattern[x][y]] \quad (I-92)$$

- If $DltFlag[nuh_layer_id]$ is equal to 0, the following applies:

$$predSamples[x][y] = predDcVal + dcOffset \quad (I-93)$$

- Otherwise ($DltFlag[nuh_layer_id]$ is equal to 1), the following applies:

$$predSamples[x][y] = DltIdxToVal[Clip1_Y(DltValToIdx[predDcVal] + dcOffset)] \quad (I-94)$$

I.8.4.4.3 Depth DC offset assignment process

Inputs to this process are:

- a luma location (x_{Tb} , y_{Tb}) specifying the top-left luma sample of the current transform block relative to the top-left luma sample of the current picture,
- a variable n_{TbS} specifying the transform block size.

Output of this process is a modified reconstructed picture S_L before deblocking filtering.

Depending on the value of $DltFlag[nuh_layer_id]$, the variable $dcVal$ is derived as follows:

- If $DltFlag[nuh_layer_id]$ is equal to 0, $dcVal$ is set equal to $DcOffset[x_{Tb}][y_{Tb}][0]$.
- Otherwise ($DltFlag[nuh_layer_id]$ is equal to 1), $dcVal$ is derived as follows:

$$dcPred = (S_L[x_{Tb}][y_{Tb}] + S_L[x_{Tb}][y_{Tb} + n_{TbS} - 1] + S_L[x_{Tb} + n_{TbS} - 1][y_{Tb}] + S_L[x_{Tb} + n_{TbS} - 1][y_{Tb} + n_{TbS} - 1] + 2) >> 2 \quad (I-95)$$

$$dcVal = DltIdxToVal[Clip1_Y(DltValToIdx[dcPred] + DcOffset[x_{Tb}][y_{Tb}][0])] - dcPred \quad (I-96)$$

For $x, y = 0..n_{TbS} - 1$, the variable $S_L[x][y]$ is modified as follows:

$$S_L[x_{Tb} + x][y_{Tb} + y] = Clip1_Y(S_L[x_{Tb} + x][y_{Tb} + y] + dcVal) \quad (I-97)$$

I.8.5 Decoding process for coding units coded in inter prediction mode

I.8.5.1 General decoding process for coding units coded in inter prediction mode

Inputs to this process are:

- a luma location (x_{Cb} , y_{Cb}) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable $\log2CbSize$ specifying the size of the current coding block.

Output of this process is a modified reconstructed picture before deblocking filtering.

The derivation process for quantization parameters as specified in clause 8.6.1 is invoked with the luma location (x_{Cb} , y_{Cb}) as input.

The variable $nCbS_L$ is set equal to $1 \ll \log2CbSize$. When $ChromaArrayType$ is not equal to 0, the variable $nCbSw_C$ is set equal to $(1 \ll \log2CbSize) / SubWidthC$ and the variable $nCbSh_C$ is set equal to $(1 \ll \log2CbSize) / SubHeightC$.

The decoding process for coding units coded in inter prediction mode consists of following ordered steps:

1. When $DisparityDerivationFlag$ is equal to 1, the following applies:
 - If $DepthFlag$ is equal to 0, the derivation process for a disparity vector for texture layers as specified in clause I.8.5.5 is invoked with the luma location (x_{Cb} , y_{Cb}) and the coding block size $nCbS_L$ as inputs.
 - Otherwise ($DepthFlag$ is equal to 1), the derivation process for a disparity vector for depth layers as specified in clause I.8.5.6 is invoked with the luma location (x_{Cb} , y_{Cb}) and the coding block size $nCbS_L$ as inputs.
2. The inter prediction process as specified in clause I.8.5.2 is invoked with the luma location (x_{Cb} , y_{Cb}) and the luma coding block size $\log2CbSize$ as inputs, and the output is the array $predSamples_L$ and, when $ChromaArrayType$ is not equal to 0, the arrays $predSamples_{Cb}$, and $predSamples_{Cr}$.
3. The decoding process for the residual signal of coding units coded in inter prediction mode specified in clause I.8.5.4 is invoked with the luma location (x_{Cb} , y_{Cb}) and the luma coding block size $\log2CbSize$ as inputs, and the outputs are the array $resSamples_L$ and, when $ChromaArrayType$ is not equal to 0, the arrays $resSamples_{Cb}$, and $resSamples_{Cr}$.
4. The reconstructed samples of the current coding unit are derived as follows:
 - The picture construction process prior to in-loop filtering for a colour component as specified in clause 8.6.7 is invoked with the luma coding block location (x_{Cb} , y_{Cb}), the variable $nCurrSw$ set equal to $nCbS_L$, the variable $nCurrSh$ set equal to $nCbS_L$, the variable $cIdx$ set equal to 0, the $(nCbS_L) \times (nCbS_L)$ array $predSamples$ set equal to $predSamples_L$, and the $(nCbS_L) \times (nCbS_L)$ array $resSamples$ set equal to $resSamples_L$ as inputs.
 - When $ChromaArrayType$ is not equal to 0, the picture construction process prior to in-loop filtering for a colour component as specified in clause 8.6.7 is invoked with the chroma coding block location ($x_{Cb} / SubWidthC$, $y_{Cb} / SubHeightC$), the variable $nCurrSw$ set equal to $nCbSw_C$, the variable $nCurrSh$

set equal to $nCbSh_C$, the variable $cIdx$ set equal to 1, the $(nCbSw_C) \times (nCbSh_C)$ array $predSamples$ set equal to $predSamples_{Cb}$, and the $(nCbSw_C) \times (nCbSh_C)$ array $resSamples$ set equal to $resSamples_{Cb}$ as inputs.

- When $ChromaArrayType$ is not equal to 0, the picture construction process prior to in-loop filtering for a colour component as specified in clause 8.6.7 is invoked with the chroma coding block location ($xCb / SubWidthC$, $yCb / SubHeightC$), the variable $nCurrSw$ set equal to $nCbSw_C$, the variable $nCurrSh$ set equal to $nCbSh_C$, the variable $cIdx$ set equal to 2, the $(nCbSw_C) \times (nCbSh_C)$ array $predSamples$ set equal to $predSamples_{Cr}$, and the $(nCbSw_C) \times (nCbSh_C)$ array $resSamples$ set equal to $resSamples_{Cr}$ as inputs.

I.8.5.2 Inter prediction process

The specifications in clause 8.5.2 apply with the following modification:

- All invocations of the process specified in clause 8.5.3 are replaced with invocations of the process specified in clause I.8.5.3.

I.8.5.3 Decoding process for prediction units in inter prediction mode

I.8.5.3.1 General

Inputs to this process are:

- a luma location (xCb , yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (xBl , yBl) specifying the top-left sample of the current luma prediction block relative to the top-left sample of the current luma coding block,
- a variable $nCbS$ specifying the size of the current luma coding block,
- a variable $nPbW$ specifying the width of the current luma prediction block,
- a variable $nPbH$ specifying the height of the current luma prediction block,
- a variable $partIdx$ specifying the index of the current prediction unit within the current coding unit.

Outputs of this process are:

- an $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ of luma prediction samples, where $nCbS_L$ is derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $predSamples_{Cb}$ of chroma prediction samples for the component Cb , where $nCbSw_C$ and $nCbSh_C$ are derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $predSamples_{Cr}$ of chroma prediction samples for the component Cr , where $nCbSw_C$ and $nCbSh_C$ are derived as specified below.

The variable $nCbS_L$ is set equal to $nCbS$. When $ChromaArrayType$ is not equal to 0, the variable $nCbSw_C$ is set equal to $nCbS / SubWidthC$ and the variable $nCbSh_C$ is set equal to $nCbS / SubHeightC$.

The decoding process for prediction units in inter prediction mode consists of the following ordered steps:

1. The derivation process for motion vector components and reference indices as specified in clause I.8.5.3.2 is invoked with the luma coding block location (xCb , yCb), the luma prediction block location (xBl , yBl), the luma coding block size block $nCbS$, the luma prediction block width $nPbW$, the luma prediction block height $nPbH$, and the prediction unit index $partIdx$ as inputs, and the luma motion vectors $mvL0$ and $mvL1$, when $ChromaArrayType$ is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$, the reference indices $refIdxL0$ and $refIdxL1$, the prediction list utilization flags $predFlagL0$ and $predFlagL1$, and the flag $subPbMotionFlag$ as outputs.
2. Depending on the value of $subPbMotionFlag$ and $DbbpFlag[xCb][yCb]$, the following applies:
 - If both $subPbMotionFlag$ and $DbbpFlag[xCb][yCb]$ are equal to 0, the decoding process for inter sample prediction as specified in clause I.8.5.3.3.1 is invoked with the luma coding block location (xCb , yCb), the luma prediction block location (xBl , yBl), the luma coding block size block $nCbS$, the luma prediction block width $nPbW$, the luma prediction block height $nPbH$, the luma motion vectors $mvL0$ and $mvL1$, when $ChromaArrayType$ is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$, the reference indices $refIdxL0$ and $refIdxL1$, and the prediction list utilization flags $predFlagL0$ and $predFlagL1$ as inputs, and the inter prediction samples ($predSamples$) that are an $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ of prediction luma samples and, when $ChromaArrayType$ is not equal to 0, two $(nCbSw_C) \times (nCbSh_C)$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$ of prediction chroma samples, one for each of the chroma components Cb and Cr , as outputs.
 - Otherwise, if $subPbMotionFlag$ is equal to 1, the decoding process for inter sample prediction for rectangular

sub-block partitions as specified in clause I.8.5.3.4 is invoked with the luma coding block location (x_{Cb} , y_{Cb}), the luma prediction block location (x_{Bl} , y_{Bl}), the luma coding block size block n_{CbS} , the luma prediction block width n_{PbW} , and the luma prediction block height n_{PbH} as inputs, and the inter prediction samples that are an $(n_{CbS_L}) \times (n_{CbS_L})$ array $predSamples_L$ of prediction luma samples and, when ChromaArrayType is not equal to 0, two $(n_{CbSw_C}) \times (n_{CbSh_C})$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$ of chroma prediction samples, one for each of the chroma components Cb and Cr, as outputs.

- Otherwise ($DbbpFlag[x_{Cb}][y_{Cb}]$ is equal to 1), the decoding process for inter sample prediction for depth predicted sub-block partitions as specified in clause I.8.5.3.5 is invoked with the luma coding block location (x_{Cb} , y_{Cb}), the luma coding block size n_{CbS} , the luma motion vectors $mvL0$ and $mvL1$, when ChromaArrayType is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$, the reference indices $refIdxL0$ and $refIdxL1$, the prediction list utilization flags $predFlagL0$ and $predFlagL1$, and the variable $partIdx$ as inputs, and the inter prediction samples that are an $(n_{CbS_L}) \times (n_{CbS_L})$ array $predSamples_L$ of prediction luma samples and, when ChromaArrayType is not equal to 0, two $(n_{CbSw_C}) \times (n_{CbSh_C})$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$ of chroma prediction samples, one for each of the chroma components Cb and Cr, as outputs.

For use in derivation processes of variables invoked later in the decoding process, the following assignments are made for $x = x_{Bl} \cdot x_{Bl} + n_{PbW} - 1$ and $y = y_{Bl} \cdot y_{Bl} + n_{PbH} - 1$:

$$MvL0[x_{Cb} + x][y_{Cb} + y] = subPbMotionFlag ? SubPbArrayMvL0[x_{Cb} + x][y_{Cb} + y] : mvL0 \quad (I-98)$$

$$MvL1[x_{Cb} + x][y_{Cb} + y] = subPbMotionFlag ? SubPbArrayMvL1[x_{Cb} + x][y_{Cb} + y] : mvL1 \quad (I-99)$$

$$RefIdxL0[x_{Cb} + x][y_{Cb} + y] = subPbMotionFlag ? SubPbArrayRefIdxL0[x_{Cb} + x][y_{Cb} + y] : refIdxL0 \quad (I-100)$$

$$RefIdxL1[x_{Cb} + x][y_{Cb} + y] = subPbMotionFlag ? SubPbArrayRefIdxL1[x_{Cb} + x][y_{Cb} + y] : refIdxL1 \quad (I-101)$$

$$PredFlagL0[x_{Cb} + x][y_{Cb} + y] = subPbMotionFlag ? SubPbArrayPredFlagL0[x_{Cb} + x][y_{Cb} + y] : predFlagL0 \quad (I-102)$$

$$PredFlagL1[x_{Cb} + x][y_{Cb} + y] = subPbMotionFlag ? SubPbArrayPredFlagL1[x_{Cb} + x][y_{Cb} + y] : predFlagL1 \quad (I-103)$$

I.8.5.3.2 Derivation process for motion vector components and reference indices

I.8.5.3.2.1 General

Inputs to this process are:

- a luma location (x_{Cb} , y_{Cb}) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (x_{Bl} , y_{Bl}) of the top-left sample of the current luma prediction block relative to the top-left sample of the current luma coding block,
- a variable n_{CbS} specifying the size of the current luma coding block,
- two variables n_{PbW} and n_{PbH} specifying the width and the height of the luma prediction block,
- a variable $partIdx$ specifying the index of the current prediction unit within the current coding unit.

Outputs of this process are:

- the luma motion vectors $mvL0$ and $mvL1$,
- when ChromaArrayType is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$,
- the reference indices $refIdxL0$ and $refIdxL1$,
- the prediction list utilization flags $predFlagL0$ and $predFlagL1$,
- the flag $subPbMotionFlag$ specifying, whether specifying whether the current PU is coded using sub-block partitions.

Let (x_{Pb} , y_{Pb}) specify the top-left sample location of the current luma prediction block relative to the top-left luma sample of the current picture where $x_{Pb} = x_{Cb} + x_{Bl}$ and $y_{Pb} = y_{Cb} + y_{Bl}$.

Let the variables $currPic$ and LX be the current picture and $RefPicListX$, with X being 0 or 1, of the current picture, respectively.

The function $LongTermRefPic(aPic, aPb, refIdx, LX)$, with X being 0 or 1, is defined as follows:

- If the picture with index refIdx from reference picture list LX of the slice containing prediction block aPb in the picture aPic was marked as "used for long-term reference" at the time when aPic was the current picture, $\text{LongTermRefPic}(\text{aPic}, \text{aPb}, \text{refIdx}, \text{LX})$ is equal to 1.
- Otherwise, $\text{LongTermRefPic}(\text{aPic}, \text{aPb}, \text{refIdx}, \text{LX})$ is equal to 0.

The variables vspMcFlag , ivMcFlag , and subPbMotionFlag are set equal to 0.

For the derivation of the variables mvL0 and mvL1 , refIdxL0 and refIdxL1 , as well as predFlagL0 and predFlagL1 , the following applies:

- If $\text{merge_flag}[\text{xPb}][\text{yPb}]$ is equal to 1, the derivation process for luma motion vectors for merge mode as specified in clause I.8.5.3.2.7 is invoked with the luma location (xCb, yCb) , the luma location (xPb, yPb) , the variables nCbS , nPbW , nPbH , and the partition index partIdx as inputs, and the output being the luma motion vectors mvL0 , mvL1 , the reference indices refIdxL0 , refIdxL1 , the prediction list utilization flags predFlagL0 and predFlagL1 , the flag ivMcFlag , the flag vspMcFlag , and the flag subPbMotionFlag .
- Otherwise, for X being replaced by either 0 or 1 in the variables predFlagLX , mvLX , and refIdxLX , in PRED_LX , and in the syntax elements ref_idx_IX and MvdLX , the following applies:
 1. The variables refIdxLX and predFlagLX are derived as follows:
 - If $\text{inter_pred_idc}[\text{xPb}][\text{yPb}]$ is equal to PRED_LX or PRED_BI ,

$$\text{refIdxLX} = \text{ref_idx_IX}[\text{xPb}][\text{yPb}] \quad (\text{I-104})$$

$$\text{predFlagLX} = 1 \quad (\text{I-105})$$
 - Otherwise, the variables refIdxLX and predFlagLX are specified by:

$$\text{refIdxLX} = -1 \quad (\text{I-106})$$

$$\text{predFlagLX} = 0 \quad (\text{I-107})$$
 2. The variable mvdLX is derived as follows:

$$\text{mvdLX}[0] = \text{MvdLX}[\text{xPb}][\text{yPb}][0] \quad (\text{I-108})$$

$$\text{mvdLX}[1] = \text{MvdLX}[\text{xPb}][\text{yPb}][1] \quad (\text{I-109})$$
 3. When predFlagLX is equal to 1, the derivation process for luma motion vector prediction in clause I.8.5.3.2.3 is invoked with the luma coding block location (xCb, yCb) , the coding block size nCbS , the luma prediction block location (xPb, yPb) , the variables nPbW , nPbH , refIdxLX , and the partition index partIdx as inputs, and the output being mvpLX .
 4. When predFlagLX is equal to 1, the luma motion vector mvLX is derived as follows:

$$\text{uLX}[0] = (\text{mvpLX}[0] + \text{mvdLX}[0] + 2^{16}) \% 2^{16} \quad (\text{I-110})$$

$$\text{mvLX}[0] = (\text{uLX}[0] \geq 2^{15}) ? (\text{uLX}[0] - 2^{16}) : \text{uLX}[0] \quad (\text{I-111})$$

$$\text{uLX}[1] = (\text{mvpLX}[1] + \text{mvdLX}[1] + 2^{16}) \% 2^{16} \quad (\text{I-112})$$

$$\text{mvLX}[1] = (\text{uLX}[1] \geq 2^{15}) ? (\text{uLX}[1] - 2^{16}) : \text{uLX}[1] \quad (\text{I-113})$$

NOTE – The resulting values of $\text{mvLX}[0]$ and $\text{mvLX}[1]$ as specified above will always be in the range of -2^{15} to $2^{15} - 1$, inclusive.

When ChromaArrayType is not equal to 0 and predFlagLX , with X being 0 or 1, is equal to 1, the derivation process for chroma motion vectors in clause 8.5.3.2.10 is invoked with mvLX as input, and the output being mvCLX .

For use in derivation processes of variables invoked later in the decoding process, the following assignments are made for $\text{x} = \text{xPb}..(\text{xPb} + \text{nPbW} - 1)$, $\text{y} = \text{yPb}..(\text{yPb} + \text{nPbH} - 1)$:

$$\text{IvMcFlag}[\text{x}][\text{y}] = \text{ivMcFlag} \quad (\text{I-114})$$

$$\text{VspMcFlag}[\text{x}][\text{y}] = \text{vspMcFlag} \quad (\text{I-115})$$

I.8.5.3.2.2 Derivation process for an initial merge candidate list

The specifications in clause 8.5.3.2.2 apply with the following modifications:

- Steps 9 and 10 are removed.
- "When slice_type is equal to B, the derivation process for combined bi-predictive merging candidates" is replaced with "When slice_type is equal to B and numCurrMergeCand is less than 5, the derivation process for combined bi-predictive merging candidates".

- "derivation process for merging candidates from neighbouring prediction unit partitions in clause 8.5.3.2.3" is replaced with "derivation process for merging candidates from neighbouring prediction unit partitions in clause I.8.5.3.2.3".
- "temporal luma motion vector prediction in clause 8.5.3.2.8 is invoked" is replaced with "temporal luma motion vector prediction in clause I.8.5.3.2.5 is invoked".
- The outputs of the process are replaced with:
 - the modified luma location (x_{Pb} , y_{Pb}) of the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
 - the variables n_{PbW} and n_{PbH} specifying the modified width and the height of the luma prediction block,
 - the modified variable $partIdx$ specifying the modified index of the current prediction unit within the current coding unit,
 - the original luma location (x_{OrigP} , y_{OrigP}) of the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
 - the variables $n_{OrigPbW}$ and $n_{OrigPbH}$ specifying the original width and the height of the luma prediction block,
 - the merging candidate list, $mergeCandList$,
 - the luma motion vectors $mvL0N$ and $mvL1N$, with N being replaced by all elements of $mergeCandList$,
 - the reference indices $refIdxL0N$ and $refIdxL1N$, with N being replaced by all elements of $mergeCandList$,
 - the prediction list utilization flags $predFlagL0N$ and $predFlagL1N$, with N being replaced by all elements of $mergeCandList$.

I.8.5.3.2.3 Derivation process for spatial merging candidates

The specifications in clause 8.5.3.2.3 apply with the following modifications and additions:

- The function $differentMotionLoc(xN, yN, xM, yM)$ is specified as follows:
 - If one or more of the following conditions are true, for X in the range of 0 to 1, inclusive, $differentMotionLoc(xN, yN, xM, yM)$ is set equal to 1:
 - $PredFlagLX[xN][yN]$ is not equal to $PredFlagLX[xM][yM]$.
 - $MvLX[xN][yN]$ is not equal to $MvLX[xM][yM]$.
 - $RefIdxLX[xN][yN]$ is not equal to $RefIdxLX[xM][yM]$.
 - Otherwise, $differentMotionLoc(xN, yN, xM, yM)$ is set equal to 0.
- "the prediction units covering the luma locations (x_{NbA_1} , y_{NbA_1}) and (x_{NbB_1} , y_{NbB_1}) have the same motion vectors and the same reference indices" is replaced with " $differentMotionLoc(x_{NbA_1}, y_{NbA_1}, x_{NbB_1}, y_{NbB_1})$ is equal to 0".
- "the prediction units covering the luma locations (x_{NbB_1} , y_{NbB_1}) and (x_{NbB_0} , y_{NbB_0}) have the same motion vectors and the same reference indices" is replaced with " $differentMotionLoc(x_{NbB_1}, y_{NbB_1}, x_{NbB_0}, y_{NbB_0})$ is equal to 0".
- "the prediction units covering the luma locations (x_{NbA_1} , y_{NbA_1}) and (x_{NbA_0} , y_{NbA_0}) have the same motion vectors and the same reference indices" is replaced with " $differentMotionLoc(x_{NbA_1}, y_{NbA_1}, x_{NbA_0}, y_{NbA_0})$ is equal to 0".
- "prediction units covering the luma locations (x_{NbA_1} , y_{NbA_1}) and (x_{NbB_2} , y_{NbB_2}) have the same motion vectors and the same reference indices" is replaced with " $differentMotionLoc(x_{NbA_1}, y_{NbA_1}, x_{NbB_2}, y_{NbB_2})$ is equal to 0".
- "the prediction units covering the luma locations (x_{NbB_1} , y_{NbB_1}) and (x_{NbB_2} , y_{NbB_2}) have the same motion vectors and the same reference indices" is replaced with " $differentMotionLoc(x_{NbB_1}, y_{NbB_1}, x_{NbB_2}, y_{NbB_2})$ is equal to 0".

I.8.5.3.2.4 Derivation process for luma motion vector prediction

The specifications in clause 8.5.3.2.6 apply with the following modifications:

- "temporal luma motion vector prediction in clause 8.5.3.2.8 is invoked" is replaced by "temporal luma motion vector prediction in clause I.8.5.3.2.5 is invoked".

I.8.5.3.2.5 Derivation process for temporal luma motion vector prediction

Inputs to this process are:

- a luma location (xPb, yPb) specifying the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables nPbW and nPbH specifying the width and the height of the luma prediction block,
- a reference index refIdxLX, with X being 0 or 1.

Outputs of this process are:

- the motion vector prediction mvLXCol,
- the availability flag availableFlagLXCol.

The variable currPb specifies the current luma prediction block at luma location (xPb, yPb).

The variables mvLXCol and availableFlagLXCol are derived as follows:

- If slice_temporal_mvp_enabled_flag is equal to 0, both components of mvLXCol are set equal to 0 and availableFlagLXCol is set equal to 0.
- Otherwise, the following ordered steps apply:

1. The bottom right collocated motion vector is derived as follows:

$$xColBr = xPb + nPbW \quad (I-116)$$

$$yColBr = yPb + nPbH \quad (I-117)$$

- If $yPb \gg CtbLog2SizeY$ is equal to $yColBr \gg CtbLog2SizeY$, $yColBr$ is less than $pic_height_in_luma_samples$ and $xColBr$ is less than $pic_width_in_luma_samples$, the following applies:
 - The luma location (xColPb, yColPb) is set equal to $((xColBr \gg 4) \ll 4, (yColBr \gg 4) \ll 4)$.
 - The variable colPb specifies the luma prediction block covering the modified location given by (xColPb, yColPb) inside the collocated picture specified by ColPic.
 - Depending on merge_flag[xPb][yPb], the following applies:
 - If merge_flag[xPb][yPb] is equal to 0, the derivation process for collocated motion vectors as specified in clause 8.5.3.2.9 is invoked with currPb, colPb, (xColPb, yColPb) and refIdxLX as inputs, and the output is assigned to mvLXCol and availableFlagLXCol.
 - Otherwise (merge_flag[xPb][yPb] is equal to 1), the derivation process for collocated motion vectors for merge mode as specified in clause I.8.5.3.2.6 is invoked with currPb, colPb, (xColPb, yColPb) and refIdxLX as inputs, and the output is assigned to mvLXCol and availableFlagLXCol.
- Otherwise, both components of mvLXCol are set equal to 0 and availableFlagLXCol is set equal to 0.

2. When availableFlagLXCol is equal to 0, the central collocated motion vector is derived as follows:

$$xColCtr = xPb + (nPbW \gg 1) \quad (I-118)$$

$$yColCtr = yPb + (nPbH \gg 1) \quad (I-119)$$

- The luma location (xColPb, yColPb) is set equal to $((xColCtr \gg 4) \ll 4, (yColCtr \gg 4) \ll 4)$.
- The variable colPb specifies the luma prediction block covering the modified location given by (xColPb, yColPb) inside the collocated picture specified by ColPic.
- Depending on merge_flag[xPb][yPb], the following applies:
 - If merge_flag[xPb][yPb] is equal to 0, the derivation process for collocated motion vectors as specified in clause 8.5.3.2.9 is invoked with currPb, colPb, (xColPb, yColPb) and refIdxLX as inputs, and the output is assigned to mvLXCol and availableFlagLXCol.
 - Otherwise (merge_flag[xPb][yPb] is equal to 1), the derivation process for collocated motion vectors for merge mode as specified in clause I.8.5.3.2.6 is invoked with currPb, colPb, (xColPb, yColPb) and refIdxLX as inputs, and the output is assigned to mvLXCol and availableFlagLXCol.

1.8.5.3.2.6 Derivation process for collocated motion vectors for merge mode

Inputs to this process are:

- a variable currPb specifying the current prediction block,
- a variable colPb specifying the collocated prediction block inside the collocated picture specified by ColPic,
- a luma location (xColPb, yColPb) specifying a sample inside the collocated luma prediction block specified by colPb relative to the top-left luma sample of the collocated picture specified by ColPic,
- a reference index refIdxLX, with X being 0 or 1.

Outputs of this process are:

- the motion vector prediction mvLXCol,
- the availability flag availableFlagLXCol.

The arrays predFlagL0Col[x][y], mvL0Col[x][y], and refIdxL0Col[x][y] are set equal to PredFlagL0[x][y], MvL0[x][y], and RefIdxL0[x][y], respectively, of the collocated picture specified by ColPic, and the arrays predFlagL1Col[x][y], mvL1Col[x][y], and refIdxL1Col[x][y] are set equal to PredFlagL1[x][y], MvL1[x][y], and RefIdxL1[x][y], respectively, of the collocated picture specified by ColPic.

The variables mvLXCol and availableFlagLXCol are derived as follows:

- If colPb is coded in an intra prediction mode, both components of mvLXCol are set equal to 0 and availableFlagLXCol is set equal to 0.
- Otherwise, the following applies:
 - The motion vector mvCol, the reference index refIdxCol, and the reference list identifier listCol are derived as follows:
 - If predFlagL0Col[xColPb][yColPb] is equal to 0, mvCol, refIdxCol, and listCol are set equal to mvL1Col[xColPb][yColPb], refIdxL1Col[xColPb][yColPb], and L1, respectively.
 - Otherwise, if predFlagL0Col[xColPb][yColPb] is equal to 1 and predFlagL1Col[xColPb][yColPb] is equal to 0, mvCol, refIdxCol, and listCol are set equal to mvL0Col[xColPb][yColPb], refIdxL0Col[xColPb][yColPb], and L0, respectively.
 - Otherwise (predFlagL0Col[xColPb][yColPb] is equal to 1 and predFlagL1Col[xColPb][yColPb] is equal to 1), the following assignments are made:
 - If NoBackwardPredFlag is equal to 1, mvCol, refIdxCol, and listCol are set equal to mvLXCol[xColPb][yColPb], refIdxLXCol[xColPb][yColPb], and LX, respectively.
 - Otherwise, mvCol, refIdxCol, and listCol are set equal to mvLNCol[xColPb][yColPb], refIdxLNCol[xColPb][yColPb], and LN, respectively, with N being the value of collocated_from_10_flag.
 - The motion vector mvLXCol and availableFlagLXCol are derived as follows:
 - The variables curLtFlag and colLtFlag are derived as follows:

$$\text{curLtFlag} = \text{LongTermRefPic}(\text{CurrPic}, \text{currPb}, \text{refIdxLX}, \text{LX}) \quad (\text{I-120})$$

$$\text{colLtFlag} = \text{LongTermRefPic}(\text{ColPic}, \text{colPb}, \text{refIdxCol}, \text{listCol}) \quad (\text{I-121})$$
 - When curLtFlag is not equal to colLtFlag and AltRefIdxLX is not equal to -1, the variables AltRefFlagLX, refIdxLX, and curLtFlag are modified as follows:

$$\text{AltRefFlagLX} = 1 \quad (\text{I-122})$$

$$\text{refIdxLX} = \text{AltRefIdxLX} \quad (\text{I-123})$$

$$\text{curLtFlag} = \text{LongTermRefPic}(\text{CurrPic}, \text{currPb}, \text{refIdxLX}, \text{LX}) \quad (\text{I-124})$$
 - The motion vector mvLXCol is modified as follows:
 - If curLtFlag is not equal to colLtFlag, both components of mvLXCol are set equal to 0 and availableFlagLXCol is set equal to 0.
 - Otherwise, the variable availableFlagLXCol is set equal to 1, refPicListCol[refIdxCol] is set to be the picture with reference index refIdxCol in the reference picture list listCol of the slice containing

prediction block colPb in the collocated picture specified by ColPic, and the following applies:

- The variables colDiff and currDiff are set equal to 0 and modified as follows:
 - If curLtFlag is equal to 0, the following applies:

$$\text{colDiff} = \text{DiffPicOrderCnt}(\text{ColPic}, \text{refPicListCol}[\text{refIdxCol}]) \quad (\text{I-125})$$

$$\text{currDiff} = \text{DiffPicOrderCnt}(\text{CurrPic}, \text{RefPicListX}[\text{refIdxLX}]) \quad (\text{I-126})$$
 - Otherwise (curLtFlag is equal to 1), when IvMvScalEnabledFlag is equal to 1, the following applies:

$$\text{colDiff} = \text{ViewIdVal}(\text{ColPic}) - \text{ViewIdVal}(\text{refPicListCol}[\text{refIdxCol}]) \quad (\text{I-127})$$

$$\text{currDiff} = \text{ViewIdVal}(\text{CurrPic}) - \text{ViewIdVal}(\text{RefPicListX}[\text{refIdxLX}]) \quad (\text{I-128})$$
- Depending on the values of colDiff and currDiff, the following applies:
 - If colDiff is equal to currDiff, or colDiff is equal to 0, or currDiff is equal to 0, mvLXCol is derived as follows:

$$\text{mvLXCol} = \text{mvCol} \quad (\text{I-129})$$
 - Otherwise, mvLXCol is derived as a scaled version of the motion vector mvCol as follows:

$$\text{tx} = (16384 + (\text{Abs}(\text{td}) \gg 1)) / \text{td} \quad (\text{I-130})$$

$$\text{distScaleFactor} = \text{Clip3}(-4096, 4095, (\text{tb} * \text{tx} + 32) \gg 6) \quad (\text{I-131})$$

$$\text{mvLXCol} = \text{Clip3}(-32768, 32767, \text{Sign}(\text{distScaleFactor} * \text{mvCol}) * ((\text{Abs}(\text{distScaleFactor} * \text{mvCol}) + 127) \gg 8)) \quad (\text{I-132})$$

where td and tb are derived as follows:

$$\text{td} = \text{Clip3}(-128, 127, \text{colDiff}) \quad (\text{I-133})$$

$$\text{tb} = \text{Clip3}(-128, 127, \text{currDiff}) \quad (\text{I-134})$$

I.8.5.3.2.7 Derivation process for luma motion vectors for merge mode

This process is only invoked when merge_flag[xPb][yPb] is equal to 1, where (xPb, yPb) specifies the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture.

Inputs to this process are:

- a luma location (xCb, yCb) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (xPb, yPb) of the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- a variable nCbS specifying the size of the current luma coding block,
- two variables nPbW and nPbH specifying the width and the height of the luma prediction block,
- a variable partIdx specifying the index of the current prediction unit within the current coding unit.

Outputs of this process are:

- the luma motion vectors mvL0 and mvL1,
- the reference indices refIdxL0 and refIdxL1,
- the prediction list utilization flags predFlagL0 and predFlagL1,
- the flag ivMcFlag specifying whether the current PU is coded using an inter-view predicted merge candidate,
- the flag vspMcFlag specifying whether the current PU is coded using the view synthesis prediction merge candidate,
- the flag subPbMotionFlag specifying whether the current PU is coded using sub-block partitions.

The function differentMotion(N, M) is specified as follows:

- If one or more of the following conditions are true, for X in the range of 0 to 1, inclusive, differentMotion(N, M) is set equal to 1:

- predFlagLXN is not equal to predFlagLXM.
- mvLXN is not equal to mvLXM.
- refIdxLXN is not equal to refIdxLXM.
- Otherwise, differentMotion(N, M) is set equal to 0.

The variables AltRefFlagL0 and AltRefFlagL1 are set equal to 0.

The motion vectors mvL0 and mvL1, the reference indices refIdxL0 and refIdxL1, and the prediction utilization flags predFlagL0 and predFlagL1 are derived by the following ordered steps:

1. The derivation process for an initial merge candidate list as specified in clause I.8.5.3.2.2 is invoked with the luma location (xCb, yCb), the luma location (xPb, yPb), the variables nCbS, nPbW, nPbH, and the partition index partIdx as inputs, and the outputs being a modified luma location (xPb, yPb), the modified variables nPbW and nPbH, the modified variable partIdx, the luma location (xOrigP, yOrigP), the variables nOrigPbW and nOrigPbH, the merging candidate list initMergeCandList, the luma motion vectors mvL0N and mvL1N, the reference indices refIdxL0N and refIdxL1N, and the prediction list utilization flags predFlagL0N and predFlagL1N, with N being replaced by all elements of initMergeCandList.
2. For N being replaced by A₁, B₁, B₀, A₀ and B₂, the following applies:
 - If N is an element in initMergeCandList, availableFlagN is set equal to 1.
 - Otherwise (N is not an element in initMergeCandList), availableFlagN is set equal to 0.
3. Depending on the values of IvDiMcEnabledFlag, DispAvailFlag, and IlluCompFlag[xCb][yCb], the following applies:
 - If IvDiMcEnabledFlag is equal to 0, DispAvailFlag is equal to 0, or IlluCompFlag[xCb][yCb] is equal to 1, the flags availableFlagIV and availableFlagIVShift are set equal to 0.
 - Otherwise (IvDiMcEnabledFlag is equal to 1, DispAvailFlag is equal to 1, and IlluCompFlag[xCb][yCb] is equal to 0), the derivation process for inter-view predicted merging candidates as specified in clause I.8.5.3.2.8 is invoked with the luma location (xPb, yPb), and the variables nPbW and nPbH as inputs, and the availability flags availableFlagIV and availableFlagIVShift, the prediction list utilization flags predFlagLXIV and predFlagLXIVShift, the reference indices refIdxLXIV and refIdxLXIVShift, and the motion vectors mvLXIV and mvLXIVShift (with X in the range of 0 to 1, inclusive) as outputs.
4. Depending on the value of TexMcEnabledFlag, the texture merging candidate is derived as follows:
 - If TexMcEnabledFlag is equal to 0, the variable availableFlagT is set equal to 0.
 - Otherwise (TexMcEnabledFlag is equal to 1), the following applies:
 - The derivation process for sub-block partition motion vectors for an inter-layer predicted merging candidate as specified in clause I.8.5.3.2.9 is invoked with the luma location (xPb, yPb), the variables nPbW and nPbH, and the merging candidate indicator N equal to T as inputs, and the prediction utilization flag predFlagLXT, the reference index refIdxLXT, and the motion vector mvLXT (with X in the range of 0 to 1, inclusive) as outputs.
 - The flag availableFlagT is set equal to (predFlagL0T || predFlagL1T).
5. Depending on the values of IvDiMcEnabledFlag, DispAvailFlag, and DepthFlag, the following applies:
 - If IvDiMcEnabledFlag is equal to 0, DispAvailFlag is equal to 0, or DepthFlag is equal to 1, the flags availableFlagDI and availableFlagDIShift are set equal to 0.
 - Otherwise (IvDiMcEnabledFlag is equal to 1, DispAvailFlag is equal to 1, and DepthFlag is equal to 0), the derivation process for disparity information merging candidates as specified in clause I.8.5.3.2.12 is invoked with the luma location (xPb, yPb), and the variables nPbW and nPbH as inputs, and the availability flags availableFlagDI and availableFlagDIShift, the prediction list utilization flags predFlagLXDI and predFlagLXDIShift, the reference indices refIdxLXDI and refIdxLXDIShift, and the motion vectors mvLXDI and mvLXDIShift (with X in the range of 0 to 1, inclusive) as outputs.
6. Depending on the values of VspMcEnabledFlag, DispAvailFlag, IlluCompFlag[xCb][yCb], iv_res_pred_weight_idx[xCb][yCb], and DbppFlag[xCb][yCb], the following applies:
 - If one or more of the following conditions are true, the flag availableFlagVSP is set equal to 0:
 - VspMcEnabledFlag is equal to 0.

- DispAvailFlag is equal to 0.
- IlluCompFlag[xCb][yCb] is equal to 1.
- iv_res_pred_weight_idx[xCb][yCb] is not equal to 0.
- DbbpFlag[xCb][yCb] is equal to 1.
- Otherwise, the derivation process for a view synthesis prediction merging candidate as specified in clause I.8.5.3.2.13 is invoked with the luma locations (xPb, yPb) and the variables nPbW and nPbH as inputs, and the availability flag availableFlagVSP, the prediction list utilization flag predFlagLXVSP, the reference index refIdxLXVSP, and the motion vector mvLXVSP (with X in the range of 0 to 1, inclusive) as outputs.

7. The merging candidate list extMergeCandList is constructed as follows:

```

i = 0
if( availableFlagT )
    extMergeCandList[ i++ ] = T
if( availableFlagIV && ( !availableFlagT || differentMotion( T, IV ) ) )
    extMergeCandList[ i++ ] = IV
N = DepthFlag ? T : IV
if( availableFlagA1 && ( !availableFlagN || differentMotion( N, A1 ) ) )
    extMergeCandList[ i++ ] = A1
if( availableFlagB1 && ( !availableFlagN || differentMotion( N, B1 ) ) )
    extMergeCandList[ i++ ] = B1
if( availableFlagVSP && ( !availableFlagA1 || !VspMcFlag[ xPb - 1 ][ yPb + nPbH - 1 ] ) &&
    i < MaxNumMergeCand )
    extMergeCandList[ i++ ] = VSP
if( availableFlagB0 )
    extMergeCandList[ i++ ] = B0
if( availableFlagDI && ( !availableFlagA1 || differentMotion( A1, DI ) ) &&
    ( !availableFlagB1 || differentMotion( B1, DI ) ) && ( i < MaxNumMergeCand ) )
    extMergeCandList[ i++ ] = DI
if( availableFlagA0 && i < MaxNumMergeCand )
    extMergeCandList[ i++ ] = A0
if( availableFlagB2 && i < MaxNumMergeCand )
    extMergeCandList[ i++ ] = B2
if( availableFlagIVShift && i < MaxNumMergeCand &&
    ( !availableFlagIV || differentMotion( IV, IVShift ) ) )
    extMergeCandList[ i++ ] = IVShift
if( availableFlagDIShift && !availableFlagIVShift && i < MaxNumMergeCand )
    extMergeCandList[ i++ ] = DIShift
j = 0
while( i < MaxNumMergeCand ) {
    N = initMergeCandList[ j++ ]
    if( N != A1 && N != B1 && N != B0 && N != A0 && N != B2 )
        extMergeCandList[ i++ ] = N
}

```

8. The variable N is derived as follows:

- If (nOrigPbW + nOrigPbH) is equal to 12, the following applies:

$$N = \text{initMergeCandList}[\text{merge_idx}[\text{xOrigP}][\text{yOrigP}]] \quad (\text{I-137})$$

- Otherwise, ((nOrigPbW + nOrigPbH) is not equal to 12), the following applies:

$$N = \text{extMergeCandList}[\text{merge_idx}[\text{xOrigP}][\text{yOrigP}]] \quad (\text{I-138})$$

9. When N is equal to Col, the following applies for X in the range of 0 to 1, inclusive:

- When AltRefFlagLX is equal to 1, refIdxLXCol is set equal to AltRefIdxLX.

10. When availableFlagVSP is equal to 1, N is equal to A₁, and VspMcFlag[xPb - 1][yPb + nPbH - 1] is equal to 1, N is set equal to VSP.

11. The variable subPbMotionFlag is derived as follows:

$$\text{subPbMotionFlag} = (\text{!DepthFlag} \ \&\& \ \text{!DbbpFlag}[\text{xCb}][\text{yCb}] \ \&\& \ \text{N} == \text{IV}) \\ || \ \text{N} == \text{VSP} || \ \text{N} == \text{T} \quad (\text{I-139})$$

12. Depending on the value of subPbMotionFlag, the following applies:

- If subPbMotionFlag is equal to 0, the following applies, for X in the range of 0 to 1, inclusive:

$$\text{mvLX} = \text{mvLXN} \quad (\text{I-140})$$

$$\text{refIdxLX} = \text{refIdxLXN} \quad (\text{I-141})$$

$$\text{predFlagLX} = \text{predFlagLXN} \quad (\text{I-142})$$

- Otherwise (subPbMotionFlag is equal to 1), SubPbArrayPartSize is set equal to SubPbArrayPartSizeN and the following applies for X in the range of 0 to 1, inclusive:

$$\text{mvLX} = (0, 0) \quad (\text{I-143})$$

$$\text{SubPbArrayMvLX} = \text{SubPbArrayMvLXN} \quad (\text{I-144})$$

$$\text{SubPbArrayMvCLX} = \text{SubPbArrayMvCLXN} \quad (\text{I-145})$$

$$\text{refIdxLX} = -1 \quad (\text{I-146})$$

$$\text{SubPbArrayRefIdxLX} = \text{SubPbArrayRefIdxLXN} \quad (\text{I-147})$$

$$\text{predFlagLX} = 0 \quad (\text{I-148})$$

$$\text{SubPbArrayPredFlagLX} = \text{SubPbArrayPredFlagLXN} \quad (\text{I-149})$$

NOTE – When subPbMotionFlag is equal to 1, luma motion vectors, chroma motion vectors, reference indices, and prediction utilization flags are given in sub-block partition granularity in the arrays SubPbArrayPredFlagLX, SubPbArrayMvLX, SubPbArrayMvCLX, SubPbArrayRefIdxLX (with X in the range of 0 to 1, inclusive). Moreover, the width and height of the sub-block partitions is stored in the array SubPbArrayPartSize.

13. When all of the following conditions are true, refIdxL1 is set equal to -1 and predFlagL1 is set equal to 0:

- predFlagL0 and predFlagL1 are equal to 1.
- (nOrigPbW + nOrigPbH) is equal to 12 or DbbpFlag[xCb][yCb] is equal to 1.

14. The flag ivMcFlag is set equal to (N == IV || N == IVShift).

15. The flag vspMcFlag is set equal to (N == VSP).

I.8.5.3.2.8 Derivation process for inter-view predicted merging candidates

Inputs to this process are:

- a luma location (xPb, yPb) of the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables nPbW and nPbH specifying the width and the height of the current luma prediction block.

Outputs of this process are (with X in the range of 0 to 1, inclusive):

- the availability flags availableFlagIV and availableFlagIVShift specifying whether the inter-view predicted and shifted inter-view predicted merging candidates are available,
- the prediction list utilization flags predFlagLXIV and predFlagLXIVShift,
- the reference indices refIdxLXIV and refIdxLXIVShift,
- the motion vectors mvLXIV and mvLXIVShift.

The availability flags availableFlagIV and availableFlagIVShift are set equal to 0, and for X in the range of 0 to 1, inclusive, the following applies:

- The variables predFlagLXIV and predFlagLXIVShift are set equal to 0, the variables refIdxLXIV and refIdxLXIVShift are set equal to -1, and the motion vectors mvLXIV and mvLXIVShift are set equal to (0, 0).

The inter-view predicted merging candidate is derived by the following ordered steps:

1. Depending on the values of DbbpFlag[xPb][yPb] and DepthFlag, the following applies:
 - If DbbpFlag[xPb][yPb] is equal to 0 and DepthFlag is equal to 0, the derivation process for sub-block partition motion vectors for an inter-layer predicted merging candidate as specified in clause I.8.5.3.2.9 is

invoked with the luma location (xPb, yPb), the variables nPbW and nPbH, and the merging candidate indicator N equal to IV as inputs, and the outputs are the flag predFlagLXIV, the reference index refIdxLXIV, and the motion vector mvLXIV (with X in the range of 0 to 1, inclusive).

- Otherwise (DbbpFlag[xPb][yPb] is not equal to 0 or DepthFlag is equal to 1), the derivation process for motion vectors for an inter-view predicted merging candidate as specified in clause I.8.5.3.2.10 is invoked with the luma location (xPb, yPb), the variables nPbW and nPbH, and the disparity vector offset (xOff, yOff) equal to (0, 0) as inputs, and the outputs are the flag predFlagLXIV, the reference index refIdxLXIV, and the motion vector mvLXIV (with X in the range of 0 to 1, inclusive).

2. The availability flag availableFlagIV is set equal to (predFlagL0IV || predFlagL1IV).

When DepthFlag is equal to 0, the shifted inter-view predicted merging candidate is derived by the following ordered steps:

1. The derivation process for motion vectors for an inter-view predicted merging candidate as specified in clause I.8.5.3.2.10 is invoked with the luma location (xPb, yPb), the variables nPbW and nPbH, and the disparity vector offset (xOff, yOff) equal to (nPbW * 2, nPbH * 2) as inputs, and the outputs are the flag predFlagLXIVShift, the reference index refIdxLXIVShift, and the motion vector mvLXIVShift (with X in the range of 0 to 1, inclusive).
2. The availability flag availableFlagIVShift is set equal to (predFlagL0IVShift || predFlagL1IVShift).

I.8.5.3.2.9 Derivation process for sub-block partition motion vectors for an inter-layer predicted merging candidate

Inputs to this process are:

- a luma location (xPb, yPb) of the top-left sample of the current prediction luma block relative to the top-left luma sample of the current picture,
- two variables nPbW and nPbH specifying the width and the height of the current prediction block,
- a merging candidate indicator N.

Outputs of this process are (with X in the range of 0 to 1, inclusive):

- the prediction utilization flag predFlagLXN,
- the reference index refIdxLXN,
- the motion vector mvLXN.

For X in the range of 0 to 1, inclusive, the variable predFlagLXN is set equal to 0, the variable refIdxLXN is set equal to -1, the motion vector mvLXN is set equal to (0, 0).

The variables nSbW and nSbH specifying the width and height of the sub-block partitions and the luma location (xSbDef, ySbDef) of the default sub-block partition are derived as follows:

$$\text{subPbTmcSize} = 1 \ll (\log_2_texmc_sub_pb_size_minus3[\text{DepthFlag}] + 3) \quad (\text{I-150})$$

$$\text{subPbIvMcSize} = 1 \ll (\log_2_ivmc_sub_pb_size_minus3[\text{DepthFlag}] + 3) \quad (\text{I-151})$$

$$\text{minSize} = (N == T) ? \text{subPbTmcSize} : \text{subPbIvMcSize} \quad (\text{I-152})$$

$$\text{nSbW} = (\text{nPbW} \% \text{minSize} != 0 \mid \mid \text{nPbH} \% \text{minSize} != 0) ? \text{nPbW} : \text{minSize} \quad (\text{I-153})$$

$$\text{nSbH} = (\text{nPbW} \% \text{minSize} != 0 \mid \mid \text{nPbH} \% \text{minSize} != 0) ? \text{nPbH} : \text{minSize} \quad (\text{I-154})$$

$$(\text{xSbDef}, \text{ySbDef}) = (\text{xPb} + ((\text{nPbW} / \text{nSbW}) / 2) * \text{nSbW}, \text{yPb} + ((\text{nPbH} / \text{nSbH}) / 2) * \text{nSbH}) \quad (\text{I-155})$$

Depending on the value of N, the variables predFlagLXN, refIdxLXN, and mvLXN are derived as follows:

- If N is equal to IV, the derivation process for motion vectors for an inter-view predicted merging candidate as specified in clause I.8.5.3.2.10 is invoked with the luma location (xSbDef, ySbDef), the variables nSbW and nSbH, and the disparity vector offset (xOff, yOff) equal to (0, 0) as inputs, and the outputs are the flag predFlagLXN, the reference index refIdxLXN, and the motion vector mvLXN (with X in the range of 0 to 1, inclusive).
- Otherwise (N is equal to T), the derivation process for motion vectors for the texture merge candidate as specified in clause I.8.5.3.2.11 is invoked with the luma location (xSbDef, ySbDef), and the variables nSbW and nSbH as inputs, and the outputs are the flags predFlagLXN, the reference index refIdxLXN, and the motion vector mvLXN (with X in the range of 0 to 1, inclusive).

When predFlagL0N or predFlagL1N is equal to 1, the following applies:

- For $yBlk$ in the range of 0 to $(nPbH / nSbH - 1)$, inclusive, the following applies:
 - For $xBlk$ in the range of 0 to $(nPbW / nSbW - 1)$, inclusive, the following applies:
 - The luma location (xSb, ySb) of the current sub-block partition is derived as follows:

$$(xSb, ySb) = (xPb + xBlk * nSbW, yPb + yBlk * nSbH) \quad (I-156)$$
 - Depending on the value of N , the following applies:
 - If N is equal to IV, the derivation process for motion vectors for an inter-view predicted merging candidate as specified in clause I.8.5.3.2.10 is invoked with the luma location (xSb, ySb) , the variables $nSbW$ and $nSbH$, and the disparity vector offset $(xOff, yOff)$ equal to $(0, 0)$ as inputs, and the outputs are the flag $spPredFlagLX[xBlk][yBlk]$, the reference index $spRefIdxLX[xBlk][yBlk]$, and the motion vector $spMvLX[xBlk][yBlk]$ (with X in the range of 0 to 1, inclusive).
 - Otherwise (N is equal to T), the derivation process for motion vectors for the texture merge candidate as specified in clause I.8.5.3.2.11 is invoked with the luma location (xSb, ySb) , and the variables $nSbW$ and $nSbH$ as inputs, and the outputs are the flags $spPredFlagLX[xBlk][yBlk]$, the reference index $spRefIdxLX[xBlk][yBlk]$, and the motion vector $spMvLX[xBlk][yBlk]$ (with X in the range of 0 to 1, inclusive).
 - When $spPredFlagL0[xBlk][yBlk]$ and $spPredFlagL1[xBlk][yBlk]$ are both equal to 0, the following applies for X in the range of 0 to 1, inclusive:

$$spPredFlagLX[xBlk][yBlk] = predFlagLXN \quad (I-157)$$

$$spRefIdxLX[xBlk][yBlk] = refIdxLXN \quad (I-158)$$

$$spMvLX[xBlk][yBlk] = mvLXN \quad (I-159)$$
- For use in derivation processes of variables invoked later in the decoding process, the following assignments are made for $x = 0..nPbW - 1$ and $y = 0..nPbH - 1$:
 - The variable $SubPbArrayPartSizeN$ is derived as follows:

$$SubPbArrayPartSizeN[xPb + x][yPb + y] = (nSbW, nSbH) \quad (I-160)$$
 - For X in the range of 0 to 1, inclusive, the following applies:
 - The variables $SubPbArrayPredFlagLX$, $SubPbArrayMvLX$, and $SubPbArrayRefIdxLX$ are derived as follows:

$$SubPbArrayPredFlagLXN[xPb + x][yPb + y] = spPredFlagLX[x / nSbW][y / nSbH] \quad (I-161)$$

$$SubPbArrayRefIdxLXN[xPb + x][yPb + y] = spRefIdxLX[x / nSbW][y / nSbH] \quad (I-162)$$

$$SubPbArrayMvLXN[xPb + x][yPb + y] = spMvLX[x / nSbW][y / nSbH] \quad (I-163)$$
 - The derivation process for chroma motion vectors as specified in clause 8.5.3.2.10 is invoked with $SubPbArrayMvLXN[xPb + x][yPb + y]$ as input, and the output is $SubPbArrayMvCLXN[xPb + x][yPb + y]$.

I.8.5.3.2.10 Derivation process for motion vectors for an inter-view predicted merging candidate

Inputs to this process are:

- a luma location $(xBlk, yBlk)$ of the top-left sample of the current luma prediction block or sub-block partition relative to the top-left luma sample of the current picture,
- two variables $nBlkW$ and $nBlkH$ specifying the width and the height of the current luma prediction block or sub-block partition,
- a disparity vector offset $(xOff, yOff)$.

Outputs of this process are (with X in the range of 0 to 1, inclusive):

- the prediction utilization flag $predFlagLXInterView$,
- the reference index $refIdxLXInterView$,
- the motion vector $mvLXInterView$.

For X in the range of 0 to 1, inclusive, the flag $predFlagLXInterView$ is set equal to 0, the variable $refIdxLXInterView$ is set equal to -1 , and the motion vector $mvLXInterView$ is set equal to $(0, 0)$.

The luma location (xRef, yRef) is derived as follows:

$$\text{dispVec}[0] = \text{DispRefVec}[x_{\text{Blk}}][y_{\text{Blk}}][0] + x_{\text{Off}} \quad (\text{I-164})$$

$$\text{dispVec}[1] = \text{DispRefVec}[x_{\text{Blk}}][y_{\text{Blk}}][1] + y_{\text{Off}} \quad (\text{I-165})$$

$$x_{\text{RefFull}} = x_{\text{Blk}} + (n_{\text{BlkW}} \gg 1) + ((\text{dispVec}[0] + 2) \gg 2) \quad (\text{I-166})$$

$$y_{\text{RefFull}} = y_{\text{Blk}} + (n_{\text{BlkH}} \gg 1) + ((\text{dispVec}[1] + 2) \gg 2) \quad (\text{I-167})$$

$$x_{\text{Ref}} = \text{Clip3}(0, \text{pic_width_in_luma_samples} - 1, (x_{\text{RefFull}} \gg 3) \ll 3) \quad (\text{I-168})$$

$$y_{\text{Ref}} = \text{Clip3}(0, \text{pic_height_in_luma_samples} - 1, (y_{\text{RefFull}} \gg 3) \ll 3) \quad (\text{I-169})$$

Let ivRefPic the picture with nuh_layer_id equal to ViewCompLayerId[RefViewIdx[xBlk][yBlk]][DepthFlag] in the current access unit and let ivRefPb be the luma prediction block covering the luma location (xRef, yRef) in the picture ivRefPic.

The luma location (xIvRefPb, yIvRefPb) is set equal to the location of the top-left sample of ivRefPb relative to the top-left luma sample of the picture ivRefPic.

When ivRefPb is not coded in an intra prediction mode, the following applies for X in the range of 0 to (slice_type == B) ? 1 : 0, inclusive:

- For k in the range of 0 to 1, inclusive, the following applies:
 - Y is set equal to (k == 0) ? X : (1 – X).
 - The variables predFlagLYIvRef[x][y], mvLYIvRef[x][y], and refIdxLYIvRef[x][y] are set equal to PredFlagLY[x][y], MvLY[x][y], and RefIdxLY[x][y], respectively, of picture ivRefPic.
 - The variable refPicListYIvRef is set equal to RefPicListY of the slice containing ivRefPb in picture ivRefPic.
 - When predFlagLYIvRef[xIvRefPb][yIvRefPb] is equal to 1, the following applies for i in the range of 0 to num_ref_idx_LX_active_minus1, inclusive:
 - When PicOrderCnt(refPicListYIvRef[refIdxLYIvRef[xIvRefPb][yIvRefPb]]) is equal to PicOrderCnt(RefPicListX[i]) and predFlagLXInterView is equal to 0, the following applies:

$$\text{predFlagLXInterView} = 1 \quad (\text{I-170})$$

$$\text{refIdxLXInterView} = i \quad (\text{I-171})$$

$$\text{mvLXInterView} = \text{mvLYIvRef}[x_{\text{IvRefPb}}][y_{\text{IvRefPb}}] \quad (\text{I-172})$$

I.8.5.3.2.11 Derivation process for motion vectors for the texture merge candidate

Inputs to this process are:

- a luma location (xSb, ySb) of the top-left sample of the current luma sub-block partition relative to the top-left luma sample of the current picture,
- two variables nSbW and nSbH specifying the width and the height of the current sub-block partition,

Outputs of this process are (with X in the range of 0 to 1, inclusive):

- the prediction utilization flag predFlagLXT,
- the reference index refIdxLXT,
- the motion vector mvLXT.

For X in the range of 0 to 1, inclusive, the variable predFlagLXT is set equal to 0, the variable refIdxLXT is set equal to –1, and the motion vector mvLXT is set equal to (0, 0).

The texture luma location (xRef, yRef) is derived as follows:

$$x_{\text{RefFull}} = x_{\text{Sb}} + (n_{\text{SbW}} \gg 1) \quad (\text{I-173})$$

$$y_{\text{RefFull}} = y_{\text{Sb}} + (n_{\text{SbH}} \gg 1) \quad (\text{I-174})$$

$$x_{\text{Ref}} = (x_{\text{RefFull}} \gg 3) \ll 3 \quad (\text{I-175})$$

$$y_{\text{Ref}} = (y_{\text{RefFull}} \gg 3) \ll 3 \quad (\text{I-176})$$

Let textPb be the prediction block covering the luma sample location (xRef, yRef) in the picture TexturePic.

For X in the range of 0 to $(\text{slice_type} == B) ? 1 : 0$, inclusive, the following applies:

- The arrays $\text{textPredFlagLX}[x][y]$, $\text{textRefIdxLX}[x][y]$, and $\text{textMvLX}[x][y]$ are set equal to $\text{PredFlagLX}[x][y]$, $\text{RefIdxLX}[x][y]$, and $\text{MvLX}[x][y]$, respectively, of the picture TexturePic .
- The list textRefPicListX is set equal to RefPicListX of the slice containing textPb in the picture TexturePic .
- When $\text{textPredFlagLX}[\text{xRef}][\text{yRef}]$ is equal to 1, the following applies for i in the range of 0 to $\text{num_ref_idx_lX_active_minus1}$, inclusive:
 - When $\text{PicOrderCnt}(\text{RefPicListX}[i])$ is equal to $\text{PicOrderCnt}(\text{textRefPicListX}[\text{textRefIdxLX}])$, $\text{ViewIdx}(\text{RefPicListX}[i])$ is equal to $\text{ViewIdx}(\text{textRefPicListX}[\text{textRefIdxLX}])$, and predFlagLXT is equal to 0, the following applies:

$$\text{predFlagLXT} = 1 \quad (\text{I-177})$$

$$\text{refIdxLXT} = i \quad (\text{I-178})$$

$$\text{mvLXT}[0] = (\text{textMvLX}[\text{xRef}][\text{yRef}][0] + 2) \gg 2 \quad (\text{I-179})$$

$$\text{mvLXT}[1] = (\text{textMvLX}[\text{xRef}][\text{yRef}][1] + 2) \gg 2 \quad (\text{I-180})$$

1.8.5.3.2.12 Derivation process for disparity information merging candidates

Inputs to this process are:

- a luma location (xPb, yPb) of the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables nPbW and nPbH specifying the width and the height of the current prediction block.

Outputs of this process are (with X in the range of 0 to 1, inclusive):

- the flags availableFlagDI and $\text{availableFlagDIShift}$, specifying whether the disparity information merging candidate and the shifted disparity information candidate are available,
- the prediction list utilization flags predFlagLXDI and predFlagLXDISHift ,
- the reference indices refIdxLXDI and refIdxLXDISHift ,
- the motion vectors mvLXDI and mvLXDISHift .

The variables availableFlagDI and $\text{availableFlagDIShift}$ are set equal to 0, and for X in the range of 0 to 1, inclusive, the following applies:

- The variables predFlagLXDI and predFlagLXDISHift are set equal to 0, the variables refIdxLXDI and refIdxLXDISHift are set equal to -1, and the motion vectors mvLXDI and mvLXDISHift are set equal to $(0, 0)$.

The disparity information merging candidate is derived as follows:

- For X in the range of 0 to $(\text{slice_type} == B) ? 1 : 0$, inclusive, the following applies:
 - For i in the range of 0 to $\text{num_ref_idx_lX_active_minus1}$, inclusive, the following applies:
 - When $\text{PicOrderCnt}(\text{RefPicListX}[i])$ is equal to the PicOrderCntVal , $\text{ViewIdx}(\text{RefPicListX}[i])$ is equal to $\text{RefViewIdx}[\text{xPb}][\text{yPb}]$, and predFlagLXDI is equal to 0, the following applies:

$$\text{availableFlagDI} = 1 \quad (\text{I-181})$$

$$\text{predFlagLXDI} = 1 \quad (\text{I-182})$$

$$\text{refIdxLXDI} = i \quad (\text{I-183})$$

$$\text{mvLXDI} = (\text{DispRefVec}[\text{xPb}][\text{yPb}][0], 0) \quad (\text{I-184})$$

When availableFlagDI is equal to 1, the shifted disparity information merging candidate is derived as follows:

- The variable $\text{availableFlagDIShift}$ is set equal to 1.
- The following applies for X in the range of 0 to 1, inclusive:

$$\text{predFlagLXDISHift} = \text{predFlagLXDI} \quad (\text{I-185})$$

$$\text{refIdxLXDISHift} = \text{refIdxLXDI} \quad (\text{I-186})$$

$$\text{mvLXDISHift} = \text{predFlagLXDI} ? (\text{mvLXDI}[0] + 4, \text{mvLXDI}[1]) : (0, 0) \quad (\text{I-187})$$

I.8.5.3.2.13 Derivation process for a view synthesis prediction merging candidate

Inputs to this process are:

- a luma location (xPb, yPb) of the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables $nPbW$ and $nPbH$ specifying the width and the height of the current prediction block.

Outputs of this process are (with X in the range of 0 to 1, inclusive):

- the availability flag $availableFlagVSP$ specifying whether the view synthesis prediction merging candidate is available,
- the prediction list utilization flag $predFlagLXVSP$,
- the reference index $refIdxLXVSP$,
- the motion vector $mvLXVSP$.

The variable $availableFlagVSP$ is set equal to 0 and for X in the range of 0 to 1, inclusive, the following applies:

- The variable $predFlagLXVSP$ is set equal to 0, the variable $refIdxLXVSP$ is set equal to -1 , and the motion vector $mvLXVSP$ is set equal to (0, 0).

For X in the range of 0 to ($slice_type == B ? 1 : 0$), inclusive, the following applies:

- For i in the range of 0 to $num_ref_idx_IX_active_minus1$, inclusive, the following applies:
 - When $availableFlagVSP$ is equal to 0 and $ViewIdx(RefPicListX[i])$ is equal to $RefViewIdx[xPb][yPb]$, the following applies:

$$availableFlagVSP = 1 \quad (I-188)$$

$$predFlagLXVSP = 1 \quad (I-189)$$

$$refIdxLXVSP = i \quad (I-190)$$

$$mvLXVSP = DispVec[xPb][yPb] \quad (I-191)$$

When $availableFlagVSP$ is equal to 1 the following applies:

- The derivation process for a depth or disparity sample array from a depth picture as specified in clause I.8.5.7 is invoked with the luma location (xPb, yPb), the variables $nPbW$ and $nPbH$, the disparity vector $DispVec[xPb][yPb]$, the reference view order index $RefViewIdx[xPb][yPb]$, and the variable $partIdx$ equal to 2 as inputs, and the outputs are the array $disparitySamples$ of size $(nPbW) \times (nPbH)$, and the flag $horSplitFlag$.
- For use in derivation processes of variables invoked later in the decoding process, the following assignments are made for $x = 0..nPbW - 1$ and $y = 0..nPbH - 1$:

- The variable $SubPbArrayPartSizeVSP[xPb + x][yPb + y]$ is set equal to ($horSplitFlag ? (8, 4) : (4, 8)$).

- For X in the range of 0 to 1, inclusive, the following applies:

- The variables $SubPbArrayPredFlagLXVSP$, $SubPbArrayMvLXVSP$, and $SubPbArrayRefIdxLXVSP$ are derived as follows:

$$SubPbArrayPredFlagLXVSP[xPb + x][yPb + y] = predFlagLXVSP \quad (I-192)$$

$$SubPbArrayRefIdxLXVSP[xPb + x][yPb + y] = refIdxLXVSP \quad (I-193)$$

$$SubPbArrayMvLXVSP[xPb + x][yPb + y] = predFlagLXVSP ? (disparitySamples[x][y], 0) : (0, 0) \quad (I-194)$$

- When $ChromaArrayType$ is not equal to 0, the derivation process for chroma motion vectors as specified in clause 8.5.3.2.9 is invoked with $SubPbArrayMvLXVSP[xPb + x][yPb + y]$ as input, and the output is $SubPbArrayMvCLXVSP[xPb + x][yPb + y]$.

I.8.5.3.3 Decoding process for inter prediction samples

I.8.5.3.3.1 General

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,

- a luma location (xBl , yBl) specifying the top-left sample of the current luma prediction block relative to the top-left sample of the current luma coding block,
- a variable $nCbS$ specifying the size of the current luma coding block,
- two variables $nPbW$ and $nPbH$ specifying the width and the height of the luma prediction block,
- the luma motion vectors $mvL0$ and $mvL1$,
- when $ChromaArrayType$ is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$,
- the reference indices $refIdxL0$ and $refIdxL1$,
- the prediction list utilization flags, $predFlagL0$ and $predFlagL1$.

Outputs of this process are:

- an $(nCbS_L) \times (nCbS_L)$ array $predSamples_L$ of luma prediction samples, where $nCbS_L$ is derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $predSamples_{Cb}$ of chroma prediction samples for the component Cb , where $nCbSw_C$ and $nCbSh_C$ are derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $predSamples_{Cr}$ of chroma prediction samples for the component Cr , where $nCbSw_C$ and $nCbSh_C$ are derived as specified below.

When $DepthFlag$ is equal to 1, the following applies, for X in the range of 0 to 1, inclusive:

- The variable $mvLX$ is set equal to ($mvLX \ll 2$).
- When $ChromaArrayType$ is not equal to 0, the variable $mvCLX$ is set equal to ($mvCLX \ll 2$).

The variable $nCbS_L$ is set equal to $nCbS$. When $ChromaArrayType$ is not equal to 0, the variable $nCbSw_C$ is set equal to $nCbS / SubWidthC$ and the variable $nCbSh_C$ is set equal to $nCbS / SubHeightC$.

1. Let $predSamplesL0_L$ and $predSamplesL1_L$ be $(nPbW) \times (nPbH)$ arrays of predicted luma sample values and, when $ChromaArrayType$ is not equal to 0, $predSamplesL0_{Cb}$, $predSamplesL1_{Cb}$, $predSamplesL0_{Cr}$, and $predSamplesL1_{Cr}$ be $(nPbW / SubWidthC) \times (nPbH / SubHeightC)$ arrays of predicted chroma sample values.
2. For X in the range of 0 to 1, inclusive, when $predFlagLX$ is equal to 1, the following applies:
 - When $predFlagLX$ is equal to 1, the following applies:
 - If $iv_res_pred_weight_idx[xCb][yCb]$ is not equal to 0, the bilinear sample interpolation and residual prediction process as specified in clause I.8.5.3.3.3 is invoked with the luma locations (xCb , yCb), (xBl , yBl), the size of the current luma coding block $nCbS$, the width and the height of the current luma prediction block $nPbW$ and $nPbH$, the prediction list utilization flags $predFlagL0$ and $predFlagL1$, the reference indices $refIdxL0$ and $refIdxL1$, the motion vectors $mvL0$ and $mvL1$, when $ChromaArrayType$ is not equal to 0, the motion vectors $mvCL0$ and $mvCL1$, and the prediction list indication X as inputs, and the array $predSamplesLX_L$ and, when $ChromaArrayType$ is not equal to 0, the arrays $predSamplesLX_{Cb}$ and $predSamplesLX_{Cr}$, as outputs.
 - Otherwise ($iv_res_pred_weight_idx[xCb][yCb]$ is equal to 0), the following applies:
 - The reference picture consisting of an ordered two-dimensional array $refPicLX_L$ of luma samples and, when $ChromaArrayType$ is not equal to 0, two ordered two-dimensional arrays $refPicLX_{Cb}$ and $refPicLX_{Cr}$ of chroma samples is derived by invoking the process specified in clause 8.5.3.3.2 with $refIdxLX$ as input.
 - The array $predSamplesLX_L$ and, when $ChromaArrayType$ is not equal to 0, the arrays $predSamplesLX_{Cb}$ and $predSamplesLX_{Cr}$ are derived by invoking the fractional sample interpolation process specified in clause 8.5.3.3.3 with the luma locations (xCb , yCb) and (xBl , yBl), the luma prediction block width $nPbW$, the luma prediction block height $nPbH$, the motion vectors $mvLX$ and, when $ChromaArrayType$ is not equal to 0, $mvCLX$, and the reference arrays $refPicLX_L$, $refPicLX_{Cb}$, and $refPicLX_{Cr}$ as inputs.
3. Depending on the value of $IlluCompFlag[xCb][yCb]$, the array $predSamples_L$ is derived as follows:
 - If $IlluCompFlag[xCb][yCb]$ is equal to 0, the following applies:
 - The prediction samples inside the current luma prediction block, $predSamples_L[x_L + xBl][y_L + yBl]$ with $x_L = 0..nPbW - 1$ and $y_L = 0..nPbH - 1$, are derived by invoking the weighted sample prediction process specified in clause 8.5.3.3.4 with the prediction block width $nPbW$, the prediction block height $nPbH$, and the sample arrays $predSamplesL0_L$ and $predSamplesL1_L$, and the variables $predFlagL0$, $predFlagL1$, $refIdxL0$, $refIdxL1$, and $cIdx$ equal to 0 as inputs.

- Otherwise ($\text{IlluCompFlag}[x_{Cb}][y_{Cb}]$ is equal to 1), the following applies:
 - The prediction samples inside the current luma prediction block, $\text{predSamples}_L[x_L + x_{Bl}][y_L + y_{Bl}]$ with $x_L = 0..n_{PbW} - 1$ and $y_L = 0..n_{PbH} - 1$, are derived by invoking the illumination compensated sample prediction process specified in clause I.8.5.3.3.2, with the luma location (x_{Cb}, y_{Cb}), the size of the current luma coding block n_{CbS} , the luma location (x_{Bl}, y_{Bl}), the width and the height of the current luma prediction block n_{PbW} and n_{PbH} , the sample arrays $\text{predSamples}_{L0_L}$ and $\text{predSamples}_{L1_L}$, the variables predFlag_{L0} , predFlag_{L1} , refIdx_{L0} , refIdx_{L1} , mv_{L0} , mv_{L1} and $cIdx$ equal to 0 as inputs.
- 4. When ChromaArrayType is not equal to 0, depending on the values of $\text{IlluCompFlag}[x_{Cb}][y_{Cb}]$ and n_{PbW} , the arrays predSamples_{Cb} , and predSamples_{Cr} are derived as follows:
 - If $\text{IlluCompFlag}[x_{Cb}][y_{Cb}]$ is equal to 0 or n_{PbW} is less than or equal to 8, the following applies:
 - The prediction samples inside the current chroma component Cb prediction block, $\text{predSamples}_{Cb}[x_C + x_{Bl} / \text{SubWidthC}][y_C + y_{Bl} / \text{SubHeightC}]$ with $x_C = 0..n_{PbW} / \text{SubWidthC} - 1$ and $y_C = 0..n_{PbH} / \text{SubHeightC} - 1$, are derived by invoking the weighted sample prediction process specified in clause 8.5.3.3.4 with the prediction block width n_{PbW} set equal to $n_{PbW} / \text{SubWidthC}$, the prediction block height n_{PbH} set equal to $n_{PbH} / \text{SubHeightC}$, the sample arrays $\text{predSamples}_{L0_{Cb}}$ and $\text{predSamples}_{L1_{Cb}}$, and the variables predFlag_{L0} , predFlag_{L1} , refIdx_{L0} , refIdx_{L1} , and $cIdx$ equal to 1 as inputs.
 - The prediction samples inside the current chroma component Cr prediction block, $\text{predSamples}_{Cr}[x_C + x_{Bl} / \text{SubWidthC}][y_C + y_{Bl} / \text{SubHeightC}]$ with $x_C = 0..n_{PbW} / \text{SubWidthC} - 1$ and $y_C = 0..n_{PbH} / \text{SubHeightC} - 1$, are derived by invoking the weighted sample prediction process specified in clause 8.5.3.3.4 with the prediction block width n_{PbW} set equal to $n_{PbW} / \text{SubWidthC}$, the prediction block height n_{PbH} set equal to $n_{PbH} / \text{SubHeightC}$, the sample arrays $\text{predSamples}_{L0_{Cr}}$ and $\text{predSamples}_{L1_{Cr}}$, and the variables predFlag_{L0} , predFlag_{L1} , refIdx_{L0} , refIdx_{L1} , and $cIdx$ equal to 2 as inputs.
 - Otherwise ($\text{IlluCompFlag}[x_{Cb}][y_{Cb}]$ is equal to 1 and n_{PbW} is greater than 8), the following applies:
 - The prediction samples inside the current chroma component Cb prediction block, $\text{predSamples}_{Cb}[x_C + x_{Bl} / \text{SubWidthC}][y_C + y_{Bl} / \text{SubHeightC}]$ with $x_C = 0..n_{PbW} / \text{SubWidthC} - 1$ and $y_C = 0..n_{PbH} / \text{SubHeightC} - 1$, are derived by invoking the illumination compensated sample prediction process specified in clause I.8.5.3.3.2, with the luma location (x_{Cb}, y_{Cb}), the size of the current luma coding block n_{CbS} , the chroma location ($x_{Bl} / \text{SubWidthC}, y_{Bl} / \text{SubHeightC}$), the width and the height of the current chroma prediction block ($n_{PbW} / \text{SubWidthC}$) and ($n_{PbH} / \text{SubHeightC}$), the sample arrays $\text{predSamples}_{L0_{Cb}}$ and $\text{predSamples}_{L1_{Cb}}$, the variables predFlag_{L0} , predFlag_{L1} , refIdx_{L0} , refIdx_{L1} , mv_{CL0} , mv_{CL1} , and $cIdx$ equal to 1 as inputs.
 - The prediction samples inside the current chroma component Cr prediction block, $\text{predSamples}_{Cr}[x_C + x_{Bl} / \text{SubWidthC}][y_C + y_{Bl} / \text{SubHeightC}]$ with $x_C = 0..n_{PbW} / \text{SubWidthC} - 1$ and $y_C = 0..n_{PbH} / \text{SubHeightC} - 1$, are derived by invoking the illumination compensated sample prediction process specified in clause I.8.5.3.3.2, with the luma location (x_{Cb}, y_{Cb}), the size of the current luma coding block n_{CbS} , the chroma location ($x_{Bl} / \text{SubWidthC}, y_{Bl} / \text{SubHeightC}$), the width and the height of the current chroma prediction block ($n_{PbW} / \text{SubWidthC}$) and ($n_{PbH} / \text{SubHeightC}$), the sample arrays $\text{predSamples}_{L0_{Cr}}$ and $\text{predSamples}_{L1_{Cr}}$, the variables predFlag_{L0} , predFlag_{L1} , refIdx_{L0} , refIdx_{L1} , mv_{CL0} , mv_{CL1} , and $cIdx$ equal to 2 as inputs.

I.8.5.3.3.2 Illumination compensated sample prediction process

I.8.5.3.3.2.1 General

Inputs to this process are:

- a location (x_{Cb}, y_{Cb}) specifying the top-left sample of the current luma coding block relative to the top-left sample of the current picture,
- the size of current luma coding block n_{CbS} ,
- a location (x_{Bl}, y_{Bl}) specifying the top-left sample of the current luma or chroma prediction block relative to the top-left sample of the current luma coding block,
- two variables n_{PbW} and n_{PbH} specifying the width and height of the current luma or chroma prediction block,
- two $(n_{PbW} \times n_{PbH})$ arrays predSamples_{L0} and predSamples_{L1} ,
- two prediction list utilization flags predFlag_{L0} and predFlag_{L1} ,

- two reference indices refIdxL0 and refIdxL1,
- two motion vector mvL0 and mvL1,
- a colour component index cIdx.

Output of this process is an (nPbW)x(nPbH) array predSamples of prediction sample values.

The variables bitDepth, shift1, shift2, offset1, and offset2 are derived as follows:

$$\text{bitDepth} = (\text{cIdx} == 0) ? \text{BitDepth}_Y : \text{BitDepth}_C \quad (\text{I-195})$$

$$\text{shift1} = \text{Max}(2, 14 - \text{bitDepth}) \quad (\text{I-196})$$

$$\text{shift2} = \text{Max}(3, 15 - \text{bitDepth}) \quad (\text{I-197})$$

$$\text{offset1} = 1 \ll (\text{shift1} - 1) \quad (\text{I-198})$$

$$\text{offset2} = 1 \ll (\text{shift2} - 1) \quad (\text{I-199})$$

The derivation process for illumination compensation mode availability and parameters as specified in clause I.8.5.3.3.2.2 is invoked with the luma location (xCb, yCb), the size of the current luma coding block nCbS, the prediction list utilization flags predFlagL0 and predFlagL1, the reference indices refIdxL0 and refIdxL1, the motion vectors mvL0 and mvL1, the variable bitDepth, and the variable cIdx as inputs, and the outputs are the flags puIcFlagL0 and puIcFlagL1, the variables icWeightL0 and icWeightL1, and the variables icOffsetL0 and icOffsetL1.

Depending on the value of predFlagL0 and predFlagL1, the prediction samples predSamples[x][y] with $x = 0..(\text{nPbW} - 1)$ and $y = 0..(\text{nPbH} - 1)$ are derived as follows:

- For X in the range of 0 to 1, inclusive, the following applies:

- When predFlagLX is equal to 1, the following applies:

$$\text{clipPredVal} = \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, (\text{predSamplesLX}[x][y] + \text{offset1}) \gg \text{shift1}) \quad (\text{I-200})$$

$$\begin{aligned} \text{predValX} &= !\text{puIcFlagLX} ? \text{clipPredVal} : \\ &(\text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, (\text{clipPredVal} * \text{icWeightLX}) \gg 5) + \text{icOffsetLX}) \end{aligned} \quad (\text{I-201})$$

- If predFlagL0 and predFlagL1 are equal to 1, the following applies:

$$\text{predSamples}[x][y] = \text{Clip3}(0, (1 \ll \text{bitDepth}) - 1, (\text{predVal0} + \text{predVal1} + \text{offset2}) \gg \text{shift2}) \quad (\text{I-202})$$

- Otherwise (predFlagL0 is equal to 0 or predFlagL1 is equal to 0), the following applies:

$$\text{predSamples}[x][y] = \text{predFlagL0} ? \text{predVal0} : \text{predVal1} \quad (\text{I-203})$$

I.8.5.3.3.2.2 Derivation process for illumination compensation mode availability and parameters

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- the size of the current luma coding block nCbS,
- two prediction list utilization flags predFlagL0 and predFlagL1,
- two reference indices refIdxL0 and refIdxL1,
- two motion vectors mvL0 and mvL1,
- a bit depth of samples bitDepth,
- a variable cIdx specifying colour component index.

Outputs of this process are:

- the flags puIcFlagL0 and puIcFlagL1 specifying whether illumination compensation is enabled,
- the variables icWeightL0 and icWeightL1 specifying weights for illumination compensation,
- the variables icOffsetL0 and icOffsetL1 specifying offsets for illumination compensation.

The variables puIcFlagL0 and puIcFlagL1 are set equal to 0, the variables icWeightL0 and icWeightL1 are set equal to 1, and the variables icOffsetL0 and icOffsetL1 are set equal to 0.

The variables subWidth, subHeight, and the location (xC, yC) specifying the top-left sample of the current luma or chroma

coding block are derived as follows:

$$\text{subWidth} = (\text{cIdx} == 0) ? 1 : \text{SubWidthC} \quad (\text{I-204})$$

$$\text{subHeight} = (\text{cIdx} == 0) ? 1 : \text{SubHeightC} \quad (\text{I-205})$$

$$(\text{xC}, \text{yC}) = (\text{xCb} / \text{subWidth}, \text{yCb} / \text{subHeight}) \quad (\text{I-206})$$

The variable `availFlagCurAboveRow` specifying the availability of above neighbouring row samples is derived by invoking the availability derivation process for a block in z-scan order as specified in clause 6.4.1 with the location $(\text{xCurr}, \text{yCurr})$ set equal to (xCb, yCb) and the neighbouring location (xN, yN) set equal to $(\text{xCb}, \text{yCb} - 1)$ as inputs, and the output is assigned to `availFlagCurAboveRow`.

The variable `availFlagCurLeftCol` specifying the availability of left neighbouring column samples is derived by invoking the availability derivation process for a block in z-scan order as specified in clause 6.4.1 with the location $(\text{xCurr}, \text{yCurr})$ set equal to (xCb, yCb) and the neighbouring location (xN, yN) set equal to $(\text{xCb} - 1, \text{yCb})$ as inputs, and the output is assigned to `availFlagCurLeftCol`.

When `availFlagCurAboveRow` is equal to 1 or `availFlagCurLeftCol` is equal to 1, the following applies:

1. Depending on the value of `cIdx`, the variable `curRecSamples` specifying the reconstructed picture samples before deblocking filter of the current picture is derived as follows:

$$\text{curRecSamples} = (\text{cIdx} == 0) ? S_L : ((\text{cIdx} == 1) ? S_{Cb} : S_{Cr}) \quad (\text{I-207})$$

2. For X in the range of 0 to 1, inclusive, when `predFlagLX` is equal to 1, the following applies:

- Let `refPicLX` be the picture `RefPicListX[refIdxLX]`.
- When `ViewIdx(refPicLX)` is not equal to `ViewIdx`, the following applies:
 - The variable `puIcFlagLX` is set equal to 1.
 - The luma location $(\text{xRefBlkLX}, \text{yRefBlkLX})$ specifying the top-left sample of the reference block in the picture `refPicLX` is derived as follows:

$$\text{xRefBlkLX} = \text{xC} + ((\text{mvLX}[0] + (\text{cIdx} ? 4 : 2)) \gg (2 + (\text{cIdx} ? 1 : 0))) \quad (\text{I-208})$$

$$\text{yRefBlkLX} = \text{yC} + ((\text{mvLX}[1] + (\text{cIdx} ? 4 : 2)) \gg (2 + (\text{cIdx} ? 1 : 0))) \quad (\text{I-209})$$

- Depending on the value of `cIdx`, the variable `refRecSamplesLX` specifying the reconstructed picture samples of the picture `refPicLX` is derived as follows:
 - If `cIdx` is equal to 0, `refRecSamplesLX` is set equal to reconstructed picture sample array S_L of picture `refPicLX`.
 - Otherwise, if `cIdx` is equal to 1, `refRecSamplesLX` is set equal to the reconstructed chroma sample array S_{Cb} of picture `refPicLX`.
 - Otherwise (`cIdx` is equal to 2), `refRecSamplesLX` is set equal to the reconstructed chroma sample array S_{Cr} of picture `refPicLX`.
3. The lists `curSampleList`, `refSampleList0`, and `refSampleList1`, specifying the neighbouring samples in pictures `CurrPic`, `refPicL0`, and `refPicL1`, respectively, are derived as follows:
 - The variable `numSamples` specifying the number of elements of `curSampleList`, `refSampleList0`, and `refSampleList1` is set equal to 0.
 - For `curNbColFlag` in the range of 0 to 1, inclusive, the following applies:
 - When $(\text{curNbColFlag} ? \text{availFlagCurLeftCol} : \text{availFlagCurAboveRow})$ is equal to 1, the following applies, for i in the range of 0 to $(\text{nCbS} / (\text{curNbColFlag} ? \text{subHeight} : \text{subWidth})) - 1$, inclusive:
 - The variables `xOff` and `yOff` are derived as follows:

$$\text{xOff} = \text{curNbColFlag} ? -1 : i \quad (\text{I-210})$$

$$\text{yOff} = \text{curNbColFlag} ? i : -1 \quad (\text{I-211})$$

- For X in the range of 0 to 1, inclusive, when `puIcFlagLX` is equal to 1, the following applies:

$$\text{xP} = \text{Clip3}(0, (\text{pic_width_in_luma_samples} / \text{subWidth}) - 1, \text{xRefBlkLX} + \text{xOff}) \quad (\text{I-212})$$

$$\text{yP} = \text{Clip3}(0, (\text{pic_height_in_luma_samples} / \text{subHeight}) - 1, \text{yRefBlkLX} + \text{yOff}) \quad (\text{I-213})$$

$$\text{refSampleListLX}[\text{numSamples}] = \text{refRecSamplesLX}[\text{xP}][\text{yP}] \quad (\text{I-214})$$

- The variables `curSampleList` and `numSamples` are modified as follows:

$$\text{curSampleList}[\text{numSamples}++] = \text{curRecSamples}[\text{xC} + \text{xOff}][\text{yC} + \text{yOff}] \quad (\text{I-215})$$

4. For X in the range of 0 to 1, inclusive, when `puIcFlagLX` is equal to 1, `icWeightLX` and `icOffsetLX` are modified as follows:
 - The derivation process for illumination compensation parameters as specified in clause I.8.5.3.3.2.3 is invoked, with the list of neighbouring samples in the current picture `curSampleList`, the list of neighbouring samples in the reference picture `refSampleListX`, the number of neighbouring samples `numSamples`, the variable `bitDepth`, and the variable `cIdx` as inputs, and the variables `icWeightLX` and `icOffsetLX` as outputs.

I.8.5.3.3.2.3 Derivation process for illumination compensation parameters

Inputs to this process are:

- a list `curSampleList` specifying the current neighbouring samples,
- a list `refSampleList` specifying the reference neighbouring samples,
- a variable `numSamples` specifying the number of elements of `curSampleList` and `refSampleList`,
- a variable `bitDepth` specifying the bit depth of samples,
- a variable `cIdx` specifying colour component index.

Outputs of this process are:

- the variable `icWeight` specifying a weight for illumination compensation,
- the variable `icOffset` specifying an offset for illumination compensation.

The variable `precShift` is set equal to $\text{Max}(0, \text{bitDepth} - 12)$.

The variables `sumRef` and `sumCur` are set equal to 0 and the following applies for i in the range of 0 to $(\text{numSamples} / 2 - 1)$, inclusive:

$$\text{sumRef} += \text{refSampleList}[2 * i] \quad (\text{I-216})$$

$$\text{sumCur} += \text{curSampleList}[2 * i] \quad (\text{I-217})$$

The variables `avgShift` and `avgOffset` are derived as follows:

$$\text{avgShift} = \text{Log2}(\text{numSamples} / 2) \quad (\text{I-218})$$

$$\text{avgOffset} = 1 \ll (\text{avgShift} - 1) \quad (\text{I-219})$$

Depending on the value of `cIdx`, the variables `icWeight` and `icOffset` are derived as follows:

- If `cIdx` is equal to 0, the following applies:
 - The variables `sumRefSquare` and `sumProdRefCur` are set equal to 0, and the following applies for i in the range of 0 to $(\text{numSamples} / 2 - 1)$, inclusive:

$$\text{sumRefSquare} += (\text{refSampleList}[2 * i] * \text{refSampleList}[2 * i]) \gg \text{precShift} \quad (\text{I-220})$$

$$\text{sumProdRefCur} += (\text{refSampleList}[2 * i] * \text{curSampleList}[2 * i]) \gg \text{precShift} \quad (\text{I-221})$$
 - The variables `numerDiv` and `denomDiv` are derived as follows:

$$\text{denomDiv} = ((\text{sumRefSquare} + (\text{sumRefSquare} \gg 7)) \ll \text{avgShift}) - ((\text{sumRef} * \text{sumRef}) \gg \text{precShift}) \quad (\text{I-222})$$

$$\text{numerDiv} = \text{Clip3}(0, 2 * \text{denomDiv}, ((\text{sumProdRefCur} + (\text{sumRefSquare} \gg 7)) \ll \text{avgShift}) - ((\text{sumRef} * \text{sumCur}) \gg \text{precShift})) \quad (\text{I-223})$$
 - The variables `shiftNumer` and `shiftDenom` are derived as follows:

$$\text{shiftDenom} = \text{Max}(0, \text{Floor}(\text{Log2}(\text{Abs}(\text{denomDiv}))) - 5) \quad (\text{I-224})$$

$$\text{shiftNumer} = \text{Max}(0, \text{shiftDenom} - 12) \quad (\text{I-225})$$
 - The variables `sNumerDiv` and `sDenomDiv` are derived as follows:

$$\text{sDenomDiv} = \text{denomDiv} \gg \text{shiftDenom} \quad (\text{I-226})$$

$$sNumerDiv = numerDiv \gg shiftNumer \quad (I-227)$$

- The value of variable divCoeff is derived from Table I.3 depending on the value of sDenomDiv, and the variables icWeight and icOffset are derived as follows:

$$icWeight = (sNumerDiv * divCoeff) \gg (shiftDenom - shiftNumer + 10) \quad (I-228)$$

$$icOffset = (sumCur - ((icWeight * sumRef) \gg 5) + avgOffset) \gg avgShift \quad (I-229)$$

- Otherwise (cIdx is not equal to 0), the following applies:

$$icWeight = 32 \quad (I-230)$$

$$icOffset = (sumCur - sumRef + avgOffset) \gg avgShift \quad (I-231)$$

Table I.3 – Specification of divCoeff depending on sDenomDiv

I.8.5.3.3.3 Bilinear sample interpolation and residual prediction process

I.8.5.3.3.3.1 General

The process is only invoked when iv_res_pred_weight_idx[xCb][yCb] is not equal to 0.

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (xBl, yBl) specifying the top-left sample of the current luma prediction block relative to the top-left sample of the current luma coding block,
- a variable nCbS specifying the size of the current luma coding block,
- two variables nPbW and nPbH specifying the width and the height of the current luma prediction block,
- two prediction list utilization flags predFlagL0 and predFlagL1,
- two reference indices refIdxL0 and refIdxL1,
- two motion vectors mvL0 and mvL1,
- when ChromaArrayType is not equal to 0, two motion vectors mvCL0 and mvCL1,
- a prediction list indication X.

Outputs of this process are:

- the (nPbW)x(nPbH) array predSamplesLXL,
- when ChromaArrayType is not equal to 0, the (nPbW / SubWidthC)x(nPbH / SubHeightC) arrays predSamplesLXCb and predSamplesLXCcr.

The location (xPb, yPb) is derived as follows:

$$xPb = xCb + xBl \quad (I-232)$$

$$yPb = yCb + yBl \quad (I-233)$$

The prediction list indication variable Y is set equal to (1 - X) and the variable availFlag is set equal to 0.

The variable `ivRefFlagLX` is set equal to $(\text{DiffPicOrderCnt}(\text{CurrPic}, \text{RefPicListX}[\text{refIdxLX}]) == 0)$ and the variable `ivRefFlagLY` is set equal to $\text{predFlagLY} ? (\text{DiffPicOrderCnt}(\text{CurrPic}, \text{RefPicListY}[\text{refIdxLY}]) == 0) : 0$.

Depending on the values of `ivRefFlagLX`, `ivRefFlagLY`, and `RpRefIdxLX`, the following applies:

- If `ivRefFlagLX` is equal to 0, the variable `availFlag` is set equal to 1, the variable `refIdxLX` is set equal to `RpRefIdxLX`, and the residual prediction motion vector scaling process as specified in clause I.8.5.3.3.3.4 is invoked with the prediction list indication variable equal to X, the motion vector `mvLX`, and the picture `RefPicListX[refIdxLX]` as inputs, and the modified motion vector `mvLX` as output.
- Otherwise (when `ivRefFlagLX` is equal to 1), the following applies:
 - If `predFlagLY` is equal to 1 and `ivRefFlagLY` is equal to 0, the following applies:
 - The variable `availFlag` is set equal to 1.
 - The residual prediction motion vector scaling process as specified in clause I.8.5.3.3.3.4 is invoked with the prediction list indication variable equal to Y, the motion vector `mvLY`, and the picture `RefPicListY[refIdxLY]` as inputs, and the modified motion vector `mvLY` as output.
 - The motion vector `mvT` is set equal to `mvLY` and the prediction list indication variable Z is set equal to Y.
 - Otherwise (`predFlagLY` is equal to 0 or `ivRefFlagLY` is equal to 1), the following applies:
 - The variable W is set equal to $(\text{predFlagLY} \ \&\& \ \text{ivRefFlagLY}) ? 0 : X$.
 - The derivation process for a motion vector from a reference block for residual prediction as specified in clause I.8.5.3.3.3.5 is invoked with the luma location (xPb, yPb) , the variables `nPbW` and `nPbH`, the picture `RefPicListW[refIdxLW]`, and the motion vector `mvLW` as inputs, and the flag `availFlag`, the motion vector `mvT`, and the prediction list utilization variable Z as outputs.
 - When `availFlag` is equal to 0 and `RpRefPicAvailFlagLW` is equal to 1, `availFlag` is set equal to 1, `mvT` is set equal to $(0, 0)$, and Z is set equal to W.

When `ChromaArrayType` is not equal to 0, the derivation process for chroma motion vectors in clause 8.5.3.2.10 is invoked with `mvLX` as input, and the output being `mvCLX`.

The array `predSamplesLXL`, and, when `ChromaArrayType` is not equal to 0, the arrays `predSamplesLXCb` and `predSamplesLXCr` are derived as follows:

- The reference picture consisting of an ordered two-dimensional array `refPicLXL` of luma samples and, when `ChromaArrayType` is not equal to 0, two ordered two-dimensional arrays `refPicLXCb` and `refPicLXCr` of chroma samples, are derived by invoking the reference picture selection process as specified in clause 8.5.3.3.2 with `refIdxLX` as input.
- The array `predSamplesLXL` and, when `ChromaArrayType` is not equal to 0, the arrays `predSamplesLXCb` and `predSamplesLXCr`, are derived by invoking the bilinear sample interpolation process specified in clause I.8.5.3.3.3.2 with the luma locations (xCb, yCb) and (xBl, yBl) , the luma prediction block width `nPbW`, the luma prediction block height `nPbH`, the motion vector `mvLX`, and, when `ChromaArrayType` is not equal to 0, the motion vector `mvCLX`, the reference array `refPicLXL` and, when `ChromaArrayType` is not equal to 0, the arrays `refPicLXCb` and `refPicLXCr` as inputs.

When one of the following conditions is true, `availFlag` is set equal to 0:

- `ivRefFlagLX` is equal to 0 and `RefRpRefAvailFlagLX[RefViewIdx[xPb][yPb]]` is equal to 0.
- `ivRefFlagLX` is equal to 1 and `RefRpRefAvailFlagLZ[ViewIdx(RefPicListX[refIdxLX])]` is equal to 0.

When `availFlag` is equal to 1, the following applies:

- Depending on the value of `ivRefFlagLX`, the variables `rpPic`, `rpRefPic`, and `mvRp` are derived as follows:
 - If `ivRefFlagLX` is equal to 0, the following applies:
 - Let `rpPic` be the picture with `PicOrderCnt(rpPic)` equal to `PicOrderCntVal` and `nuh_layer_id` equal to `ViewCompLayerId[RefViewIdx[xPb][yPb]][DepthFlag]`.
 - Let `rpRefPic` be the picture with `PicOrderCnt(rpRefPic)` equal to `PicOrderCnt(RefPicListX[RpRefIdxLX])` and `nuh_layer_id` equal to `ViewCompLayerId[RefViewIdx[xPb][yPb]][DepthFlag]`.
 - The variable `mvRp` is set equal to `DispVec[xPb][yPb]`.

- Otherwise (ivRefFlagLX is equal to 1), the following applies:
 - Let rpPic be the picture RefPicListZ[RpRefIdxLZ].
 - Let rpRefPic be the picture with PicOrderCnt(rpRefPic) equal to PicOrderCnt(rpPic) and nuh_layer_id equal to ViewCompLayerId[ViewIdx(RefPicListX[refIdxLX])][DepthFlag].
 - The variable mvRp is set equal to mvT.
- When ChromaArrayType is not equal to 0, the derivation process for chroma motion vectors in clause 8.5.3.2.10 is invoked with mvRp as input, and the output being mvRpC.
- The array rpSamplesLXL and, when ChromaArrayType is not equal to 0, the arrays rpSamplesLXCb and rpSamplesLXCcr are derived as follows:
 - Let the reference sample array rpPicLXL correspond to the decoded sample array SL derived in clause 8.7 for the previously decoded picture rpPic.
 - When ChromaArrayType is not equal to 0, let the reference sample arrays rpPicLXCb and rpPicLXCcr correspond to the decoded sample arrays SCb and SCr, respectively, derived in clause 8.7 for the previously decoded picture rpPic.
 - The array rpSamplesLXL and, when ChromaArrayType is not equal to 0, the arrays rpSamplesLXCb and rpSamplesLXCcr are derived by invoking the bilinear sample interpolation process specified in clause I.8.5.3.3.3.2 with the luma locations (xCb, yCb) and (xBl, yBl), the luma prediction block width nPbW, the luma prediction block height nPbH, the motion vectors mvLX equal to mvRp, and, when ChromaArrayType is not equal to 0, the motion vector mvCLX equal to mvRpC, the reference array rpPicLXL and, when ChromaArrayType is not equal to 0, the arrays rpPicLXCb and rpPicLXCcr as inputs.
- The array rpRefSamplesLXL and, when ChromaArrayType is not equal to 0, the arrays rpRefSamplesLXCb and rpRefSamplesLXCcr are derived as follows:
 - Let the reference sample array rpRefPicLXL correspond to the decoded sample array SL derived in clause 8.7 for the previously decoded picture rpRefPic.
 - When ChromaArrayType is not equal to 0, let the reference sample arrays rpRefPicLXCb and rpRefPicLXCcr correspond to the decoded sample arrays SCb and SCr, respectively, derived in clause 8.7 for the previously decoded picture rpRefPic.
 - The array rpRefSamplesLXL and, when ChromaArrayType is not equal to 0, the arrays rpRefSamplesLXCb and rpRefSamplesLXCcr are derived by invoking the bilinear sample interpolation process specified in clause I.8.5.3.3.3.2 with the luma locations (xCb, yCb) and (xBl, yBl), the luma prediction block width nPbW, the luma prediction block height nPbH, the motion vector mvLX equal to (mvLX + mvRp), and, when ChromaArrayType is not equal to 0, the motion vector mvCLX equal to (mvCLX + mvRpC), the reference arrays with rpRefPicLXL, and, when ChromaArrayType is not equal to 0, the arrays rpRefPicLXCb and rpRefPicLXCcr as inputs.
- The variable shiftVal is set equal to (iv_res_pred_weight_idx[xCb][yCb] – 1).
- The modified prediction samples predSamplesLXL[x][y] with $x = 0..(nPbW) - 1$ and $y = 0..(nPbH) - 1$ are derived as follows:

$$\text{predSamplesLXL}[x][y] = \text{predSamplesLXL}[x][y] + ((\text{rpSamplesLXL}[x][y] - \text{rpRefSamplesLXL}[x][y]) \gg \text{shiftVal}) \quad (\text{I-234})$$

- When ChromaArrayType is not equal to 0 and nPbW is greater than 8, the following applies:
 - The modified prediction samples predSamplesLXCb[x][y] with $x = 0..(nPbW / \text{SubWidthC}) - 1$ and $y = 0..(nPbH / \text{SubHeightC}) - 1$ are derived as follows:

$$\text{predSamplesLXCb}[x][y] = \text{predSamplesLXCb}[x][y] + ((\text{rpSamplesLXCb}[x][y] - \text{rpRefSamplesLXCb}[x][y]) \gg \text{shiftVal}) \quad (\text{I-235})$$

- The modified prediction samples predSamplesLXCcr[x][y] with $x = 0..(nPbW / \text{SubWidthC}) - 1$ and $y = 0..(nPbH / \text{SubHeightC}) - 1$ are derived as follows:

$$\text{predSamplesLXCcr}[x][y] = \text{predSamplesLXCcr}[x][y] + ((\text{rpSamplesLXCcr}[x][y] - \text{rpRefSamplesLXCcr}[x][y]) \gg \text{shiftVal}) \quad (\text{I-236})$$

I.8.5.3.3.2 Bilinear sample interpolation process

The specifications in clause 8.5.3.3.1 apply with the following modifications:

- All invocations of the process specified in clause 8.5.3.3.3.2 are replaced with invocations of the process specified in clause I.8.5.3.3.3.3 with chromaFlag equal to 0 as additional input.
- All invocations of the process specified in clause 8.5.3.3.3.3 are replaced with invocations of the process specified in clause I.8.5.3.3.3.3 with chromaFlag equal to 1 as additional input.

I.8.5.3.3.3.3 Bilinear luma and chroma sample interpolation process

Inputs to this process are:

- a location in full-sample units (xInt, yInt),
- a location offset in fractional-sample units (xFrac, yFrac),
- a sample reference sample array refPicLX,
- a flag chromaFlag.

Output of this process is a predicted sample value predSampleLX.

Depending on the value of chromaFlag, the following applies:

- If chromaFlag is equal 0, the following applies:
 - The variables xFrac and yFrac are set equal to (xFrac << 1) and (yFrac << 1), respectively.
 - The variables picWidth and picHeight are set equal to pic_width_in_luma_samples and pic_height_in_luma_samples, respectively.
- Otherwise (chromaFlag is equal to 1), the variables picWidth and picHeight are set equal to PicWidthInSamplesC and PicHeightInSamplesC, respectively.

In Figure 8-5, the positions labelled with upper-case letters $B_{i,j}$ within shaded blocks represent samples at full-sample locations inside the given two-dimensional array refPicLX of samples. These samples may be used for generating the predicted sample value predSampleLX. The locations ($x_{B_{i,j}}$, $y_{B_{i,j}}$) for each of the corresponding samples $B_{i,j}$ inside the given array refPicLX of samples are derived as follows:

$$x_{B_{i,j}} = \text{Clip3}(0, \text{picWidth} - 1, x_{\text{Int}} + i) \quad (\text{I-237})$$

$$y_{B_{i,j}} = \text{Clip3}(0, \text{picHeight} - 1, y_{\text{Int}} + j) \quad (\text{I-238})$$

The positions labelled with lower-case letters within un-shaded blocks represent samples at eighth-pel sample fractional locations. The location offset in fractional-sample units (xFrac, yFrac) specifies which of the generated samples at full-sample and fractional-sample locations is assigned to the predicted sample value predSampleLX. This assignment is as specified in Table 8-9, with xFracC, yFracC, and predSampleLXC replaced by xFrac, yFrac, and predSampleLX, respectively. The output is the value of predSampleLX.

The variables shift1, shift2, and shift3 are derived as follows:

- The variable bitDepth is set equal to chromaFlag ? BitDepthC : BitDepthY.
- The variable shift1 is set equal to Min(4, bitDepth – 8), the variable shift2 is set equal to 6, and the variable shift3 is set equal to Max(2, 14 – bitDepth).

Given the samples $B_{i,j}$ at full-sample locations ($x_{B_{i,j}}$, $y_{B_{i,j}}$), the samples $ab_{0,0}$ to $hh_{0,0}$ at fractional sample positions are derived as follows:

- The samples labelled $ab_{0,0}$, $ac_{0,0}$, $ad_{0,0}$, $ae_{0,0}$, $af_{0,0}$, $ag_{0,0}$, and $ah_{0,0}$ are derived by applying a 2-tap filter to the nearest integer position samples as follows:

$$ab_{0,0} = (56 * B_{0,0} + 8 * B_{1,0}) \gg \text{shift1} \quad (\text{I-239})$$

$$ac_{0,0} = (48 * B_{0,0} + 16 * B_{1,0}) \gg \text{shift1} \quad (\text{I-240})$$

$$ad_{0,0} = (40 * B_{0,0} + 24 * B_{1,0}) \gg \text{shift1} \quad (\text{I-241})$$

$$ae_{0,0} = (32 * B_{0,0} + 32 * B_{1,0}) \gg \text{shift1} \quad (\text{I-242})$$

$$af_{0,0} = (24 * B_{0,0} + 40 * B_{1,0}) \gg \text{shift1} \quad (\text{I-243})$$

$$ag_{0,0} = (16 * B_{0,0} + 48 * B_{1,0}) \gg \text{shift1} \quad (\text{I-244})$$

$$ah_{0,0} = (8 * B_{0,0} + 56 * B_{1,0}) \gg \text{shift1} \quad (\text{I-245})$$

- The samples labelled $ba_{0,0}$, $ca_{0,0}$, $da_{0,0}$, $ea_{0,0}$, $fa_{0,0}$, $ga_{0,0}$, and $ha_{0,0}$ are derived by applying a 2-tap filter to the nearest

integer position samples as follows:

$$ba_{0,0} = (56 * B_{0,0} + 8 * B_{0,1}) \gg \text{shift1} \quad (\text{I-246})$$

$$ca_{0,0} = (48 * B_{0,0} + 16 * B_{0,1}) \gg \text{shift1} \quad (\text{I-247})$$

$$da_{0,0} = (40 * B_{0,0} + 24 * B_{0,1}) \gg \text{shift1} \quad (\text{I-248})$$

$$ea_{0,0} = (32 * B_{0,0} + 32 * B_{0,1}) \gg \text{shift1} \quad (\text{I-249})$$

$$fa_{0,0} = (24 * B_{0,0} + 40 * B_{0,1}) \gg \text{shift1} \quad (\text{I-250})$$

$$ga_{0,0} = (16 * B_{0,0} + 48 * B_{0,1}) \gg \text{shift1} \quad (\text{I-251})$$

$$ha_{0,0} = (8 * B_{0,0} + 56 * B_{0,1}) \gg \text{shift1} \quad (\text{I-252})$$

- The samples labelled $bX_{0,0}$, $cX_{0,0}$, $dX_{0,0}$, $eX_{0,0}$, $fX_{0,0}$, $gX_{0,0}$, and $hX_{0,0}$ for X being replaced by b, c, d, e, f, g, and h, respectively, are derived by applying a 2-tap filter to the intermediate values $aX_{0,i}$ with $i = 0..1$ in the vertical direction as follows:

$$bX_{0,0} = (56 * aX_{0,0} + 8 * aX_{0,1}) \gg \text{shift2} \quad (\text{I-253})$$

$$cX_{0,0} = (48 * aX_{0,0} + 16 * aX_{0,1}) \gg \text{shift2} \quad (\text{I-254})$$

$$dX_{0,0} = (40 * aX_{0,0} + 24 * aX_{0,1}) \gg \text{shift2} \quad (\text{I-255})$$

$$eX_{0,0} = (32 * aX_{0,0} + 32 * aX_{0,1}) \gg \text{shift2} \quad (\text{I-256})$$

$$fX_{0,0} = (24 * aX_{0,0} + 40 * aX_{0,1}) \gg \text{shift2} \quad (\text{I-257})$$

$$gX_{0,0} = (16 * aX_{0,0} + 48 * aX_{0,1}) \gg \text{shift2} \quad (\text{I-258})$$

$$hX_{0,0} = (8 * aX_{0,0} + 56 * aX_{0,1}) \gg \text{shift2} \quad (\text{I-259})$$

I.8.5.3.3.4 Residual prediction motion vector scaling process

Inputs to this process are:

- a prediction list indication variable X,
- a motion vector mvLX,
- a reference picture (associated with the motion vector mvLX) refPicLX.

Output of this process is a scaled motion vector mvLX.

The motion vector mvLX is scaled as follows:

$$tx = (16384 + (\text{Abs}(td) \gg 1)) / td \quad (\text{I-260})$$

$$\text{distScaleFactor} = \text{Clip3}(-4096, 4095, (tb * tx + 32) \gg 6) \quad (\text{I-261})$$

$$\text{mv} = \text{Clip3}(-32768, 32767, \text{Sign}(\text{distScaleFactor} * \text{mvLX}) * ((\text{Abs}(\text{distScaleFactor} * \text{mvLX}) + 127) \gg 8)) \quad (\text{I-262})$$

where td and tb are derived as:

$$td = \text{Clip3}(-128, 127, \text{DiffPicOrderCnt}(\text{CurrPic}, \text{refPicLX})) \quad (\text{I-263})$$

$$tb = \text{Clip3}(-128, 127, \text{DiffPicOrderCnt}(\text{CurrPic}, \text{RefPicListX}[\text{RpRefIdxLX}])) \quad (\text{I-264})$$

I.8.5.3.3.5 Derivation process for a motion vector from a reference block for residual prediction

Inputs to this process are:

- a luma location (xPb, yPb) of the top-left sample of the current luma prediction block relative to the top-left luma sample of the current picture,
- two variables nPbW and nPbH specifying the width and the height of the current luma prediction block,
- a reference picture refPic,
- a disparity vector dispVec.

Outputs of this process are:

- a flag availFlag,

- a motion vector mvT ,
- a prediction list indication variable Y .

The flag $availFlag$ is set equal to 0, the motion vector mvT is set equal to (0, 0), and the prediction list indication variable Y is set equal to 0.

The reference luma location ($xRef$, $yRef$) in $refPic$ is derived as follows:

$$xRefFull = xPb + (nPbW \gg 1) + ((dispVec[0] + 2) \gg 2) \quad (I-265)$$

$$yRefFull = yPb + (nPbH \gg 1) + ((dispVec[1] + 2) \gg 2) \quad (I-266)$$

$$xRef = Clip3(0, pic_width_in_luma_samples - 1, (xRefFull \gg 3) \ll 3) \quad (I-267)$$

$$yRef = Clip3(0, pic_height_in_luma_samples - 1, (yRefFull \gg 3) \ll 3) \quad (I-268)$$

Let $refPb$ be the luma prediction block covering the luma position ($xRef$, $yRef$) in the picture $refPic$.

The variable $cuPredModeRef[x][y]$ is set equal to $CuPredMode[x][y]$ of the picture $refPic$.

When $cuPredModeRef[xRef][yRef]$ is equal to $MODE_SKIP$ or $MODE_INTER$, the following applies for X in the range of 0 to 1, inclusive:

- The variables $predFlagRef[x][y]$, $mvRef[x][y]$, and $refIdxRef[x][y]$ are set equal to $PredFlagLX[x][y]$, $MvLX[x][y]$, and $RefIdxLX[x][y]$, respectively, of picture $refPic$.
- The variable $refPicListRef$ is set equal to $RefPicListX$ of the slice containing $refPb$ in the picture $refPic$.
- When $availFlag$ is equal to 0, $predFlagRef[xRef][yRef]$ is equal to 1, $DiffPicOrderCnt(refPic, refPicListRef[refIdxRef[xRef][xRef]])$ is not equal to 0, and $RpRefPicAvailFlagLX$ is equal to 1, the following applies:
 - The variable $availFlag$ is set equal to 1.
 - The variable Y is set equal to X .
 - The residual prediction motion vector scaling process as specified in clause I.8.5.3.3.4 is invoked with the prediction list indication variable equal to X , the motion vector $mvRef[xRef][yRef]$, and the reference picture $refPicListRef[refIdxRef[xRef][xRef]]$ as inputs, and the output being the motion vector mvT .

I.8.5.3.4 Decoding process for inter sample prediction for rectangular sub-block partitions

Inputs to this process are:

- a luma location (xCb , yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a luma location (xBI , yBI) specifying the top-left sample of the current luma prediction block relative to the top-left sample of the current luma coding block,
- a variable $nCbS$ specifying the size of the current luma coding block,
- two variables $nPbW$ and $nPbH$ specifying the width and the height of the luma prediction block.

Outputs of this process are:

- an $(nCbSL) \times (nCbSL)$ array $predSamples_L$ of luma prediction samples, where $nCbSL$ is derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $predSamples_{Cb}$ of chroma prediction samples for the component Cb , where $nCbSw_C$ and $nCbSh_C$ are derived as specified below,
- when $ChromaArrayType$ is not equal to 0, an $(nCbSw_C) \times (nCbSh_C)$ array $predSamples_{Cr}$ of chroma prediction samples for the component Cr , where $nCbSw_C$ and $nCbSh_C$ are derived as specified below.

When $ChromaArrayType$ is not equal to 0, the variable $nCbSw_C$ is set equal to ($nCbS / SubWidthC$) and the variable $nCbSh_C$ is set equal to ($nCbS / SubHeightC$).

The luma location (xPb , yPb) specifying the top-left sample of the current luma prediction block relative to the top-left sample of the current picture is set equal to ($xCb + xBI$, $yCb + yBI$).

The variables $nSbW$ and $nSbH$ specifying the width and height of the sub-block partitions are derived as follows:

$$(nSbW, nSbH) = SubPbArrayPartSize[xPb][yPb] \quad (I-269)$$

For x in the range of 0 to ($nPbW / nSbW - 1$), inclusive, the following applies:

- For y in the range of 0 to $(n_{PbH} / n_{SbH} - 1)$, inclusive, the following applies:
 - The luma location (x_{Sb}, y_{Sb}) specifying the top-left sample of the current luma sub-block partition relative to the top-left sample of the current luma coding block is derived as follows:

$$x_{Sb} = x_{Bl} + x * n_{SbW} \quad (I-270)$$

$$y_{Sb} = y_{Bl} + y * n_{SbH} \quad (I-271)$$
 - For X in the range of 0 to 1, inclusive, the variables $mvLX$, $mvCLX$, $refIdxLX$, and $predFlagLX$ are derived as follows:

$$mvLX = \text{SubPbArrayMvLX}[x_{Cb} + x_{Sb}][y_{Cb} + y_{Sb}] \quad (I-272)$$

$$mvCLX = (\text{ChromaArrayType} \neq 0) ? \text{SubPbArrayMvCLX}[x_{Cb} + x_{Sb}][y_{Cb} + y_{Sb}] : (0, 0) \quad (I-273)$$

$$refIdxLX = \text{SubPbArrayRefIdxLX}[x_{Cb} + x_{Sb}][y_{Cb} + y_{Sb}] \quad (I-274)$$

$$predFlagLX = \text{SubPbArrayPredFlagLX}[x_{Cb} + x_{Sb}][y_{Cb} + y_{Sb}] \quad (I-275)$$
 - The decoding process for inter sample prediction as specified in clause I.8.5.3.3.1 is invoked with the luma coding block location (x_{Cb}, y_{Cb}) , the luma prediction block location (x_{Bl}, y_{Bl}) equal to (x_{Sb}, y_{Sb}) , the luma coding block size n_{CbS} , the luma prediction block width n_{PbW} equal to n_{SbW} , the luma prediction block height n_{PbH} equal to n_{SbH} , the luma motion vectors $mvL0$ and $mvL1$, when ChromaArrayType is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$, the reference indices $refIdxL0$ and $refIdxL1$, and the prediction list utilization flags $predFlagL0$ and $predFlagL1$ as inputs, and the inter prediction samples that are an $(n_{CbSL}) \times (n_{CbSL})$ array $predSamples_L$ of prediction luma samples, and, when ChromaArrayType is not equal to 0, two $(n_{CbSwC}) \times (n_{CbShC})$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$ of prediction chroma samples, one for each of the chroma components Cb and Cr , as outputs.

I.8.5.3.5 Decoding process for inter sample prediction for depth predicted sub-block partitions

I.8.5.3.5.1.1 General

Inputs to this process are:

- a luma location (x_{Cb}, y_{Cb}) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable n_{CbS} specifying the size of the current luma coding block,
- two luma motion vectors $mvL0$ and $mvL1$,
- when ChromaArrayType is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$,
- two reference indices $refIdxL0$ and $refIdxL1$,
- two prediction list utilization flags $predFlagL0$, and $predFlagL1$,
- a variable $partIdx$ specifying the index of the current prediction unit within the current coding unit.

Outputs of this process are:

- an $(n_{CbSL}) \times (n_{CbSL})$ array $predSamples_L$ of luma prediction samples, where n_{CbSL} is derived as specified below,
- when ChromaArrayType is not equal to 0, an $(n_{CbSwC}) \times (n_{CbShC})$ array $predSamples_{Cb}$ of chroma prediction samples for the component Cb , where n_{CbSwC} and n_{CbShC} are derived as specified below,
- when ChromaArrayType is not equal to 0, an $(n_{CbSwC}) \times (n_{CbShC})$ array $predSamples_{Cr}$ of chroma prediction samples for the component Cr , where n_{CbSwC} and n_{CbShC} are derived as specified below.

The variable n_{CbSL} is set equal to n_{CbS} . When ChromaArrayType is not equal to 0, the variable n_{CbSwC} is set equal to $n_{CbS} / \text{SubWidthC}$ and the variable n_{CbShC} is set equal to $n_{CbS} / \text{SubHeightC}$.

The decoding process for inter sample prediction as specified in clause I.8.5.3.3.1 is invoked with the luma coding block location (x_{Cb}, y_{Cb}) , the luma prediction block location (x_{Bl}, y_{Bl}) set to $(0, 0)$, the luma coding block size n_{CbS} , the luma prediction block width n_{PbW} equal to n_{CbS} , the luma prediction block height n_{PbH} equal to n_{CbS} , the luma motion vectors $mvL0$ and $mvL1$, when ChromaArrayType is not equal to 0, the chroma motion vectors $mvCL0$ and $mvCL1$, the reference indices $refIdxL0$ and $refIdxL1$, and the prediction list utilization flags $predFlagL0$ and $predFlagL1$ as inputs, and the inter prediction samples ($predSamples$) that are an $(n_{CbSL}) \times (n_{CbSL})$ array $predSamples_L$ of prediction luma samples and, when ChromaArrayType is not equal to 0, two $(n_{CbSwC}) \times (n_{CbShC})$ arrays $predSamples_{Cb}$ and $predSamples_{Cr}$ of prediction chroma samples, one for each of the chroma components Cb and Cr , as outputs.

The partition pattern contourPattern is derived as follows:

- The derivation process for a depth or disparity sample array from a depth picture as specified in clause I.8.5.7 is invoked with the luma location (xBlk, yBlk) equal to (xCb, yCb), the variable nBlkW equal to nCbS, the variable nBlkH equal to nCbS, the disparity vector dispVec equal to DispRefVec[xCb][yCb], the reference view order index refViewIdx equal to RefViewIdx[xCb][yCb], and the variable partIdx equal to 1 as inputs, and the output is the array refSamples of size (nCbS)x(nCbS).

- The variable threshVal is derived as follows:

$$\text{threshVal} = (\text{refSamples}[0][0] + \text{refSamples}[0][\text{nCbS} - 1] + \text{refSamples}[\text{nCbS} - 1][0] + \text{refSamples}[\text{nCbS} - 1][\text{nCbS} - 1]) \gg 2 \quad (\text{I-276})$$

- For $x = 0.. \text{nCbS} - 1$ and $y = 0.. \text{nCbS} - 1$, the following applies:

$$\text{contourPattern}[x][y] = (\text{refSamples}[x][y] > \text{threshVal}) \quad (\text{I-277})$$

The array TempSamplesDbbp_L and, when ChromaArrayType is not equal to 0, the arrays TempSamplesDbbp_{Cb} and TempSamplesDbbp_{Cr} are modified as follows:

```
for( y = 0; y < nCbSL; y++ )
  for( x = 0; x < nCbSL; x++ )
    if( contourPattern[ x ][ y ] == ( partIdx != contourPattern[ 0 ][ 0 ] ) ) {
      TempSamplesDbbpL[ x ][ y ] = predSamplesL[ x ][ y ]
      if( ChromaArrayType != 0 && ( x % SubWidthC ) == 0 && ( y % SubHeightC ) == 0 ) {
        xC = x / SubWidthC
        yC = y / SubHeightC
        TempSamplesDbbpCb[ xC ][ yC ] = predSamplesCb[ xC ][ yC ]
        TempSamplesDbbpCr[ xC ][ yC ] = predSamplesCr[ xC ][ yC ]
      }
    }
```

(I-278)

When partIdx is equal to 1, the array predSamples_L and, when ChromaArrayType is not equal to 0, the arrays predSamples_{Cb} and predSamples_{Cr} are modified as follows:

- The derivation process for contour boundary filtered samples as specified in clause I.8.5.3.5.1.2 is invoked with, the luma coding block size nCbS_L, the current coding block width nCbSw equal to nCbS_L, the current coding block height nCbSh equal to nCbS_L, the partition pattern contourPattern, and the array predSamples of prediction samples equal to TempSamplesDbbp_L as inputs, and the output is assigned to the array predSamples_L of luma prediction samples.
- When ChromaArrayType is not equal to 0, the derivation process for contour boundary filtered samples as specified in clause I.8.5.3.5.1.2 is invoked with, the luma coding block size nCbS_L, the current coding block width nCbSw equal to nCbSw_C, the current coding block height nCbSh equal to nCbSh_C, the partition pattern contourPattern, and the array predSamples of prediction samples equal to TempSamplesDbbp_{Cb} as inputs, and the output is assigned to the array predSamples_{Cb} of chroma prediction samples.
- When ChromaArrayType is not equal to 0, the derivation process for contour boundary filtered samples as specified in clause I.8.5.3.5.1.2 is invoked with, the luma coding block size nCbS_L, the current coding block width nCbSw equal to nCbSw, the current coding block height nCbSh equal to nCbSh_C, the partition pattern contourPattern, and the array predSamples of prediction samples equal to TempSamplesDbbp_{Cr} as inputs, and the output is assigned to the array predSamples_{Cr} of chroma prediction samples.

I.8.5.3.5.1.2 Derivation process for contour boundary filtered samples

Inputs to this process are:

- a variable nCbS_L specifying the size of the current luma coding block,
- a variable nCbSw specifying the width of the current luma or chroma coding block,
- a variable nCbSh specifying the height of the current luma or chroma coding block,
- an (nCbS_L)x(nCbS_L) partition pattern contourPattern,
- an (nCbSw)x(nCbSh) array predSamples prediction samples.

Output of this process is a modified (nCbSw)x(nCbSh) array predSamples of prediction samples.

The (nCbSw)x(nCbSh) array p is set equal to predSamples.

The variable xOff, yOff, nCbS_N, and n are derived as follows:

- If PartMode is equal to PART_Nx2N, xOff is set equal to 1, yOff is set equal to 0, nCbS_N is set equal to nCbSw, and n is set equal to (nCbS_L / nCbSw).
- Otherwise (PartMode is not equal to PART_Nx2N), xOff is set equal to 0, yOff is set equal to 1, nCbS_N is set equal to nCbSh, and n is set equal to (nCbS_L / nCbSh).

The values of predSamples are derived as follows:

```

for( y = 0; y < nCbSh; y++ )
  for( x = 0; x < nCbSw; x++ ) {
    filt = p[ x ][ y ]
    prevFlag = contourPattern[ Max( 0, n * ( x - xOff ) ) ][ Max( 0, n * ( y - yOff ) ) ]
    nextFlag = contourPattern[ Min( n * ( x + xOff ), nCbSL - 1 ) ][ Min( n * ( y + yOff ), nCbSL - 1 ) ]
    if( prevFlag != nextFlag )
      filt = ( p[ Max( 0, x - xOff ) ][ Max( 0, y - yOff ) ] + ( filt << 1 ) +
        p[ Min( x + xOff, nCbSN - 1 ) ][ Min( y + yOff, nCbSN - 1 ) ] ) >> 2
    predSamples[ x ][ y ] = filt
  }

```

(I-279)

I.8.5.4 Decoding process for the residual signal of coding units coded in inter prediction mode

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable log2CbSize specifying the size of the current luma coding block.

Outputs of this process are:

- an (nCbS_L)x(nCbS_L) array resSamples_L of luma residual samples, where nCbS_L is derived as specified below,
- when ChromaArrayType is not equal to 0, an (nCbSw_C)x(nCbSh_C) array resSamples_{Cb} of chroma residual samples for the component Cb, where nCbSw_C and nCbSh_C are derived as specified below,
- when ChromaArrayType is not equal to 0, an (nCbSw_C)x(nCbSh_C) array resSamples_{Cr} of chroma residual samples for the component Cr, where nCbSw_C and nCbSh_C are derived as specified below.

The variable nCbS_L is set equal to 1 << log2CbSize. When ChromaArrayType is not equal to 0, the variable nCbSw_C is set equal to nCbS_L / SubWidthC and the variable nCbSh_C is set equal to nCbS_L / SubHeightC.

Let resSamples_L be an (nCbS_L)x(nCbS_L) array of luma residual samples and, when ChromaArrayType is not equal to 0, let resSamples_{Cb} and resSamples_{Cr} be two (nCbSw_C)x(nCbSh_C) arrays of chroma residual samples.

- If DcOnlyFlag[xCb][yCb] is equal to 0, the following applies, depending on the value of rqt_root_cbf:
 - If rqt_root_cbf is equal to 0 or cu_skip_flag[xCb][yCb] is equal to 1, all samples of the (nCbS_L)x(nCbS_L) array resSamples_L and, when ChromaArrayType is not equal to 0, all samples of the two (nCbSw_C)x(nCbSh_C) arrays resSamples_{Cb} and resSamples_{Cr} are set equal to 0.
 - Otherwise (rqt_root_cbf is equal to 1), the following ordered steps apply:
 1. The decoding process for luma residual blocks as specified in clause 8.5.4.2 is invoked with the luma location (xCb, yCb), the luma location (xB0, yB0) set equal to (0, 0), the variable log2TrafoSize set equal to log2CbSize, the variable trafoDepth set equal to 0, the variable nCbS set equal to nCbS_L, and the (nCbS_L)x(nCbS_L) array resSamples_L as inputs, and a modified version of the (nCbS_L)x(nCbS_L) array resSamples_L as output.
 2. When ChromaArrayType is not equal to 0, the decoding process for chroma residual blocks as specified in clause 8.5.4.3 is invoked with the luma location (xCb, yCb), the luma location (xB0, yB0) set equal to (0, 0), the variable log2TrafoSize set equal to log2CbSize, the variable trafoDepth set equal to 0, the variable cIdx set equal to 1, the variable nCbSw set equal to nCbSw_C, the variable nCbSh set equal to nCbSh_C, and the (nCbSw_C)x(nCbSh_C) array resSamples_{Cb} as inputs, and a modified version of the (nCbSw_C)x(nCbSh_C) array resSamples_{Cb} as output.
 3. When ChromaArrayType is not equal to 0, the decoding process for chroma residual blocks as specified in clause 8.5.4.3 is invoked with the luma location (xCb, yCb), the luma location (xB0, yB0) set equal to (0, 0), the variable log2TrafoSize set equal to log2CbSize, the variable trafoDepth set equal to 0, the variable cIdx set equal to 2, the variable nCbSw set equal to nCbSw_C, the variable nCbSh set equal to nCbSh_C, and the (nCbSw_C)x(nCbSh_C) array resSamples_{Cr} as inputs, and a modified version of the (nCbSw_C)x(nCbSh_C) array resSamples_{Cr} as output.

- Otherwise ($\text{DcOnlyFlag}[x_{Cb}][y_{Cb}]$ is equal to 1), for x in the range of 0 to $\text{nCbS}_L - 1$, inclusive, and y in the range of 0 to $\text{nCbS}_L - 1$, inclusive, $\text{resSamples}_L[x][y]$ is set equal to $\text{DcOffset}[x_{Cb}][y_{Cb}][0]$.

NOTE – When $\text{DcOnlyFlag}[x_{Cb}][y_{Cb}]$ is equal to 1, ChromaArrayType is equal to 0 in this version of this Specification.

1.8.5.5 Derivation process for a disparity vector for texture layers

1.8.5.5.1 General

Inputs to this process are:

- a luma location (x_{Cb}, y_{Cb}) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable nCbS specifying the size of the current luma coding block.

The flag dvAvailFlag is set equal to 0 and the disparity vector dispVec is set equal to (0, 0).

The variable $\text{checkParallelMergeFlag}$ is derived as follows:

- If one or more of the following conditions are true, $\text{checkParallelMergeFlag}$ is set equal to 1:
 - $\text{CuPredMode}[x_{Cb}][y_{Cb}]$ is equal to MODE_SKIP .
 - $\text{CuPredMode}[x_{Cb}][y_{Cb}]$ is equal to MODE_INTER and $\text{merge_flag}[x_{Cb}][y_{Cb}]$ is equal to 1.
- Otherwise, $\text{checkParallelMergeFlag}$ is set equal to 0.

When $\text{slice_temporal_mvp_enabled_flag}$ is equal to 1, the derivation process for a disparity vector from temporal neighbouring blocks as specified in clause 1.8.5.5.2 is invoked with the luma location (x_{Cb}, y_{Cb}), and the variable nCbS as inputs, and the outputs are the flag dvAvailFlag , the disparity vector dispVec , and the reference view order index refViewIdx .

When dvAvailFlag is equal to 0, the following applies for i in the range of 0 to 1, inclusive:

1. The variable N is set equal to $(i == 0) ? A_1 : B_1$.
2. The variable (x_N, y_N) is set equal to $(i == 0) ? (x_{Cb} - 1, y_{Cb} + \text{nCbS} - 1) : (x_{Cb} + \text{nCbS} - 1, y_{Cb} - 1)$.
3. The derivation process for z-scan order block availability as specified in clause 6.4.1 is invoked with (x_{Curr}, y_{Curr}) set equal to the (x_{Cb}, y_{Cb}) and the luma location (x_N, y_N) as inputs, and the output is assigned to nbAvailFlag .
4. When $\text{CuPredMode}[x_N][y_N]$ is equal to MODE_INTRA , nbAvailFlag is set equal to 0.
5. When all of the following conditions are true, nbAvailFlag is set equal to 0.
 - $\text{checkParallelMergeFlag}$ is equal to 1,
 - $(x_{Cb} \gg \text{Log2ParMrgLevel})$ is equal to $(x_N \gg \text{Log2ParMrgLevel})$,
 - $(y_{Cb} \gg \text{Log2ParMrgLevel})$ is equal to $(y_N \gg \text{Log2ParMrgLevel})$.
6. The flag tPredNbAvailFlag is set equal to nbAvailFlag .
7. When N is equal to B_1 and $((y_N \gg \text{CtbLog2SizeY}) \ll \text{CtbLog2SizeY})$ is less than $((y_{Cb} \gg \text{CtbLog2SizeY}) \ll \text{CtbLog2SizeY})$, tPredNbAvailFlag is set equal to 0.
8. The flag $\text{tPredNbDvAvailFlagN}$ is set equal to 0.
9. For X in the range of 0 to 1, inclusive, the following applies:
 - When dvAvailFlag is equal to 0, nbAvailFlag is equal to 1, and $\text{PredFlagLX}[x_N][y_N]$ is equal to 1, the following applies:
 - If $\text{DiffPicOrderCnt}(\text{RefPicListX}[\text{RefIdxLX}[x_N][y_N]], \text{CurrPic})$ is equal to 0, the following applies:

$$\text{refViewIdx} = \text{ViewIdx}(\text{RefPicListX}[\text{RefIdxLX}[x_N][y_N]]) \quad (\text{I-280})$$

$$\text{dispVec} = \text{MvLXN}[x_N][y_N] \quad (\text{I-281})$$

$$\text{dvAvailFlag} = 1 \quad (\text{I-282})$$
 - Otherwise ($\text{DiffPicOrderCnt}(\text{RefPicListX}[\text{RefIdxLX}[x_N][y_N]], \text{CurrPic})$ is not equal to 0), when tPredNbAvailFlag is equal to 1, $\text{tPredNbDvAvailFlagN}$ is equal to 0, $\text{CuPredMode}[x_N][y_N]$ is equal to MODE_SKIP , and $\text{lvMcFlag}[x_N][y_N]$ is equal to 1, the following applies:

$$tPredNbDispVecN = DispRefVec[xN][yN] \quad (I-283)$$

$$tPredNbRefViewIdxN = RefViewIdx[xN][yN] \quad (I-284)$$

$$tPredNbDvAvailFlagN = 1 \quad (I-285)$$

For i in the range of 0 to 1, inclusive, the following applies:

- The variable N is set equal to $(i == 0) ? A_1 : B_1$.
- When $dvAvailFlag$ is equal to 0 and $tPredNbDvAvailFlagN$ is equal to 1, the following applies:

$$dispVec = tPredNbDispVecN \quad (I-286)$$

$$refViewIdx = tPredNbRefViewIdxN \quad (I-287)$$

$$dvAvailFlag = 1 \quad (I-288)$$

When $dvAvailFlag$ is equal to 0, $refViewIdx$ is set equal to $DefaultRefViewIdx$ and $dispVec$ is set equal to $(0, 0)$.

Depending on the value of $DepthRefEnabledFlag$, the following applies:

- If $DepthRefEnabledFlag$ is equal to 1, the following applies:
 - The derivation process for a depth or disparity sample array from a depth picture as specified in clause I.8.5.7 is invoked with the luma location $(xBlk, yBlk)$ equal to (xCb, yCb) , the variable $nBlkW$ equal to $nCbS$, the variable $nBlkH$ equal to $nCbS$, the disparity vector $dispVec$, the reference view order index $refViewIdx$, and the variable $partIdx$ equal to 0 as inputs, and the array $disparitySamples$ of size $(nCbS) \times (nCbS)$ as output.
 - The disparity vector $dispRefVec$ is set equal to $(disparitySamples[0][0], 0)$.
- Otherwise ($DepthRefEnabledFlag$ is equal to 0), the disparity vector $dispRefVec$ is set equal to $dispVec$.

For use in derivation processes of variables invoked later in the decoding process, the following assignments are made for $x = xCb.(xCb + nCbS - 1)$, $y = yCb.(yCb + nCbS - 1)$:

$$DispVec[x][y] = dispVec \quad (I-289)$$

$$DispRefVec[x][y] = dispRefVec \quad (I-290)$$

$$RefViewIdx[x][y] = refViewIdx \quad (I-291)$$

I.8.5.5.2 Derivation process for a disparity vector from temporal neighbouring blocks

Inputs to this process are:

- a luma location (xCb, yCb) specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable $nCbS$ specifying the size of the current luma coding block.

Outputs of this process are:

- the availability flag $dvAvailFlag$,
- the disparity vector $dispVec$,
- the reference view order index $refViewIdx$.

The luma location $(xRef, yRef)$ is derived as follows:

$$xRef = ((xCb + nCbS / 2) >> 4) << 4 \quad (I-292)$$

$$yRef = ((yCb + nCbS / 2) >> 4) << 4 \quad (I-293)$$

The flag $dvAvailFlag$ is set equal to 0 and $dispVec$ is set equal to $(0, 0)$.

For i from 0 to $NumDdvCandPics - 1$, inclusive, the following ordered steps apply:

1. Let $colPb$ the luma prediction block covering the luma location $(xRef, yRef)$ in picture $DdvCandPicList[i]$.
2. For X in the range of 0 to 1, inclusive, the following applies:
 - The variables $candPredFlag[x][y]$, $candRefIdx[x][y]$, and $candMV[x][y]$ are set equal to the variables $PredFlagLX[x][y]$, $RefIdxLX[x][y]$, and $MvLX[x][y]$ of the picture $DdvCandPicList[i]$, respectively.

- The variable `candPicRefPicList` is set equal to `RefPicListX` of the slice containing `colPb` in the picture `DdvCandPicList[i]`.
- When `colPb` is not coded in an intra prediction mode and `candPredFlag[xRef][yRef]` is equal to 1, the following applies:
 - The variable `candRefViewIdx` is set equal to `ViewIdx(candPicRefPicList[candRefIdx[xRef][yRef]])`.
 - When `dvAvailFlag` is equal to 0, `candRefViewIdx` is not equal to the `ViewIdx(DdvCandPicList[i])`, and there is a reference picture with `ViewIdx` equal to `candRefViewIdx` in `RefPicList0` or `RefPicList1`, the following applies:

$$\text{refViewIdx} = \text{candRefViewIdx} \quad (\text{I-294})$$

$$\text{dispVec} = \text{candMV}[\text{xRef}][\text{yRef}] \quad (\text{I-295})$$

$$\text{dvAvailFlag} = 1 \quad (\text{I-296})$$

1.8.5.6 Derivation process for a disparity vector for depth layers

Inputs to this process are:

- a luma location (`xCb, yCb`) of the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture,
- a variable `nCbS` specifying the size of the current luma coding block.

When `DispAvailFlag` is equal to 1, the following assignments are made for `x = xCb..(xCb + nCbS – 1)` and `y = yCb..(yCb + nCbS – 1)`:

$$\text{DispVec}[x][y] = (\text{DepthToDisparityB}[\text{DefaultRefViewIdx}][1 \ll (\text{BitDepth}_Y - 1)], 0) \quad (\text{I-297})$$

$$\text{DispRefVec}[x][y] = \text{DispVec}[x][y] \quad (\text{I-298})$$

$$\text{RefViewIdx}[x][y] = \text{DefaultRefViewIdx} \quad (\text{I-299})$$

1.8.5.7 Derivation process for a depth or disparity sample array from a depth picture

Inputs to this process are:

- a luma location (`xBlk, yBlk`) specifying the top-left sample of the current luma block relative to the top-left luma sample of the current picture,
- two variables `nBlkW` and `nBlkH` specifying the width and the height of the luma block, respectively,
- a disparity vector `dispVec`,
- a reference view order index `refViewIdx`,
- a variable `partIdx` specifying a sub-block partitioning.

Outputs of this process are:

- an $(nBlkW) \times (nBlkH)$ array `dSamples` of depth or disparity values (depending on `partIdx`),
- a flag `horSplitFlag` (when `partIdx` is equal to 2).

Let `refDepPic` be the picture in the current access unit with `nuh_layer_id` equal to `ViewCompLayerId[refViewIdx][1]`.

Let `refDepPels` be the array of reconstructed luma samples S_L of the picture `refDepPic`. The luma location (`xRefBlk, yRefBlk`) of top-left luma sample of a block in `refDepPels` is derived as follows:

$$\text{xRefBlk} = \text{xBlk} + ((\text{dispVec}[0] + 2) \gg 2) \quad (\text{I-300})$$

$$\text{yRefBlk} = \text{yBlk} + ((\text{dispVec}[1] + 2) \gg 2) \quad (\text{I-301})$$

Depending on the value of `partIdx`, the variables `nSubBlkW`, `nSubBlkH`, and `horSplitFlag` are derived as follows:

- If `partIdx` is equal to 0, the variables `nSubBlkW`, `nSubBlkH`, and `horSplitFlag` are set equal to `nBlkW`, `nBlkH`, and 0, respectively.
- Otherwise, if `partIdx` is equal to 1, the variables `nSubBlkW`, `nSubBlkH`, and `horSplitFlag` are set equal to 1, 1, and 0, respectively.
- Otherwise (`partIdx` is equal to 2), the following applies:

- The variable minSubBlkSizeFlag is derived as follows:

$$\text{minSubBlkSizeFlag} = (\text{nBlkW} \% 8 \neq 0) \mid (\text{nBlkH} \% 8 \neq 0) \quad (\text{I-302})$$

- Depending on the value of minSubBlkSizeFlag, the following applies:

- If minSubBlkSizeFlag is equal to 1, the following applies:

$$\text{horSplitFlag} = (\text{nBlkH} \% 8 \neq 0) \quad (\text{I-303})$$

- Otherwise (minSubBlkSizeFlag is equal to 0), the following applies:

$$\text{xP0} = \text{Clip3}(0, \text{pic_width_in_luma_samples} - 1, \text{xRefBlk}) \quad (\text{I-304})$$

$$\text{yP0} = \text{Clip3}(0, \text{pic_height_in_luma_samples} - 1, \text{yRefBlk}) \quad (\text{I-305})$$

$$\text{xP1} = \text{Clip3}(0, \text{pic_width_in_luma_samples} - 1, \text{xRefBlk} + \text{nBlkW} - 1) \quad (\text{I-306})$$

$$\text{yP1} = \text{Clip3}(0, \text{pic_height_in_luma_samples} - 1, \text{yRefBlk} + \text{nBlkH} - 1) \quad (\text{I-307})$$

$$\begin{aligned} \text{horSplitFlag} &= ((\text{refDepPels}[\text{xP0}][\text{yP0}] < \text{refDepPels}[\text{xP1}][\text{yP1}]) \\ &= (\text{refDepPels}[\text{xP1}][\text{yP0}] < \text{refDepPels}[\text{xP0}][\text{yP1}])) \end{aligned} \quad (\text{I-308})$$

- The variables nSubBlkW and nSubBlkH are derived as follows:

$$\text{nSubBlkW} = \text{horSplitFlag} ? 8 : 4 \quad (\text{I-309})$$

$$\text{nSubBlkH} = \text{horSplitFlag} ? 4 : 8 \quad (\text{I-310})$$

The array dSamples is derived as follows:

- For j in the range of 0 to (nBlkH / nSubBlkH – 1), inclusive, the following applies:

- For i in the range of 0 to (nBlkW / nSubBlkW – 1), inclusive, the following applies:

- The variable maxDep is set equal to –1 and modified as follows:

$$\begin{aligned} \text{xSubBlkOff} &= i * \text{nSubBlkW} \\ \text{ySubBlkOff} &= j * \text{nSubBlkH} \\ \text{xP0} &= \text{Clip3}(0, \text{pic_width_in_luma_samples} - 1, \text{xRefBlk} + \text{xSubBlkOff}) \\ \text{yP0} &= \text{Clip3}(0, \text{pic_height_in_luma_samples} - 1, \text{yRefBlk} + \text{ySubBlkOff}) \\ \text{xP1} &= \text{Clip3}(0, \text{pic_width_in_luma_samples} - 1, \text{xRefBlk} + \text{xSubBlkOff} + \text{nSubBlkW} - 1) \\ \text{yP1} &= \text{Clip3}(0, \text{pic_height_in_luma_samples} - 1, \text{yRefBlk} + \text{ySubBlkOff} + \text{nSubBlkH} - 1) \\ \text{maxDep} &= \text{Max}(\text{maxDep}, \text{refDepPels}[\text{xP0}][\text{yP0}]) \\ \text{maxDep} &= \text{Max}(\text{maxDep}, \text{refDepPels}[\text{xP0}][\text{yP1}]) \\ \text{maxDep} &= \text{Max}(\text{maxDep}, \text{refDepPels}[\text{xP1}][\text{yP0}]) \\ \text{maxDep} &= \text{Max}(\text{maxDep}, \text{refDepPels}[\text{xP1}][\text{yP1}]) \end{aligned} \quad (\text{I-311})$$

- The values of the array dSamples are derived as follows:

$$\begin{aligned} &\text{for}(\text{yOff} = 0; \text{yOff} < \text{nSubBlkH}; \text{yOff}++) \\ &\quad \text{for}(\text{xOff} = 0; \text{xOff} < \text{nSubBlkW}; \text{xOff}++) \{ \\ &\quad \quad \text{x} = \text{xSubBlkOff} + \text{xOff} \\ &\quad \quad \text{y} = \text{ySubBlkOff} + \text{yOff} \\ &\quad \quad \text{if}(\text{partIdc} == 1) \\ &\quad \quad \quad \text{dSamples}[\text{x}][\text{y}] = \text{maxDep} \\ &\quad \quad \text{else} \\ &\quad \quad \quad \text{dSamples}[\text{x}][\text{y}] = \text{DepthToDisparityB}[\text{refViewIdx}][\text{maxDep}] \\ &\quad \quad \} \end{aligned} \quad (\text{I-312})$$

I.8.6 Scaling, transformation and array construction process prior to deblocking filter process

The specifications in clause 8.6 apply.

I.8.7 In-loop filter process

The specifications in clause 8.7 apply.

I.9 Parsing process

I.9.1 General

The specifications in clause 9.1 apply with the following modifications.

- All references to the process specified in clause 9.3 are replaced with references to the process specified in clause I.9.3.

I.9.2 Parsing process for 0-th order Exp-Golomb codes

The specifications in clause 9.2 and all its subclauses apply.

I.9.3 CABAC parsing process for slice segment data

I.9.3.1 General

The specifications in clause 9.3.1 apply with the following modifications.

- All references to the process specified in clauses 7.3.8.1 to 7.3.8.12 are replaced with references to the process specified in clauses I.7.3.8.1 to I.7.3.8.12, respectively.
- All invocations of the process specified in clause 9.3.2 to 9.3.4 are replaced with invocations of the process specified in clause I.9.3.2 to I.9.3.4.
- All invocations of the process specified in clause 9.3.2.4 are replaced with invocations of the process specified in clause I.9.3.2.3.
- All invocations of the process specified in clause 9.3.2.6 are replaced with invocations of the process specified in clause I.9.3.2.5.

I.9.3.2 Initialization process

I.9.3.2.1 General

The specifications in clause 9.3.2.1 apply with the following modifications.

- All invocations of the process specified in clause 9.3.2.2 are replaced with invocations of the process specified in clause I.9.3.2.2.
- All invocations of the process specified in clause 9.3.2.5 are replaced with invocations of the process specified in clause I.9.3.2.4.
- All invocations of the process specified in clause 9.3.2.6 are replaced with invocations of the process specified in clause I.9.3.2.5.

I.9.3.2.2 Initialization process for context variables

The specifications in clause 9.3.2.2 apply with the following modifications.

- All references to the process specified in clauses 7.3.8.1 to 7.3.8.12 are replaced with references to the process specified in clauses I.7.3.8.1 to I.7.3.8.12.
- Table I.4 is appended to the end of Table 9-4.
- Table I.5 to Table I.14 are appended to the end of the clause.

Table I.4 – Association of ctxIdx and syntax elements for each initializationType in the initialization process

Syntax structure	Syntax element	ctxTable	initType		
			0	1	2
coding_unit()	skip_intra_flag	Table I.5	0	1	2
intra_mode_ext()	no_dim_flag	Table I.6	0	1	2

Table I.14 – Values of initValue for depth_dc_abs ctxIdx

Initialization variable	ctxIdx of depth_dc_abs		
	0	1	2
initValue	154	154	154

I.9.3.2.3 Storage process for context variables and Rice parameter initialization states

The specifications in clause 9.3.2.4 apply with the following modifications

- All references to the process specified in clauses 7.3.8.1 to 7.3.8.12 are replaced with references to the process specified in clauses I.7.3.8.1 to I.7.3.8.12.

I.9.3.2.4 Synchronization process for context variables and Rice parameter initialization states

The specifications in clause 9.3.2.5 apply with the following modifications

- All references to the process specified in clauses 7.3.8.1 to 7.3.8.12 are replaced with references to the process specified in clauses I.7.3.8.1 to I.7.3.8.12.

I.9.3.2.5 Initialization process for the arithmetic decoding engine

The specifications in clause 9.3.2.6 apply.

I.9.3.3 Binarization process**I.9.3.3.1 General**

The specifications in clause 9.3.3.1 apply with the following modifications.

- All references to processes clauses 9.3.3.2 to 9.3.3.11 are replaced with references to the processes specified in clauses I.9.3.3.2 and I.9.3.3.10 respectively.
- Table I.15 is appended to the end of Table 9-43.

Table I.15 – Syntax elements and associated binarizations

Syntax structure	Syntax element	Binarization	
		Process	Input parameters
coding_unit()	skip_intra_flag	FL	cMax = 1
intra_mode_ext()	no_dim_flag	FL	cMax = 1
	depth_intra_mode_idx_flag	FL	cMax = 1
	wedge_full_tab_idx	FL	cMax = NumWedgePattern[log2PbSize] – 1
cu_extension()	skip_intra_mode_idx	TR	cMax = 3, cRiceParam = 0
	dbbp_flag	FL	cMax = 1
	dc_only_flag	FL	cMax = 1
	iv_res_pred_weight_idx	TR	cMax = 2, cRiceParam = 0
	illu_comp_flag	FL	cMax = 1
depth_dcs()	depth_dc_present_flag	FL	cMax = 1
	depth_dc_abs	I.9.3.3.11	-
	depth_dc_sign_flag	FL	cMax = 1

I.9.3.3.2 Truncated Rice (TR) binarization process

The specifications in clause 9.3.3.2 apply.

I.9.3.3.3 k-th order Exp-Golomb (EGk) binarization process

The specifications in clause 9.3.3.3 apply.

I.9.3.3.4 Limited k-th order Exp-Golomb (EGk) binarization process

The specifications in clause 9.3.3.4 apply.

I.9.3.3.5 Fixed-length (FL) binarization process

The specifications in clause 9.3.3.5 apply.

I.9.3.3.6 Binarization process for part_mode

Inputs to this process are a request for a binarization for the syntax element part_mode, a luma location (xCb, yCb), specifying the top-left sample of the current luma coding block relative to the top-left luma sample of the current picture, a variable log2CbSize specifying the current luma coding block size, and the variable partPredIdc indicating a reference partition mode.

Output of this process is the binarization of the syntax element.

The binarization for the syntax element part_mode is specified in Table I.16 depending on the values of CuPredMode[xCb][yCb], log2CbSize, and partPredIdc.

Table I.16 – Binarization for part_mode

	part_mode	partPredIdc	PartMode	Bin string
--	-----------	-------------	----------	------------

CuPredMode [xCb][yCb]				log2CbSize == MinCbLog2SizeY			
				0		1	
				amp_enabled_flag		log2CbSize > 3	
				0	1	0	1
MODE_INTRA	0	0	PART_2Nx2N	-	-	1	1
	1	0	PART_NxN	-	-	0	0
MODE_INTER	0	0, 1, 2	PART_2Nx2N	1	1	1	1
	1	0	PART_2NxN	01	011	01	01
	2	0	PART_Nx2N	00	001	00	001
	3	0	PART_NxN	-	-	-	000
	4	0	PART_2NxN	-	0100	-	-
	5	0	PART_2NxN	-	0101	-	-
	6	0	PART_nLx2N	-	0000	-	-
	7	0	PART_nRx2N	-	0001	-	-
	1	1	PART_2NxN	0	01	0	0
	2	1	PART_2NxN	-	000	-	-
	3	1	PART_2NxN	-	001	-	-
	1	2	PART_Nx2N	0	01	0	0
	2	2	PART_nLx2N	-	000	-	-
	3	2	PART_nRx2N	-	001	-	-

I.9.3.3.7 Binarization process for intra_chroma_pred_mode

The specifications in clause 9.3.3.8 apply.

I.9.3.3.8 Binarization process for inter_pred_idc

The specifications in clause 9.3.3.9 apply.

I.9.3.3.9 Binarization process for cu_qp_delta_abs

The specifications in clause 9.3.3.10 apply.

I.9.3.3.10 Binarization process for coeff_abs_level_remaining[]

The specifications in clause 9.3.3.11 apply.

I.9.3.3.11 Binarization process for depth_dc_abs

Input to this process is a request for a binarization for the syntax element depth_dc_abs.

Output of this process is the binarization of the syntax element.

The binarization of the syntax element depth_dc_abs is a concatenation of a prefix bin string and (when present) a suffix bin string.

For the derivation of the prefix bin string, the following applies:

- The prefix value of depth_dc_abs, prefixVal, is derived as follows:

$$\text{prefixVal} = \text{Min}(\text{depth_dc_abs}, 3) \quad (\text{I-313})$$

- The prefix bin string is specified by invoking the TR binarization process as specified in clause 9.3.3.2 for prefixVal with cMax = 3 and cRiceParam = 0.

When prefixVal is greater than 2, the suffix bin string is present and it is derived as follows:

- The suffix value of depth_dc_abs, suffixVal, is derived as follows:

$$\text{suffixVal} = \text{depth_dc_abs} - 3 \quad (\text{I-314})$$

- The suffix bin string is specified by invoking the k-th order EGk binarization process as specified in clause 9.3.3.3 for suffixVal with the Exp-Golomb order k set equal to 0.

I.9.3.4 Decoding process flow

I.9.3.4.1 General

The specifications in clause 9.3.4.1 apply with the following modifications.

- All references to the process specified in clause 9.3.3 are replaced with references to the process specified in clause I.9.3.3.
- All invocations of the process specified in clause 9.3.4.2 are replaced with invocations of the process specified in clause I.9.3.4.2.
- All invocations of the process specified in clause 9.3.4.3 are replaced with invocations of the process specified in clause I.9.3.4.3.

I.9.3.4.2 Derivation process for ctxTable, ctxIdx and bypassFlag

I.9.3.4.2.1 General

The specifications in clause 9.3.4.2.1 apply with the following modifications:

- All references to the process specified in clause 9.3.4.2.2 are replaced by references to the process specified in clause I.9.3.4.2.2.
- Table I.17 is appended to the end of Table 9-48.

Table I.17 – Assignment of ctxInc to syntax elements with context coded bins

Syntax element	binIdx					
	0	1	2	3	4	>= 5
skip_intra_flag	0	na	na	na	na	na
no_dim_flag	0	na	na	na	na	na
depth_intra_mode_idx_flag	0	na	na	na	na	na
wedge_full_tab_idx	bypass	bypass	bypass	bypass	bypass	bypass
skip_intra_mode_idx	0	bypass	bypass	na	na	na
dbbp_flag	0	na	na	na	na	na
dc_only_flag	0	na	na	na	na	na
iv_res_pred_weight_idx	0, 1 (clause I.9.3.4.2.2)	2	na	na	na	na
illu_comp_flag	0	na	na	na	na	na
depth_dc_present_flag	0	na	na	na	na	na
depth_dc_abs	0	0	0	bypass	bypass	bypass
depth_dc_sign_flag	bypass	0	0	0	0	0

I.9.3.4.2.2 Derivation process of ctxInc using left and above syntax elements

The specifications in clause 9.3.4.2.2 apply with the following modifications and additions:

- Table I.18 is appended to the end of Table 9-49.

Table I.18 – Specification of ctxInc using left and above syntax elements

Syntax element	condL	condA	ctxInc
iv_res_pred_weight_idx[x0][x0]	iv_res_pred_weight_idx[xNbL][yNbL]		(condL && availableL)

- The assignment of ctxInc for the syntax elements iv_res_pred_weight_idx[x0][y0] is specified in Table 9-49.

I.9.3.4.2.3 Derivation process of ctxInc for the syntax elements last_sig_coeff_x_prefix and last_sig_coeff_y_prefix

The specifications in clause 9.3.4.2.3 apply.

I.9.3.4.2.4 Derivation process of ctxInc for the syntax element coded_sub_block_flag

The specifications in clause 9.3.4.2.4 apply.

I.9.3.4.2.5 Derivation process of ctxInc for the syntax element sig_coeff_flag

The specifications in clause 9.3.4.2.5 apply.

I.9.3.4.2.6 Derivation process of ctxInc for the syntax element coeff_abs_level_greater1_flag

The specifications in clause 9.3.4.2.6 apply.

I.9.3.4.2.7 Derivation process of ctxInc for the syntax element coeff_abs_level_greater2_flag

The specifications in clause 9.3.4.2.7 apply.

I.9.3.4.3 Arithmetic decoding process

The specifications in clause 9.3.4.3 and all its subclauses apply with the following modifications:

- All references to the process specified in clause 9.3.4.2 are replaced with references to the process specified in clause I.9.3.4.2.

I.9.3.5 Arithmetic encoding process (informative)

The specifications in clause 9.3.5 and all its subclauses apply with the following modifications:

- All references to the process specified in clause 9.3.4.3 are replaced with references to the process specified in clause I.9.3.4.3.

I.10 Specification of bitstream subsets

The specifications in clause G.10 apply.

I.11 Profiles, tiers, and levels

I.11.1 Profiles

I.11.1.1 3D Main profile

For a layer in an output operation point associated with an OLS in a bitstream, the layer being conforming to the 3D Main profile, the following applies:

- Let olsIdx be the OLS index of the OLS, the sub-bitstream subBitstream and the base layer sub-bitstream baseBitstream are derived as specified in clause F.11.3.

When vps_base_layer_internal_flag is equal to 1, the base layer sub-bitstream baseBitstream shall obey the following constraints:

- The base layer sub-bitstream baseBitstream shall be indicated to conform to the Main profile.

The sub-bitstream subBitstream shall obey the following constraints:

- All active VPSs shall have vps_num_rep_formats_minus1 in the range of 0 to 15, inclusive.
- All active SPSs for a layer with nuh_layer_id equal to i and DepthLayerFlag[i] equal to 0 in subBitstream shall have chroma_format_idc equal to 1 only.
- All active SPSs for a layer with nuh_layer_id equal to i and DepthLayerFlag[i] equal to 1 in subBitstream shall have chroma_format_idc equal to 0 only.
- All active SPSs for layers in subBitstream shall have transform_skip_rotation_enabled_flag, transform_skip_context_enabled_flag, implicit_rdpem_enabled_flag, explicit_rdpem_enabled_flag, extended_precision_processing_flag, intra_smoothing_disabled_flag, high_precision_offsets_enabled_flag, persistent_rice_adaptation_enabled_flag, and cabac_bypass_alignment_enabled_flag, when present, equal to 0 only.
- CtbLog2SizeY derived from all active SPSs for layers in subBitstream shall be in the range of 4 to 6, inclusive.
- All active PPSs for layers in subBitstream shall have log2_max_transform_skip_block_size_minus2 and chroma_qp_offset_list_enabled_flag, when present, equal to 0 only.
- ScalabilityId[j][smIdx] derived according to any active VPS shall be equal to 0 for any smIdx value not equal to 0 or 1 and for any value of j such that layer_id_in_nuh[j] is among layerIdListTarget that was used to derive subBitstream.

- All active VPSs shall have `alt_output_layer_flag[olsIdx]` equal to 0 only.
- When `ViewOrderIdx[i]` or `DepthLayerFlag[i]` derived according to any active VPS is greater than 0 for the layer with `nuh_layer_id` equal to `i` in `subBitstream`, `num_ref_loc_offsets` shall be equal to 0 in each active PPS for that layer.
- When `ViewOrderIdx[i]` or `DepthLayerFlag[i]` derived according to any active VPS is greater than 0 for the layer with `nuh_layer_id` equal to `i` in `subBitstream`, the values of `pic_width_in_luma_samples` and `pic_height_in_luma_samples` in each active SPS for that layer shall be equal to the values of `pic_width_in_luma_samples` and `pic_height_in_luma_samples`, respectively, in each active SPS for all reference layers of that layer.
- For a layer with `nuh_layer_id` `iNuhLId` equal to any value included in `layerIdListTarget` that was used to derive `subBitstream`, the value of `NumRefLayers[iNuhLId]`, which specifies the total number of direct and indirect reference layers and is derived as specified in F.7.4.3.1, shall be less than or equal to 9.
- All active SPSs for layers in `subBitstream` shall have `sps_range_extension_flag` and `sps_scc_extension_flag` equal to 0 only.
- All active PPSs for layers in `subBitstream` shall have `pps_range_extension_flag` and `pps_scc_extension_flag` equal to 0 only.
- All active SPSs for layers in `subBitstream` shall have `bit_depth_luma_minus8` equal to 0 only.
- All active SPSs for layers in `subBitstream` shall have `bit_depth_chroma_minus8` equal to 0 only.
- All active PPSs for layers in `subBitstream` shall have `colour_mapping_enabled_flag` equal to 0 only.
- When an active PPS for any layer in `subBitstream` has `tiles_enabled_flag` equal to 1, it shall have `entropy_coding_sync_enabled_flag` equal to 0.
- When an active PPS for any layer in `subBitstream` has `tiles_enabled_flag` equal to 1, `ColumnWidthInLumaSamples[i]` shall be greater than or equal to 256 for all values of `i` in the range of 0 to `num_tile_columns_minus1`, inclusive, and `RowHeightInLumaSamples[j]` shall be greater than or equal to 64 for all values of `j` in the range of 0 to `num_tile_rows_minus1`, inclusive.
- The number of times `read_bits(1)` is called in clauses 9.3.4.3.3 and 9.3.4.3.4 when parsing `coding_tree_unit()` data for any CTU shall be less than or equal to $5 * \text{RawCtuBits} / 3$.
- `general_level_idc` and `sub_layer_level_idc[i]` for all values of `i` in active SPSs for any layer in `subBitstream` shall not be equal to 255 (which indicates level 8.5).
- The tier and level constraints specified for the 3D Main profile in clause I.11.2 shall be fulfilled.
- For any active VPS, `ViewOrderIdx[i]` shall be greater than `ViewOrderIdx[j]` for any values of `i` and `j` among `layerIdListTarget` that was used to derive `subBitstream` such that `DepthLayerFlag[i]` is equal to `DepthLayerFlag[j]` and `i` is greater than `j`.
- For any active VPS, `LayerIdxInVps[i]` shall be equal to `LayerIdxInVps[j] + 1` for any values of `i` and `j` among `layerIdListTarget` that was used to derive `subBitstream` such that `ViewOrderIdx[i]` is equal to `ViewOrderIdx[j]`, `DepthLayerFlag[i]` is equal to 1, and `DepthLayerFlag[j]` is equal to 0.

In the remainder of this clause and clause I.11.2, all syntax elements in the `profile_tier_level()` syntax structure refer to those in the `profile_tier_level()` syntax structure associated with the layer.

Conformance of a layer in an output operation point associated with an OLS in a bitstream to the 3D Main profile is indicated as follows:

- If `OpTid` of the output operation point is equal to `vps_max_sub_layer_minus1`, the conformance is indicated by `general_profile_idc` being equal to 8 or `general_profile_compatibility_flag[8]` being equal to 1, and `general_max_12bit_constraint_flag` being equal to 1, `general_max_10bit_constraint_flag` being equal to 1, `general_max_8bit_constraint_flag` being equal to 1, `general_max_422chroma_constraint_flag` being equal to 1, `general_max_420chroma_constraint_flag` being equal to 1, `general_max_monochrome_constraint_flag` being equal to 0, `general_intra_constraint_flag` being equal to 0, and `general_one_picture_only_constraint_flag` being equal to 0, and `general_lower_bit_rate_constraint_flag` being equal to 1.
- Otherwise (`OpTid` of the output operation point is less than `vps_max_sub_layer_minus1`), the conformance is indicated by `sub_layer_profile_idc[OpTid]` being equal to 8 or `sub_layer_profile_compatibility_flag[OpTid][8]` being equal to 1, and `sub_layer_max_12bit_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_10bit_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_8bit_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_422chroma_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_420chroma_constraint_flag[OpTid]` being equal to 1, `sub_layer_max_monochrome_constraint_flag[OpTid]` being equal to 0, `sub_layer_intra_constraint_flag[OpTid]` being equal to 0, and `sub_layer_one_picture_only_constraint_flag[OpTid]` being equal to 0, and `sub_layer_lower_bit_rate_constraint_flag[OpTid]` being equal to 1.

sub_layer_max_monochrome_constraint_flag[OpTid] being equal to 0, sub_layer_intra_constraint_flag[OpTid] being equal to 0, and sub_layer_one_picture_only_constraint_flag[OpTid] being equal to 0, and sub_layer_lower_bit_rate_constraint_flag[OpTid] being equal to 1.

I.11.2 Tiers and levels

The specification in sub-clause G.11.2 and its sub-clauses apply with the following modifications:

- "Multiview Main profile" is replaced by "3D Main profile"

I.11.3 Decoder capabilities

When a decoder conforms to any profile specified in Annex I, it shall also have the INBLD capability specified in clause F.11.1.

Clause F.11.2 specifies requirements for a decoder conforming to any profile specified in Annex I.

I.12 Byte stream format

The specifications in clause G.12 apply.

I.13 Hypothetical reference decoder

The specifications in clause G.13 apply.

I.14 Supplemental enhancement information

I.14.1 General

The specifications in clause G.14.1 apply.

I.14.2 SEI payload syntax

I.14.2.1 General SEI payload syntax

The specifications in clause G.14.2.1 apply.

I.14.2.2 Annex D, Annex F, and Annex G SEI message syntax for 3D high efficiency video coding

The specifications in clauses G.14.2.2 through G.14.2.7 apply.

I.14.2.3 Alternative depth information SEI message syntax

alternative_depth_info(payloadSize) {	Descriptor

I.14.3 SEI payload semantics

I.14.3.1 General SEI payload semantics

The specifications in clause G.14.3.1 apply with the following modifications and additions:

The list VclAssociatedSeiList is set to consist of the payloadType values 2, 3, 6, 9, 15, 16, 17, 19, 22, 23, 45, 47, 56, 128, 131, 132, 134 to 152, inclusive, 154 to 159, inclusive, 161, 165, 167, 168, 177, 178, 179, 200 to 202, inclusive, and 205.

The list PicUnitRepConSeiList is set to consist of the payloadType values 0, 1, 2, 6, 9, 15, 16, 17, 19, 22, 23, 45, 47, 56, 128, 129, 131, 132, 133, 135 to 152, inclusive, 154 to 168, inclusive, 176 to 181, inclusive, 200 to 202, inclusive, and 205.

The semantics and persistence scope for each SEI message specified in this annex are specified in the semantics specification for each particular SEI message in the subclauses of this clause.

NOTE – Persistence information for SEI messages specified in this annex is informatively summarized in Table I.19.

Table I.19 – Persistence scope of SEI messages (informative)

SEI message	Persistence scope
Alternative depth information	Specified by the semantics of the SEI message

I.14.3.2 Annex D, Annex F, and Annex G SEI message semantics for 3D high efficiency video coding

I.14.3.2.1 General

The specifications of clause G.14.3.2 and its subclauses apply with the modifications specified in clause I.14.3.2.2.

I.14.3.2.2 Scalable nesting SEI message semantics for 3D high efficiency video coding

The specifications of clause G.14.3.2.2 apply with the following additions:

An SEI message that has payloadType equal to 181 (Alternative depth information) shall not be directly contained in a scalable nesting SEI message.

I.14.3.3 Alternative depth information SEI message semantics

The alternative depth information SEI message indicates that the decoded depth samples are interpreted as being of an alternative depth format. To discriminate different alternative depth formats, the depth_type syntax element is used.

Let currPic be a picture in the current access unit containing the alpha channel information SEI message. The information of the alternative depth information SEI message persists in output order until any of the following are true:

- A new CVS begins.
- The bitstream ends.
- A picture picB in an access unit containing an alternative depth information SEI message is output having PicOrderCnt(picB) greater than PicOrderCnt(currPic), where PicOrderCnt(picB) and PicOrderCnt(currPic) are the PicOrderCntVal values of picB and currPic, respectively, immediately after the invocation of the decoding process

for picture order count for picB.

alternative_depth_info_cancel_flag equal to 1 indicates that the SEI message cancels the persistence of any previous alternative depth information SEI message in output order. **alternative_depth_info_cancel_flag** equal to 0 indicates that alternative depth information follows.

depth_type identifies an alternative depth type according to Table I.20. **depth_type** equal to 0 indicates that global view and depth (GVD) information is present in this SEI message. **depth_type** equal to 1 indicates that the decoded depth samples can be used to derive a warp map and view synthesis can be performed by image-domain warping. Values of **depth_type** that are not listed in Table I.20 are reserved for future use by ITU-T | ISO/IEC and shall not be present in bitstreams conforming to this version of this Specification. Decoders shall ignore alternative depth information SEI messages that contain reserved values of **depth_type**.

Table I.20 – Interpretation of depth_type

Value	Description
0	Global view and depth (GVD)
1	Warp map

When the SEI message signals GVD information, the pictures of a view with ViewIdx greater than 0 contain samples of multiple subsampled pictures (subsequently denoted as constituent pictures), which are located in a spatial packing arrangement. This GVD information can be used after the decoder output to appropriately rearrange the samples in order to produce additional views that are appropriate for display or other purposes (which are outside the scope of this Recommendation | International Standard).

Layers that are referred to by this GVD information shall conform to the Main Profile, the Multiview Main profile, or the 3D Main profile, as specified in Annexes A, G, and I, respectively. The depth representation type is defined in the depth representation information SEI message that shall be always present together with the GVD information.

When the CVS contains an alternative depth information SEI message with **depth_type** equal to 0, and the first access unit in the CVS is an IRAP access unit, there shall be an alternative depth information SEI message with **depth_type** equal to 0 in the first access unit of the CVS. When GVD information is present, the following applies:

- The CVS shall represent two views.
- A texture layer and a depth layer shall both be present for the view with ViewIdx equal to 0.
- A texture layer shall be present and a depth layer may be present for the view with ViewIdx greater than 0.
- The value of NumDirectRefLayers[LayerIdxInVps[depLayerId]] shall be equal to 0 for any value of depLayerId among nuh_layer_id values of layers of the view with ViewIdx equal to 0 or the view with ViewIdx greater than 0.
- The pictures of the view with ViewIdx equal to 0 shall represent full resolution pictures.
- Each picture of the view with ViewIdx greater than 0 shall contain a packing arrangement of 1 to 4 sub-sampled pictures of constituent views. Such sub-sampled pictures are denoted as constituent pictures.
- All constituent pictures shall have a width and a height equal to $(\text{pic_width_in_luma_samples} / 2)$ and $(\text{pic_height_in_luma_samples} / 2)$ in luma samples, respectively.

The variable *i* (with a value in the range of 1 to num_constituent_views_minus1 + 1, inclusive) in the alternative_depth_info() syntax structure is an index that is associated with the location of the constituent picture in the picture of the view with ViewIdx greater than 0, as specified in Table I.21. With regard to the remaining syntax elements in the alternative_depth_info() syntax structure, *i* equal to 0 refers to the parameters of the view with ViewIdx equal to 0 and *i* greater than 0 refers to the parameter of one of the constituent views.

NOTE 1 – The ViewIdx of the view with ViewIdx greater than 0 is not used for identification of constituent views in the context of this SEI message, but the variable *i*.

Table I.21 – Locations of the top-left luma samples of constituent pictures packed in a picture with ViewIdx greater than 0 relative to the top-left luma sample of this picture

Constituent picture index <i>i</i>	Location of the top-left luma sample in a picture with ViewIdx greater than 0
1	(0, 0)
2	(0, pic_height_in_luma_samples / 2)

3	(pic_width_in_luma_samples / 2, 0)
4	(pic_width_in_luma_samples / 2, pic_height_in_luma_samples / 2)

num_constituent_views_gvd_minus1 plus 1 specifies the number of constituent pictures packed into each picture of the view with ViewIdx greater than 0. num_constituent_views_gvd_minus1 shall be in the range of 0 to 3, inclusive.

depth_present_gvd_flag equal to 1 specifies that the depth layer for the view with ViewIdx greater than 0 is present and contains constituent pictures with a packing arrangement as described above. depth_present_gvd_flag equal to 0 specifies that the depth layer for the view with ViewIdx greater than 0 is not present.

Each constituent picture of a depth layer for the view with ViewIdx greater than 0 is associated with a constituent picture of the texture layer for the view with ViewIdx greater than 0 in the same relative location.

NOTE 2 – The following SEI message parameters can be used along with the decoded pictures of the depth layers to project samples from the view with ViewIdx equal to 0 into the co-ordinates of constituent views such that the reconstructed views can be generated by combining the projected samples and the samples from the constituent views.

The function binToFp(s, e, n, v) is specified as follows:

$$\text{binToFp}(s, e, n, v) = (-1)^s * (e == 0 ? (2^{-(30+v)} * n) : (2^{e-31} * (1 + n \div 2^v))) \quad (\text{I-315})$$

NOTE 3 – The above specification is similar to what is found in IEC 60559:1989.

z_gvd_flag equal to 1 indicates the presence of the syntax elements sign_gvd_z_near_flag[i], exp_gvd_z_near[i], man_len_gvd_z_near_minus1[i], man_gvd_z_near[i], sign_gvd_z_far_flag[i], exp_gvd_z_far[i], man_len_gvd_z_far_minus1[i], and man_gvd_z_far[i], for i in the range of 0 to num_constituent_views_minus1 + 1, inclusive. z_gvd_flag equal to 0 indicates that these syntax elements are not present.

intrinsic_param_gvd_flag equal to 1 indicates the presence of intrinsic camera parameter syntax elements. intrinsic_param_gvd_flag equal to 0 indicates that these syntax elements are not present.

rotation_gvd_flag equal to 1 indicates the presence of rotation camera parameter syntax elements. rotation_gvd_flag equal to 0 indicates that these syntax elements are not present. When rotation_gvd_flag is equal to 0, a default rotation camera parameter of a unit matrix value is inferred.

translation_gvd_flag equal to 1 indicates the presence of horizontal translation camera parameter syntax elements. translation_gvd_flag equal to 0 indicates that these syntax elements are not present.

sign_gvd_z_near_flag[i] equal to 0 indicates that the sign of the nearest depth value of the i-th camera is positive. sign_gvd_z_near_flag[i] equal to 1 indicates that the sign of the nearest depth value of the i-th camera is negative.

exp_gvd_z_near[i] specifies the exponent part of the nearest depth value of the i-th camera. The value of exp_gvd_z_near[i] shall be in the range of 0 to 126, inclusive. The value 127 is reserved for future use by ITU-T | ISO/IEC. When exp_gvd_z_near[i] is equal to 127, the value of zNear[i] is unspecified.

man_len_gvd_z_near_minus1[i] plus 1 specifies the length in bits of the mantissa of the nearest depth value of the i-th camera. The value of man_len_gvd_z_near_minus1[i] shall be in the range of 0 to 31, inclusive.

man_gvd_z_near[i] specifies the mantissa part of the nearest depth value of the i-th camera. The length of man_gvd_z_near[i] syntax elements is man_len_gvd_z_near_minus1[i] + 1 bits.

When exp_gvd_z_near[i] is not equal to 127, zNear[i] is set equal to binToFp(sign_gvd_z_near_flag[i], exp_gvd_z_near[i], man_gvd_z_near[i], man_len_gvd_z_near_minus1[i] + 1).

sign_gvd_z_far_flag[i] equal to 0 indicates that the sign of the farthest depth value of the i-th camera is positive. sign_gvd_z_far_flag[i] equal to 1 indicates that the sign of the farthest depth value of the i-th camera is negative.

exp_gvd_z_far[i] specifies the exponent part of the farthest depth value of the i-th camera. The value of exp_gvd_z_far[i] shall be in the range of 0 to 126, inclusive. The value 127 is reserved for future use by ITU-T | ISO/IEC. When exp_gvd_z_far[i] is equal to 127, the value of zFar[i] is unspecified.

man_len_gvd_z_far_minus1[i] plus 1 specifies the length in bits of the mantissa of the farthest depth value of the i-th camera. The value of man_len_gvd_z_far_minus1[i] shall be in the range of 0 to 31, inclusive.

man_gvd_z_far[i] specifies the mantissa part of the farthest depth value of the i-th camera. The length of man_gvd_z_far[i] syntax elements is man_len_gvd_z_far_minus1[i] + 1 bits.

When exp_gvd_z_far[i] is not equal to 127, zFar[i] is set equal to binToFp(sign_gvd_z_far_flag[i], exp_gvd_z_far[i], man_gvd_z_far[i], man_len_gvd_z_far_minus1[i] + 1).

prec_gvd_focal_length specifies the exponent of the maximum allowable truncation error for focalLengthX[i] and

focalLengthY[i] as given by $2^{-\text{prec_gvd_focal_length}}$. The value of prec_gvd_focal_length shall be in the range of 0 to 31, inclusive.

prec_gvd_principal_point specifies the exponent of the maximum allowable truncation error for principalPointX[i] and principalPointY[i] as given by $2^{-\text{prec_gvd_principal_point}}$. The value of prec_gvd_principal_point shall be in the range of 0 to 31, inclusive.

prec_gvd_rotation_param specifies the exponent of the maximum allowable truncation error for $r[i][j][k]$ as given by $2^{-\text{prec_gvd_rotation_param}}$. The value of prec_gvd_rotation_param shall be in the range of 0 to 31, inclusive.

prec_gvd_translation_param specifies the exponent of the maximum allowable truncation error for $tX[i]$ as given by $2^{-\text{prec_gvd_translation_param}}$. The value of prec_gvd_translation_param shall be in the range of 0 to 31, inclusive.

sign_gvd_focal_length_x[i] equal to 0 indicates that the sign of the focal length of the i-th camera in the horizontal direction is positive. sign_gvd_focal_length_x[i] equal to 1 indicates that the sign of the focal length of the i-th camera in the horizontal direction is negative.

exp_gvd_focal_length_x[i] specifies the exponent part of the focal length of the i-th camera in the horizontal direction. The value of exp_gvd_focal_length_x[i] shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. When exp_gvd_focal_length_x[i] is equal to 63, the value of focal length of the horizontal direction for the i-th camera is unspecified.

man_gvd_focal_length_x[i] specifies the mantissa part of the focal length of the i-th camera in the horizontal direction. The length v of the man_gvd_focal_length_x[i] syntax element is determined as follows:

- If exp_gvd_focal_length_x[i] is equal to 0, the length v is set equal to $\text{Max}(0, \text{prec_gvd_focal_length} - 30)$.
- Otherwise (exp_gvd_focal_length_x[i] is in the range of 1 to 62, inclusive), the length v is $\text{Max}(0, \text{exp_gvd_focal_length_x}[i] + \text{prec_gvd_focal_length} - 31)$.

When exp_gvd_focal_length_x[i] is not equal to 63, the variable focalLengthX[i] is set equal to $\text{binToFp}(\text{sign_gvd_focal_length_x}[i], \text{exp_gvd_focal_length_x}[i], \text{man_gvd_focal_length_x}[i], v)$.

sign_gvd_focal_length_y[i] equal to 0 indicates that the sign of the focal length of the i-th camera in the vertical direction is positive. sign_gvd_focal_length_y[i] equal to 1 indicates that the sign of the focal length of the i-th camera in the vertical direction is negative.

exp_gvd_focal_length_y[i] specifies the exponent part of the focal length of the i-th camera in the vertical direction. The value of exp_gvd_focal_length_y[i] shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. When exp_gvd_focal_length_y[i] is equal to 63, the value of focal length of the vertical direction is unspecified.

man_gvd_focal_length_y[i] specifies the mantissa part of the focal length of the i-th camera in the vertical direction.

The length v of the man_gvd_focal_length_y[i] syntax element is determined as follows:

- If exp_gvd_focal_length_y[i] is equal to 0, the length v is set equal to $\text{Max}(0, \text{prec_gvd_focal_length} - 30)$.
- Otherwise (exp_gvd_focal_length_y[i] is in the range of 1 to 62, inclusive), the length v is set equal to $\text{Max}(0, \text{exp_gvd_focal_length_y}[i] + \text{prec_gvd_focal_length} - 31)$.

When exp_gvd_focal_length_y[i] is not equal to 63, the variable focalLengthY[i] is set equal to $\text{binToFp}(\text{sign_gvd_focal_length_y}[i], \text{exp_gvd_focal_length_y}[i], \text{man_gvd_focal_length_y}[i], v)$.

sign_gvd_principal_point_x[i] equal to 0 indicates that the sign of the principal point of the i-th camera in the horizontal direction is positive. sign_gvd_principal_point_x[i] equal to 1 indicates that the sign of the principal point of the i-th camera in the horizontal direction is negative.

exp_gvd_principal_point_x[i] specifies the exponent part of the principal point of the i-th camera in the horizontal direction. The value of exp_gvd_principal_point_x[i] shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. When exp_gvd_principal_point_x[i] is equal to 63, the value of principal point in the horizontal direction for the i-th camera is unspecified.

man_gvd_principal_point_x[i] specifies the mantissa part of the principal point of the i-th camera in the horizontal direction. The length v of the man_gvd_principal_point_x[i] syntax element in units of bits is determined as follows:

- If exp_gvd_principal_point_x[i] is equal to 0, the length v is set equal to $\text{Max}(0, \text{prec_gvd_principal_point} - 30)$.
- Otherwise (exp_gvd_principal_point_x[i] is in the range of 1 to 62, inclusive), the length v is set equal to $\text{Max}(0, \text{exp_gvd_principal_point_x}[i] + \text{prec_gvd_principal_point} - 31)$.

When exp_gvd_principal_point_x[i] is not equal to 63, the variable principalPointX[i] is set equal to

$\text{binToFp}(\text{sign_gvd_principal_point_x}[i], \text{exp_gvd_principal_point_x}[i], \text{man_gvd_principal_point_x}[i], v)$.

sign_gvd_principal_point_y[i] equal to 0 indicates that the sign of the principal point of the i-th camera in the vertical direction is positive. **sign_gvd_principal_point_y[i]** equal to 1 indicates that the sign of the principal point of the i-th camera in the vertical direction is negative.

exp_gvd_principal_point_y[i] specifies the exponent part of the principal point of the i-th camera in the vertical direction. The value of **exp_gvd_principal_point_y[i]** shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. When **exp_gvd_principal_point_y[i]** is equal to 63, the value of principal point in the vertical direction for the i-th camera is unspecified.

man_gvd_principal_point_y[i] specifies the mantissa part of the principal point of the i-th camera in the vertical direction. The length v of the **man_gvd_principal_point_y[i]** syntax element in units of bits is determined as follows:

- If **exp_gvd_principal_point_y[i]** is equal to 0, the length v is set equal to $\text{Max}(0, \text{prec_gvd_principal_point} - 30)$.
- Otherwise (**exp_gvd_principal_point_y[i]** is in the range of 1 to 62, inclusive), the length v is set equal to $\text{Max}(0, \text{exp_gvd_principal_point_y}[i] + \text{prec_gvd_principal_point} - 31)$.

When **exp_gvd_principal_point_y[i]** is not equal to 63, the variable **principalPointY[i]** is set equal to $\text{binToFp}(\text{sign_gvd_principal_point_y}[i], \text{exp_gvd_principal_point_y}[i], \text{man_gvd_principal_point_y}[i], v)$.

sign_gvd_r[i][j][k] equal to 0 indicates that the sign of (j, k) component of the rotation matrix for the i-th camera is positive. **sign_gvd_r[i][j][k]** equal to 1 indicates that the sign of (j, k) component of the rotation matrix for the i-th camera is negative.

exp_gvd_r[i][j][k] specifies the exponent part of (j, k) component of the rotation matrix for the i-th camera. The value of **exp_gvd_r[i][j][k]** shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. When **exp_gvd_r[i][j][k]** is equal to 63, the value of rotation matrix is unspecified.

man_gvd_r[i][j][k] specifies the mantissa part of (j, k) component of the rotation matrix for the i-th camera.

The length v of the **man_gvd_r[i][j][k]** syntax element in units of bits is determined as follows:

- If **exp_gvd_r[i]** is equal to 0, the length v is set equal to $\text{Max}(0, \text{prec_gvd_rotation_param} - 30)$.
- Otherwise (**exp_gvd_r[i]** is in the range of 1 to 62, inclusive), the length v is set equal to $\text{Max}(0, \text{exp_gvd_r}[i] + \text{prec_gvd_rotation_param} - 31)$.

When **exp_gvd_r[i][j][k]** is not equal to 63, the variable **r[i][j][k]** is set equal to $\text{binToFp}(\text{sign_gvd_r}[i][j][k], \text{exp_gvd_r}[i][j][k], \text{man_gvd_r}[i][j][k], v)$.

The rotation matrix $R[i]$ for i-th camera is represented as follows:

$$\begin{bmatrix} r[i][0][0] & r[i][0][1] & r[i][0][2] \\ r[i][1][0] & r[i][1][1] & r[i][1][2] \\ r[i][2][0] & r[i][2][1] & r[i][2][2] \end{bmatrix} \quad (\text{I-316})$$

sign_gvd_t_x[i] equal to 0 indicates that the sign of the horizontal component of the translation vector for the i-th camera is positive. **sign_gvd_t_x[i]** equal to 1 indicates that the sign of the horizontal component of the translation vector for the i-th camera is negative.

exp_gvd_t_x[i] specifies the exponent part of the horizontal component of the translation vector for the i-th camera. The value of **exp_gvd_t_x[i]** shall be in the range of 0 to 62, inclusive. The value 63 is reserved for future use by ITU-T | ISO/IEC. When **exp_gvd_t_x[i]** is equal to 63, the value of the translation vector is unspecified.

man_gvd_t_x[i] specifies the mantissa part of the horizontal component of the translation vector for the i-th camera.

The length v of the **man_gvd_t_x[i]** syntax element in units of bits is determined as follows:

- If **exp_gvd_t_x[i]** is equal to 0, the length v is set equal to $\text{Max}(0, \text{prec_gvd_translation_param} - 30)$.
- Otherwise (**exp_gvd_t_x[i]** is in the range of 1 to 62, inclusive), the length v is set equal to $\text{Max}(0, \text{exp_gvd_t_x}[i] + \text{prec_gvd_translation_param} - 31)$.

When **exp_gvd_t_x[i]** is not equal to 63, the variable **tX[i]** is set equal to $\text{binToFp}(\text{sign_gvd_t_x}[i], \text{exp_gvd_t_x}[i], \text{man_gvd_t_x}[i], v)$.

When the SEI signals warp map information, syntax elements of this SEI can be used to derive a sparse set of positional correspondences between decoded pictures of different views from decoded pictures of depth layers.

min_offset_x_int, min_offset_x_frac specify the integer and the fractional part of the minimum offset for the horizontal direction of a warp map.

The variable minOffsetX is derived as follows:

$$\text{minOffsetX} = \text{min_offset_x_int} + \text{min_offset_x_frac} \div 256 \quad (\text{I-317})$$

max_offset_x_int, max_offset_x_frac specify the integer and the fractional part of the maximum offset for the horizontal direction of a warp map.

The variable maxOffsetX value is derived as follows:

$$\text{maxOffsetX} = \text{max_offset_x_int} + \text{max_offset_x_frac} \div 256 \quad (\text{I-318})$$

offset_y_present_flag equal to 1 specifies that **min_offset_y_int, min_offset_y_frac, max_offset_y_int, and max_offset_y_frac** are present. **offset_y_present_flag** equal to 0 specifies that **min_offset_y_int, min_offset_y_frac, max_offset_y_int, and max_offset_y_frac** are not present.

min_offset_y_int, min_offset_y_frac specify the integer and the fractional part of the minimum offset for the vertical direction of a warp map. When not present, the values of **min_offset_y_int** and **min_offset_y_frac** are inferred to be equal to 0.

The variable minOffsetY value is derived as follows:

$$\text{minOffsetY} = \text{min_offset_y_int} + \text{min_offset_y_frac} \div 256 \quad (\text{I-319})$$

max_offset_y_int, max_offset_y_frac specify the integer and the fractional part of the maximum offset for the vertical direction of a warp map. When not present, the values of **max_offset_y_int** and **max_offset_y_frac** are inferred to be equal to 0.

The variable maxOffsetY value is derived as follows:

$$\text{maxOffsetY} = \text{max_offset_y_int} + \text{max_offset_y_frac} \div 256 \quad (\text{I-320})$$

warp_map_size_present_flag equal to 1 specifies that a new warp map size is present, which is valid for the current and all following warp maps in output order until a new message with **warp_map_size_present_flag** equal to 1 is received or **alternative_depth_info_cancel_flag** is equal to 1. **warp_map_size_present_flag** equal to 0 specifies that the warp map size is not changed.

warp_map_width_minus2 plus 2 specifies the width of the warp map. The value of **warp_map_width_minus2** shall be in the range of 0 to (**pic_width_in_luma_samples** - 2), inclusive. The variable **warpMapWidth** is set equal to (**warp_map_width_minus2** + 2).

warp_map_height_minus2 plus 2 specifies the height of the warp map. The value of **warp_map_height_minus2** shall be in the range of 0 to (**pic_height_in_luma_samples** >> **offset_y_present_flag**) - 2, inclusive. The variable **warpMapHeight** is set equal to (**warp_map_height_minus2** + 2).

The variables **deltaX**, **deltaY**, **scaleX**, and **scaleY** are derived as follows:

$$\text{deltaX} = \text{pic_width_in_luma_samples} \div (\text{warpMapWidth} - 1) \quad (\text{I-321})$$

$$\text{deltaY} = \text{pic_height_in_luma_samples} \div (\text{warpMapHeight} - 1) \quad (\text{I-322})$$

$$\text{scaleX} = (\text{maxOffsetX} - \text{minOffsetX}) / ((1 \ll \text{BitDepth}_Y) - 1) \quad (\text{I-323})$$

$$\text{scaleY} = (\text{maxOffsetY} - \text{minOffsetY}) / ((1 \ll \text{BitDepth}_Y) - 1) \quad (\text{I-324})$$

Let **recSamples[x][y]** correspond to the reconstructed sample array S_L of a picture of a depth layer. The corresponding horizontal warp map component **w[x][y][0]** and the corresponding vertical warp map component **w[x][y][1]** for **recSamples[x][y]** are derived as follows:

```

for( x = 0; x < warpMapWidth; x++ )
    for( y = 0; y < warpMapHeight; y++ ) {
        w[x][y][0] = x * deltaX + minOffsetX + scaleX * recSamples[x][y]
        if( offset_y_present_flag )
            w[x][y][1] = y * deltaY + minOffsetY +
                        scaleY * recSamples[x][y + pic_height_in_luma_samples / 2 ]
        else
            w[x][y][1] = y * deltaY
    }

```

(I-325)

A warp map **w[x][y]** derived using the reconstructed sample array S_L of a picture included in a particular access unit and in a depth layer of a particular view is associated with the pictures included in the particular view and in the particular

access unit. The warp map specifies a sparse set of positional correspondences. These correspondences identify semantically corresponding sample locations between pictures included in the particular view and the particular AU, and the pictures included in a neighbouring view and the particular AU as follows:

- If the warp map $w[x][y]$ is associated with a picture of the leftmost view, the warp map specifies for each location $(x * \text{deltaX}, y * \text{deltaY})$ of this picture a corresponding location $(2 * w[x][y][0], 2 * w[x][y][1])$ in a picture of the closest neighbouring view on the right.
- Otherwise (the warp map $w[x][y]$ is associated with a picture of a view different to the leftmost view), the warp map specifies for each location $(x * \text{deltaX}, y * \text{deltaY})$ in this picture a corresponding location $(2 * w[x][y][0], 2 * w[x][y][1])$ in a picture of the closest neighbouring view on the left.

I.15 Video usability information

The specifications in clause G.15 apply.

SERIES OF ITU-T RECOMMENDATIONS

Series A	Organization of the work of ITU-T
Series D	Tariff and accounting principles and international telecommunication/ICT economic and policy issues
Series E	Overall network operation, telephone service, service operation and human factors
Series F	Non-telephone telecommunication services
Series G	Transmission systems and media, digital systems and networks
Series H	Audiovisual and multimedia systems
Series I	Integrated services digital network
Series J	Cable networks and transmission of television, sound programme and other multimedia signals
Series K	Protection against interference
Series L	Environment and ICTs, climate change, e-waste, energy efficiency; construction, installation and protection of cables and other elements of outside plant
Series M	Telecommunication management, including TMN and network maintenance
Series N	Maintenance: international sound programme and television transmission circuits
Series O	Specifications of measuring equipment
Series P	Telephone transmission quality, telephone installations, local line networks
Series Q	Switching and signalling, and associated measurements and tests
Series R	Telegraph transmission
Series S	Telegraph services terminal equipment
Series T	Terminals for telematic services
Series U	Telegraph switching
Series V	Data communication over the telephone network
Series X	Data networks, open system communications and security
Series Y	Global information infrastructure, Internet protocol aspects, next-generation networks, Internet of Things and smart cities
Series Z	Languages and general software aspects for telecommunication systems

EXHIBIT 4

US007532808B2

(12) **United States Patent**
Lainema

(10) **Patent No.:** **US 7,532,808 B2**
(45) **Date of Patent:** **May 12, 2009**

(54) **METHOD FOR CODING MOTION IN A VIDEO SEQUENCE**

(75) Inventor: **Jani Lainema**, Irving, TX (US)

(73) Assignee: **Nokia Corporation**, Espoo (FI)

(57) **ABSTRACT**

A method of motion-compensated video encoding that enables a video sequence with a global motion component to be encoded in an efficient manner. A video encoder is arranged to assign macroblocks to be coded to specific coding modes including a skip mode, which is used to indicate one of two possible types of macroblock motion: a) zero motion, or b) global or regional motion. As each macroblock is encoded, a previously encoded region surrounding the macroblock is examined and the characteristics of motion in that region determined. With the skip mode, the macroblock to be coded and a motion vector describing the global motion or regional motion is associated with the macroblock if the motion in the region is characteristic of global motion or regional motion. If the region exhibits an insignificant level of motion, a zero valued motion vector is associated with the macroblock.

METHOD FOR CODING MOTION IN A VIDEO SEQUENCE

This application claims the benefit of U.S. Provisional Application No. 60/365,072 filed Mar. 15, 2002.

FIELD OF THE INVENTION

The invention relates generally to communication systems and more particularly to motion compensation in video coding.

BACKGROUND OF THE INVENTION

A digital video sequence, like an ordinary motion picture recorded on film, comprises a sequence of still images, the illusion of motion being created by displaying consecutive images of the sequence one after the other at a relatively fast rate, typically 15 to 30 frames per second. Because of the relatively fast frame display rate, images in consecutive frames tend to be quite similar and thus contain a considerable amount of redundant information. For example, a typical scene may comprise some stationary elements, such as background scenery, and some moving areas, which may take many different forms, for example the face of a newsreader, moving traffic and so on. Alternatively, or additionally, so-called "global motion" may be present in the video sequence, for example due to translation, panning or zooming of the camera recording the scene. However, in many cases, the overall change between one video frame and the next is rather small.

Each frame of an uncompressed digital video sequence comprises an array of image pixels. For example, in a commonly used digital video format, known as the Quarter Common Interchange Format (QCIF), a frame comprises an array of 176×144 pixels, in which case each frame has 25,344 pixels. In turn, each pixel is represented by a certain number of bits, which carry information about the luminance and/or color content of the region of the image corresponding to the pixel. Commonly, a so-called YUV color model is used to represent the luminance and chrominance content of the image. The luminance, or Y, component represents the intensity (brightness) of the image, while the color content of the image is represented by two chrominance or color difference components, labelled U and V.

Color models based on a luminance/chrominance representation of image content provide certain advantages compared with color models that are based on a representation involving primary colors (that is Red, Green and Blue, RGB). The human visual system is more sensitive to intensity variations than it is to color variations and YUV color models exploit this property by using a lower spatial resolution for the chrominance components (U, V) than for the luminance component (Y). In this way, the amount of information needed to code the color information in an image can be reduced with an acceptable reduction in image quality.

The lower spatial resolution of the chrominance components is usually attained by spatial sub-sampling. Typically, each frame of a video sequence is divided into so-called "macroblocks", which comprise luminance (Y) information and associated (spatially sub-sampled) chrominance (U, V) information. FIG. 3 illustrates one way in which macroblocks can be formed. FIG. 3a shows a frame of a video sequence represented using a YUV color model, each component having the same spatial resolution. Macroblocks are formed by representing a region of 16×16 image pixels in the original image (FIG. 3b) as four blocks of luminance information,

2

each luminance block comprising an 8×8 array of luminance (Y) values and two spatially corresponding chrominance components (U and V) which are sub-sampled by a factor of two in the horizontal and vertical directions to yield corresponding arrays of 8×8 chrominance (U, V) values (see FIG. 3c).

A QCIF image comprises 11×9 macroblocks. If the luminance blocks and chrominance blocks are represented with 8 bit resolution (that is by numbers in the range 0 to 255), the total number of bits required per macroblock is $(16 \times 16 \times 8) + 2 \times (8 \times 8 \times 8) = 3072$ bits. The number of bits needed to represent a video frame in QCIF format is thus $99 \times 3072 = 304,128$ bits. This means that the amount of data required to transmit/record/display an uncompressed video sequence in QCIF format, represented using a YUV color model, at a rate of 30 frames per second, is more than 9 Mbps (million bits per second). This is an extremely high data rate and is impractical for use in video recording, transmission and display applications because of the very large storage capacity, transmission channel capacity and hardware performance required.

If video data is to be transmitted in real-time over a fixed line network such as an ISDN (Integrated Services Digital Network) or a conventional PSTN (Public Switched Telephone Network), the available data transmission bandwidth is typically of the order of 64 kbits/s. In mobile videotelephony, where transmission takes place at least in part over a radio communications link, the available bandwidth can be as low as 20 kbits/s. This means that a significant reduction in the amount of information used to represent video data must be achieved in order to enable transmission of digital video sequences over low bandwidth communication networks. For this reason, video compression techniques have been developed which reduce the amount of information transmitted while retaining an acceptable image quality.

Video compression methods are based on reducing the redundant and perceptually irrelevant parts of video sequences. The redundancy in video sequences can be categorised into spatial, temporal and spectral redundancy. "Spatial redundancy" is the term used to describe the correlation (similarity) between neighbouring pixels within a frame. The term "temporal redundancy" expresses the fact that objects appearing in one frame of a sequence are likely to appear in subsequent frames, while "spectral redundancy" refers to the correlation between different color components of the same image.

Sufficiently efficient compression cannot usually be achieved by simply reducing the various forms of redundancy in a given sequence of images. Thus, most current video encoders also reduce the quality of those parts of the video sequence which are subjectively the least important. In addition, the redundancy of the compressed video bit-stream itself is reduced by means of efficient loss-less encoding. Generally, this is achieved using a technique known as entropy coding.

There is often a significant amount of spatial redundancy between the pixels that make up each frame of a digital video sequence. In other words, the value of any pixel within a frame of the sequence is substantially the same as the value of other pixels in its immediate vicinity. Typically, video coding systems reduce spatial redundancy using a technique known as "block-based transform coding", in which a mathematical transformation, such as a two-dimensional Discrete Cosine Transform (DCT), is applied to blocks of image pixels. This transforms the image data from a representation comprising pixel values to a form comprising a set of coefficient values representative of spatial frequency components significantly

reducing spatial redundancy and thereby producing a more compact representation of the image data.

Frames of a video sequence which are compressed using block-based transform coding, without reference to any other frame within the sequence, are referred to as INTRA-coded or I-frames. Additionally, and where possible, blocks of INTRA-coded frames are predicted from previously coded blocks within the same frame. This technique, known as INTRA-prediction, has the effect of further reducing the amount of data required to represent an INTRA-coded frame.

Generally, video coding systems not only reduce the spatial redundancy within individual frames of a video sequence, but also make use of a technique known as "motion-compensated prediction", to reduce the temporal redundancy in the sequence. Using motion-compensated prediction, the image content of some (often many) frames in a digital video sequence is "predicted" from one or more other frames in the sequence, known as "reference" frames. Prediction of image content is achieved by tracking the motion of objects or regions of an image between a frame to be coded (compressed) and the reference frame(s) using "motion vectors". In general, the reference frame(s) may precede the frame to be coded or may follow it in the video sequence. As in the case of INTRA-coding, motion compensated prediction of a video frame is typically performed macroblock-by-macroblock.

Frames of a video sequence which are compressed using motion-compensated prediction are generally referred to as INTER-coded or P-frames. Motion-compensated prediction alone rarely provides a sufficiently precise representation of the image content of a video frame and therefore it is typically necessary to provide a so-called "prediction error" (PE) frame with each INTER-coded frame. The prediction error frame represents the difference between a decoded version of the INTER-coded frame and the image content of the frame to be coded. More specifically, the prediction error frame comprises values that represent the difference between pixel values in the frame to be coded and corresponding reconstructed pixel values formed on the basis of a predicted version of the frame in question. Consequently, the prediction error frame has characteristics similar to a still image and block-based transform coding can be applied in order to reduce its spatial redundancy and hence the amount of data (number of bits) required to represent it.

In order to illustrate the operation of a generic video coding system in greater detail, reference will now be made to the exemplary video encoder and video decoder illustrated in FIGS. 1 and 2 of the accompanying drawings. The video encoder **100** of FIG. 1 employs a combination of INTRA- and INTER-coding to produce a compressed (encoded) video bit-stream and decoder **200** of FIG. 2 is arranged to receive and decode the video bit-stream produced by encoder **100** in order to produce a reconstructed video sequence. Throughout the following description it will be assumed that the luminance component of a macroblock comprises 16x16 pixels arranged as an array of 4, 8x8 blocks, and that the associated chrominance components are spatially sub-sampled by a factor of two in the horizontal and vertical directions to form 8x8 blocks, as depicted in FIG. 3. Extension of the description to other block sizes and other sub-sampling schemes will be apparent to those of ordinary skill in the art.

The video encoder **100** comprises an input **101** for receiving a digital video signal from a camera or other video source (not shown). It also comprises a transformation unit **104** which is arranged to perform a block-based discrete cosine transform (DCT), a quantizer **106**, an inverse quantizer **108**, an inverse transformation unit **110**, arranged to perform an inverse block-based discrete cosine transform (IDCT), com-

biners **112** and **116**, and a frame store **120**. The encoder further comprises a motion estimator **130**, a motion field coder **140** and a motion compensated predictor **150**. Switches **102** and **114** are operated co-operatively by control manager **160** to switch the encoder between an INTRA-mode of video encoding and an INTER-mode of video encoding. The encoder **100** also comprises a video multiplex coder **170** which forms a single bit-stream from the various types of information produced by the encoder **100** for further transmission to a remote receiving terminal or, for example, for storage on a mass storage medium, such as a computer hard drive (not shown).

Encoder **100** operates as follows. Each frame of uncompressed video provided from the video source to input **101** is received and processed macroblock by macroblock, preferably in raster-scan order. When the encoding of a new video sequence starts, the first frame to be encoded is encoded as an INTRA-coded frame. Subsequently, the encoder is programmed to code each frame in INTER-coded format, unless one of the following conditions is met: 1) it is judged that the current macroblock of the frame being coded is so dissimilar from the pixel values in the reference frame used in its prediction that excessive prediction error information is produced, in which case the current macroblock is coded in INTRA-coded format; 2) a predefined INTRA frame repetition interval has expired; or 3) feedback is received from a receiving terminal indicating a request for a frame to be provided in INTRA-coded format.

The occurrence of condition 1) is detected by monitoring the output of the combiner **116**. The combiner **116** forms a difference between the current macroblock of the frame being coded and its prediction, produced in the motion compensated prediction block **150**. If a measure of this difference (for example a sum of absolute differences of pixel values) exceeds a predetermined threshold, the combiner **116** informs the control manager **160** via a control line **119** and the control manager **160** operates the switches **102** and **114** via control line **113** so as to switch the encoder **100** into INTRA-coding mode. In this way, a frame which is otherwise encoded in INTER-coded format may comprise INTRA-coded macroblocks. Occurrence of condition 2) is monitored by means of a timer or frame counter implemented in the control manager **160**, in such a way that if the timer expires, or the frame counter reaches a predetermined number of frames, the control manager **160** operates the switches **102** and **114** via control line **113** to switch the encoder into INTRA-coding mode. Condition 3) is triggered if the control manager **160** receives a feedback signal from, for example, a receiving terminal, via control line **121** indicating that an INTRA frame refresh is required by the receiving terminal. Such a condition may arise, for example, if a previously transmitted frame is badly corrupted by interference during its transmission, rendering it impossible to decode at the receiver. In this situation, the receiving decoder issues a request for the next frame to be encoded in INTRA-coded format, thus re-initialising the coding sequence.

Operation of the encoder **100** in INTRA-coding mode will now be described. In INTRA-coding mode, the control manager **160** operates the switch **102** to accept video input from input line **118**. The video signal input is received macroblock by macroblock from input **101** via the input line **118**. As they are received, the blocks of luminance and chrominance values which make up the macroblock are passed to the DCT transformation block **104**, which performs a 2-dimensional discrete cosine transform on each block of values, producing a 2-dimensional array of DCT coefficients for each block. DCT transformation block **104** produces an array of coefficient

values for each block, the number of coefficient values corresponding to the dimensions of the blocks which make up the macroblock (in this case 8x8). The DCT coefficients for each block are passed to the quantizer **106**, where they are quantized using a quantization parameter QP. Selection of the quantization parameter QP is controlled by the control manager **160** via control line **115**.

The array of quantized DCT coefficients for each block is then passed from the quantizer **106** to the video multiplex coder **170**, as indicated by line **125** in FIG. 1. The video multiplex coder **170** orders the quantized transform coefficients for each block using a zigzag scanning procedure, thereby converting the two-dimensional array of quantized transform coefficients into a one-dimensional array. Each non-zero valued quantized coefficient in the one dimensional array is then represented as a pair of values, referred to as level and run, where level is the value of the quantized coefficient and run is the number of consecutive zero-valued coefficients preceding the coefficient in question. The run and level values are further compressed in the video multiplex coder **170** using entropy coding, for example, variable length coding (VLC), or arithmetic coding.

Once the run and level values have been entropy coded using an appropriate method, the video multiplex coder **170** further combines them with control information, also entropy coded using a method appropriate for the kind of information in question, to form a single compressed bit-stream of coded image information **135**. It should be noted that while entropy coding has been described in connection with operations performed by the video multiplex coder **170**, in alternative implementations a separate entropy coding unit may be provided.

A locally decoded version of the macroblock is also formed in the encoder **100**. This is done by passing the quantized transform coefficients for each block, output by quantizer **106**, through inverse quantizer **108** and applying an inverse DCT transform in inverse transformation block **110**. In this way a reconstructed array of pixel values is constructed for each block of the macroblock. The resulting decoded image data is input to combiner **112**. In INTRA-coding mode, switch **114** is set so that the input to the combiner **112** via switch **114** is zero. In this way, the operation performed by combiner **112** is equivalent to passing the decoded image data unaltered.

As subsequent macroblocks of the current frame are received and undergo the previously described encoding and local decoding steps in blocks **104**, **106**, **108**, **110** and **112**, a decoded version of the INTRA-coded frame is built up in frame store **120**. When the last macroblock of the current frame has been INTRA-coded and subsequently decoded, the frame store **120** contains a completely decoded frame, available for use as a motion prediction reference frame in coding a subsequently received video frame in INTER-coded format.

Operation of the encoder **100** in INTER-coding mode will now be described. In INTER-coding mode, the control manager **160** operates switch **102** to receive its input from line **117**, which comprises the output of combiner **116**. The combiner **116** receives the video input signal macroblock by macroblock from input **101**. As combiner **116** receives the blocks of luminance and chrominance values which make up the macroblock, it forms corresponding blocks of prediction error information. The prediction error information represents the difference between the block in question and its prediction, produced in motion compensated prediction block **150**. More specifically, the prediction error information for each block of the macroblock comprises a two-dimensional array of values, each of which represents the difference

between a pixel value in the block of luminance or chrominance information being coded and a decoded pixel value obtained by forming a motion-compensated prediction for the block, according to the procedure to be described below. Thus, in the exemplary video coding system considered here where each macroblock comprises, for example, an assembly of 8x8 blocks comprising luminance and chrominance values, the prediction error information for each block of the macroblock similarly comprises an 8x8 array of prediction error values.

The prediction error information for each block of the macroblock is passed to DCT transformation block **104**, which performs a two-dimensional discrete cosine transform on each block of prediction error values to produce a two-dimensional array of DCT transform coefficients for each block. DCT transformation block **104** produces an array of coefficient values for each prediction error block, the number of coefficient values corresponding to the dimensions of the blocks which make up the macroblock (in this case 8x8). The transform coefficients derived from each prediction error block are passed to quantizer **106** where they are quantized using a quantization parameter QP, in a manner analogous to that described above in connection with operation of the encoder in INTRA-coding mode. As before, selection of the quantization parameter QP is controlled by the control manager **160** via control line **115**.

The quantized DCT coefficients representing the prediction error information for each block of the macroblock are passed from quantizer **106** to video multiplex coder **170**, as indicated by line **125** in FIG. 1. As in INTRA-coding mode, the video multiplex coder **170** orders the transform coefficients for each prediction error block using a certain zigzag scanning procedure and then represents each non-zero valued quantized coefficient as a run-level pair. It further compresses the run-level pairs using entropy coding, in a manner analogous to that described above in connection with INTRA-coding mode. Video multiplex coder **170** also receives motion vector information (described in the following) from motion field coding block **140** via line **126** and control information from control manager **160**. It entropy codes the motion vector information and control information and forms a single bit-stream of coded image information, **135** comprising the entropy coded motion vector, prediction error and control information.

The quantized DCT coefficients representing the prediction error information for each block of the macroblock are also passed from quantizer **106** to inverse quantizer **108**. Here they are inverse quantized and the resulting blocks of inverse quantized DCT coefficients are applied to inverse DCT transform block **110**, where they undergo inverse DCT transformation to produce locally decoded blocks of prediction error values. The locally decoded blocks of prediction error values are then input to combiner **112**. In INTER-coding mode, switch **114** is set so that the combiner **112** also receives predicted pixel values for each block of the macroblock, generated by motion-compensated prediction block **150**. The combiner **112** combines each of the locally decoded blocks of prediction error values with a corresponding block of predicted pixel values to produce reconstructed image blocks and stores them in frame store **120**.

As subsequent macroblocks of the video signal are received from the video source and undergo the previously described encoding and decoding steps in blocks **104**, **106**, **108**, **110**, **112**, a decoded version of the frame is built up in frame store **120**. When the last macroblock of the frame has been processed, the frame store **120** contains a completely decoded frame, available for use as a motion prediction ref-

reference frame in encoding a subsequently received video frame in INTER-coded format.

The details of the motion-compensated prediction performed by video encoder **100** will now be considered.

Any frame encoded in INTER-coded format requires a reference frame for motion-compensated prediction. This means, necessarily, that when encoding a video sequence, the first frame to be encoded, whether it is the first frame in the sequence, or some other frame, must be encoded in INTRA-coded format. This, in turn, means that when the video encoder **100** is switched into INTER-coding mode by control manager **160**, a complete reference frame, formed by locally decoding a previously encoded frame, is already available in the frame store **120** of the encoder. In general, the reference frame is formed by locally decoding either an INTRA-coded frame or an INTER-coded frame.

In the following description it will be assumed that the encoder performs motion compensated prediction on a macroblock basis, i.e. a macroblock is the smallest element of a video frame that can be associated with motion information. It will further be assumed that a prediction for a given macroblock is formed by identifying a region of 16×16 values in the luminance component of the reference frame that shows best correspondence with the 16×16 luminance values of the macroblock in question. Motion-compensated prediction in a video coding system where motion information may be associated with elements smaller than a macroblock will be considered later in the text.

The first step in forming a prediction for a macroblock of the current frame is performed by motion estimation block **130**. The motion estimation block **130** receives the blocks of luminance and chrominance values which make up the current macroblock of the frame to be coded via line **128**. It then performs a block matching operation in order to identify a region in the reference frame that corresponds best with the current macroblock. In order to perform the block matching operation, motion estimation block **130** accesses reference frame data stored in frame store **120** via line **127**. More specifically, motion estimation block **130** performs block-matching by calculating difference values (e.g. sums of absolute differences) representing the difference in pixel values between the macroblock under examination and candidate best-matching regions of pixels from a reference frame stored in the frame store **120**. A difference value is produced for candidate regions at all possible offsets within a predefined search region of the reference frame and motion estimation block **130** determines the smallest calculated difference value. The candidate region that yields the smallest difference value is selected as the best-matching region. The offset between the current macroblock and the best-matching region identified in the reference frame defines a "motion vector" for the macroblock in question. The motion vector typically comprises a pair of numbers, one describing the horizontal (Δx) between the current macroblock and the best-matching region of the reference frame, the other representing the vertical displacement (Δy).

Once the motion estimation block **130** has produced a motion vector for the macroblock, it outputs the motion vector to the motion field coding block **140**. The motion field coding block **140** approximates the motion vector received from motion estimation block **130** using a motion model comprising a set of basis functions and motion coefficients. More specifically, the motion field coding block **140** represents the motion vector as a set of motion coefficient values which, when multiplied by the basis functions, form an approximation of the motion vector. Typically, a translational

motion model having only two motion coefficients and basis functions is used, but motion models of greater complexity may also be used.

The motion coefficients are passed from motion field coding block **140** to motion compensated prediction block **150**. Motion compensated prediction block **150** also receives the best-matching region of pixel values identified by motion estimation block **130** from frame store **120**. Using the approximate representation of the motion vector generated by motion field coding block **140** and the pixel values of the best-matching region of pixels from the reference frame, motion compensated prediction block **150** generates an array of predicted pixel values for each block of the current macroblock. Each block of predicted pixel values is passed to combiner **116** where the predicted pixel values are subtracted from the actual (input) pixel values in the corresponding block of the current macroblock. In this way a set of prediction error blocks for the macroblock is obtained.

Operation of the video decoder **200**, shown in FIG. **2** will now be described. The decoder **200** comprises a video multiplex decoder **270**, which receives an encoded video bit-stream **135** from the encoder **100** and demultiplexes it into its constituent parts, an inverse quantizer **210**, an inverse DCT transformer **220**, a motion compensated prediction block **240**, a frame store **250**, a combiner **230**, a control manager **260**, and an output **280**.

The control manager **260** controls the operation of the decoder **200** in response to whether an INTRA- or an INTER-coded frame is being decoded. An INTRA/INTER trigger control signal, which causes the decoder to switch between decoding modes is derived, for example, from picture type information associated with each compressed video frame received from the encoder. The INTRA/INTER trigger control signal is extracted from the encoded video bit-stream by the video multiplex decoder **270** and is passed to control manager **260** via control line **215**.

Decoding of an INTRA-coded frame is performed on a macroblock-by-macroblock basis, each macroblock being decoded substantially as soon as encoded information relating to it is received in the video bit-stream **135**. The video multiplex decoder **270** separates the encoded information for the blocks of the macroblock from possible control information relating to the macroblock in question. The encoded information for each block of an INTRA-coded macroblock comprises variable length codewords representing the entropy coded level and run values for the non-zero quantized DCT coefficients of the block. The video multiplex decoder **270** decodes the variable length codewords using a variable length decoding method corresponding to the encoding method used in the encoder **100** and thereby recovers the level and run values. It then reconstructs the array of quantized transform coefficient values for each block of the macroblock and passes them to inverse quantizer **210**. Any control information relating to the macroblock is also decoded in the video multiplex decoder **270** using an appropriate decoding method and is passed to control manager **260**. In particular, information relating to the level of quantization applied to the transform coefficients is extracted from the encoded bit-stream by video multiplex decoder **270** and provided to control manager **260** via control line **217**. The control manager, in turn, conveys this information to inverse quantizer **210** via control line **218**. Inverse quantizer **210** inverse quantizes the quantized DCT coefficients for each block of the macroblock according to the control information and provides the now inverse quantized DCT coefficients to inverse DCT transformer **220**.

Inverse DCT transformer **220** performs an inverse DCT transform on the inverse quantized DCT coefficients for each

block of the macroblock to form a decoded block of image information comprising reconstructed pixel values. The reconstructed pixel values for each block of the macroblock are passed via combiner 230 to the video output 280 of the decoder where, for example, they can be provided to a display device (not shown). The reconstructed pixel values for each block are also stored in frame store 250. Because motion-compensated prediction is not used in the encoding/decoding of INTRA coded macroblocks control manager 260 controls combiner 230 to pass each block of pixel values as such to the video output 280 and frame store 250. As subsequent macroblocks of the INTRA-coded frame are decoded and stored, a decoded frame is progressively assembled in the frame store 250 and thus becomes available for use as a reference frame for motion compensated prediction in connection with the decoding of subsequently received INTER-coded frames.

INTER-coded frames are also decoded macroblock by macroblock, each INTER-coded macroblock being decoded substantially as soon as encoded information relating to it is received in the bit-stream 135. The video multiplex decoder 270 separates the encoded prediction error information for each block of an INTER-coded macroblock from encoded motion vector information and possible control information relating to the macroblock in question. As explained in the foregoing, the encoded prediction error information for each block of the macroblock comprises variable length code-words representing the entropy coded level and run values for the non-zero quantized transform coefficients of the prediction error block in question. The video multiplex decoder 270 decodes the variable length codewords using a variable length decoding method corresponding to the encoding method used in the encoder 100 and thereby recovers the level and run values. It then reconstructs an array of quantized transform coefficient values for each prediction error block and passes them to inverse quantizer 210. Control information relating to the INTER-coded macroblock is also decoded in the video multiplex decoder 270 using an appropriate decoding method and is passed to control manager 260. Information relating to the level of quantization applied to the transform coefficients of the prediction error blocks is extracted from the encoded bit-stream and provided to control manager 260 via control line 217. The control manager, in turn, conveys this information to inverse quantizer 210 via control line 218. Inverse quantizer 210 inverse quantizes the quantized DCT coefficients representing the prediction error information for each block of the macroblock according to the control information and provides the now inverse quantized DCT coefficients to inverse DCT transformer 220. The inverse quantized DCT coefficients representing the prediction error information for each block are then inverse transformed in the inverse DCT transformer 220 to yield an array of reconstructed prediction error values for each block of the macroblock.

The encoded motion vector information associated with the macroblock is extracted from the encoded video bit-stream 135 by video multiplex decoder 270 and is decoded. The decoded motion vector information thus obtained is passed via control line 225 to motion compensated prediction block 240, which reconstructs a motion vector for the macroblock using the same motion model as that used to encode the INTER-coded macroblock in encoder 100. The reconstructed motion vector approximates the motion vector originally determined by motion estimation block 130 of the encoder. The motion compensated prediction block 240 of the decoder uses the reconstructed motion vector to identify the location of a region of reconstructed pixels in a prediction reference frame stored in frame store 250. The reference frame may be, for example, a previously decoded INTRA-

coded frame, or a previously decoded INTER-coded frame. In either case, the region of pixels indicated by the reconstructed motion vector is used to form a prediction for the macroblock in question. More specifically, the motion compensated prediction block 240 forms an array of pixel values for each block of the macroblock by copying corresponding pixel values from the region of pixels identified by the motion vector. The prediction, that is the blocks of pixel values derived from the reference frame, are passed from motion compensated prediction block 240 to combiner 230 where they are combined with the decoded prediction error information. In practice, the pixel values of each predicted block are added to corresponding reconstructed prediction error values output by inverse DCT transformer 220. In this way an array of reconstructed pixel values for each block of the macroblock is obtained. The reconstructed pixel values are passed to the video output 280 of the decoder and are also stored in frame store 250. As subsequent macroblocks of the INTER-coded frame are decoded and stored, a decoded frame is progressively assembled in the frame store 250 and thus becomes available for use as a reference frame for motion-compensated prediction of other INTER-coded frames.

As explained above, in a typical video coding system, motion compensated prediction is performed on a macroblock basis, such that a macroblock is the smallest element of a video frame that can be associated with motion information. However, the video coding recommendation currently being developed by the Joint Video Team (JVT) of ISO/IEC MPEG (Motion Pictures Expert Group) and ITU-T VCEG (Video Coding Experts Group), allows motion information to be associated with elements smaller than a macroblock. In the following description, and throughout the remainder of the text, reference will be made to the version of this video coding standard described in the document by T. Weigand: "Joint Model Number 1", Doc. JVT-A003, Joint Video Team of ISO/IEC MPEG and ITU-T VCEG, January 2002, said document being included herein in its entirety. For simplicity, this version of the recommendation will be referred to as "JM1 of the JVT codec".

According to JM1 of the JVT codec, video pictures are divided into macroblocks of 16x16 pixels and are coded on a macroblock-by-macroblock basis. The coding performed follows the basic principles described above in connection with the generic video encoder and decoder of FIGS. 1 and 2. However, according to JM1, motion compensated prediction of INTER coded macroblocks is performed in manner that differs from that previously described. More specifically, each of the macroblocks is assigned a "coding mode" depending on the characteristics of the macroblock and the motion in the video sequence. Seven of the coding modes are based on dividing a macroblock to be INTER coded into a number of sub-blocks, each comprising NxM pixels, and associating motion information with each of the NxM sub-blocks, not just with the macroblock as a whole. Each of the possible schemes for dividing a macroblock into NxM sub-blocks, provided by JM1 of the JVT video codec, is illustrated in FIG. 4 of the accompanying drawings. As can be seen from the figure, the possible divisions are: 16x16, 8x16, 16x8, 8x8, 4x8, 8x4 and 4x4. Thus, if the coding mode assigned to a particular macroblock is, for example, the 16x8 mode, the macroblock is divided into two sub-blocks of size 16x8 pixels each and both sub-blocks is provided with its own motion information. In addition, an eighth coding mode, known as SKIP (or skip) mode, is provided. If this mode is assigned to a macroblock, this indicates that the macroblock is to be copied from the reference video frame without using motion compensated prediction.

13

guide the building of new reference frames for global motion compensation. More specifically, the global motion compensation scheme employed in the H.263 video coding standard uses a resampling process to generate a warped version of the reference frame for use in motion-compensated prediction of the current picture. This warped version of the reference frame may include alterations in the shape, size, and location with respect to the current picture. The resampling process is defined in terms of a mapping between the four corners of the current picture and the corresponding four corners of the reference frame. Assuming that the luminance component of the current picture has a horizontal size H and vertical size V, the mapping is performed by defining four conceptual motion vectors v^{OO} , v^{HO} , v^{OV} , and v^{HV} , each conceptual motion vector describing how to move one of the four corners of the current picture in such a way as to map it onto the corresponding corner of the reference frame. This operation is illustrated in FIG. 5. Motion compensated prediction for a macroblock of the current picture is then performed using block-matching with respect to the warped reference frame. This complicates the block matching process, as the value of each pixel of the warped reference frame used in the block matching process must be generated by mapping pixel values in the original (non-warped) reference frame into the co-ordinates of the warped reference frame. This is done using bilinear interpolation, which is a computationally intensive operation. The reader is referred to Annex P of the H.263 video coding standard for further details of the bilinear interpolation process used to generate the pixel values of the warped reference frame.

Global motion vector coding, as described in document VCEG-O20, referred to above, is a simplified version of global motion compensation. The reference frame is used as it is, but additional information is transmitted to describe the global motion and additional macroblock modes are used to indicate when global motion vectors are used. This approach is less complex than the global motion compensation technique just described, but there is additional encoder complexity associated with it. Namely, the encoder must perform extra motion estimation operations to find the global motion parameters and it also needs to evaluate more macroblock modes to find the optimal one. Moreover, the amount of extra global motion information that needs to be transmitted becomes large for small resolution video.

In view of the preceding discussion, it should be appreciated that there exists a significant unresolved technical problem relating to the coding of a digital video sequence in the presence of global motion, such as translation, panning or zooming of the camera. In particular, each of the three previously described prior art video coding solutions has some form of technical shortcoming. JM1 of the JVT codec, for example, has no special provision for taking account of global motion in video sequences. Therefore, when such motion is present it causes the video encoder to select macroblock coding modes that explicitly model the motion. This leads to a significant degradation in coding efficiency, as the global motion component is encoded in every INTER coded macroblock (or sub-block). The technique of global motion compensation (as provided by Annex P of the H.263 video coding standard) takes global motion into account by warping reference frames used in motion compensated prediction and therefore provides improved coding efficiency compared with a system in which no special measures are taken to code global motion. However, the warping process is computationally complex and additional information must be transmitted in the encoded video bit-stream to enable correct decoding of the video sequence. Although the related technique of global

14

motion vector coding is computationally less demanding than global motion compensation, it does involve a certain increase in encoder complexity and additional information must be still transmitted in the video bit-stream to enable correct decoding of the video data.

It is therefore one purpose of the present invention to combine the simplicity of local motion compensation with the coding efficiency of global motion compensation to yield a video coding system with significantly improved compression performance and a negligible increase in complexity.

SUMMARY OF THE INVENTION

In order to overcome, or at least mitigate to a large extent the problems associated with the coding of global motion in prior art video coding systems, the present invention is based on a redefinition of the skip mode concept used in JM1 of the JVT codec. The method according to the invention not only provides an improvement in coding efficiency in the presence of global motion (i.e. motion affecting the entire area of video frame), but also enables regional motion to be represented in an efficient manner.

According to the invention, the skip mode concept is redefined in such a way that a macroblock assigned to skip mode is either associated with a zero (non-active) motion vector, in which case it is treated in the same way as a conventional skip mode macroblock and copied directly from the reference frame, or it is associated with a non-zero (active) motion vector. The decision as to whether a macroblock should be associated with a zero or non-zero motion vector is made by analysing the motion of other macroblocks or sub-blocks in a region surrounding the macroblock to be coded. If it is found that the surrounding region exhibits a certain type of motion, a non-zero motion vector representative of that motion is generated and associated with the current macroblock. In particular, the continuity, velocity or deviation of motion in the surrounding macroblocks or sub-blocks can be analyzed. For example, if the motion in the surrounding region exhibits a certain level of continuity, a certain common velocity, or a particular form of divergence, a motion vector representative of that motion can be assigned to the current macroblock to be coded. On the other hand, if the region surrounding the current macroblock does not exhibit such continuity, common velocity or divergence and has an insignificant level of motion, the macroblock to be coded is assigned a zero motion vector, causing it to be copied directly from the reference frame, just as if it were a conventional SKIP mode macroblock. In this way, according to the invention, SKIP mode macroblocks can adapt to the motion in the region surrounding them, enabling global or regional motion to be taken account of in an efficient manner.

In an advantageous embodiment of the invention, the surrounding macroblocks or sub-blocks whose motion is analysed are previously encoded macroblocks neighboring the macroblock to be coded. This ensures that motion information relating to the region the surrounding a macroblock is available in the encoder (decoder) when a current macroblock is being encoded (decoded) and can be used directly to determine the motion vector to be assigned to the current macroblock. This approach enables the motion analysis of the surrounding region performed in the encoder to be duplicated exactly in the decoder. This, in turn, means that according to the invention, no additional information must be sent to the decoder in order to model global or regional motion.

As will become apparent from the detailed description of the invention presented below, redefinition of the skip mode concept as proposed by the present invention has significant

15

technical advantages compared with the previously described prior art video coding methods. In particular, the method according to the invention enables global and regional motion within a video sequence to be taken account of in an efficient manner without the need for complex warping of the reference frame or any other computationally demanding operations. Furthermore, in contrast to both the global motion compensation and global motion vector coding methods previously described, no additional information must be transmitted in the video bit-stream to enable correct decoding of the video data. Additionally, a minimal amount of modification is required to incorporate the method according to the invention into existing video coding systems that employ the concept of skip mode macroblocks.

These and other features, aspects, and advantages of embodiments of the present invention will become apparent with reference to the following detailed description in conjunction with the accompanying drawings. It is to be understood, however, that the drawings are designed solely for the purposes of illustration and not as a definition of the limits of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic block diagram of a generic video encoder according to prior art.

FIG. 2 is a schematic block diagram of a generic video decoder according to prior art and corresponding to the encoder shown in FIG. 1.

FIG. 3 illustrates the formation of a macroblock according to prior art.

FIG. 4 shows the 7 possible divisions of macroblocks into blocks according to JM1 of the JVT video codec.

FIG. 5 illustrates the generation of conceptual motion vectors for mapping the corners of a current picture to those of a reference picture in the global motion compensation scheme according to H.263 Annex P.

FIG. 6 is a schematic block diagram of a video encoder according to an embodiment of the invention.

FIG. 7 is a schematic block diagram of a video decoder according to an embodiment of the invention and corresponding to the encoder shown in FIG. 6.

FIG. 8 illustrates encoding and decoding blocks for skip mode macroblocks in an encoder or decoder according to an embodiment of the invention.

FIG. 9 shows an example of macroblock partitioning, motion in macroblocks surrounding a macroblock to be coded or decoded, and the generated skip mode motion vector for the macroblock (the darkened macroblock in the figure) according to an embodiment of the invention.

FIG. 10 is a schematic block diagram of a multimedia communications terminal in which the method according to the invention may be implemented.

BEST MODE FOR CARRYING OUT THE INVENTION

Exemplary embodiments of the invention will now be described in detail with particular reference to FIGS. 6 to 10.

According to the invention, skip (or SKIP) mode macroblocks in a video coding system adapt to the motion of surrounding image segments. If active motion is detected around a macroblock to be coded/decoded, motion parameters conforming to the motion are generated and the macroblock is motion compensated. In this way, no additional information needs to be transmitted from the encoder to the decoder.

16

FIG. 6 is a schematic block diagram of a video encoder 600 implemented according to an embodiment of the invention. When encoding frames of a digital video sequence, encoder 600 operates in a manner similar to that previously described in connection with the prior art video encoder of FIG. 1 to generate INTRA-coded and INTER-coded compressed video frames. The structure of the video encoder shown in FIG. 6 is substantially identical to that of the prior art video encoder shown in FIG. 1, with appropriate modifications to the motion estimation part necessary to implement the video encoding method according to the invention. All parts of the video encoder which implement functions and operate in a manner identical to the previously described prior art video encoder are identified with identical reference numbers.

As the present invention relates to the encoding of video frames in INTER-coded format and more particularly to details of the motion-compensated prediction performed as part of the INTER coding process, description of encoder 600 in INTRA-coding mode will be omitted and the following sections will concentrate on the operations performed by the encoder in INTER-coding mode.

In INTER-coding mode, the video encoder's control manager 160 operates switch 102 to receive its input from line 117, which comprises the output of combiner 116. The combiner 116 receives the video input signal macroblock by macroblock from input 101. As combiner 116 receives the blocks of luminance and chrominance values which make up the macroblock, it forms corresponding blocks of prediction error information, representing the difference between the block in question and its prediction, produced in motion compensated prediction block 650.

The prediction error information for each block of the macroblock is passed to DCT transformation block 104, which performs a two-dimensional discrete cosine transform on each block of prediction error values to produce a two-dimensional array of DCT transform coefficients for each block. These are passed to quantizer 106 where they are quantized using a quantization parameter QP. Selection of the quantization parameter QP is controlled by the control manager 160 via control line 115.

The quantized DCT coefficients representing the prediction error information for each block of the macroblock are then passed from quantizer 106 to video multiplex coder 170, via line 125. The video multiplex coder 170 orders the transform coefficients for each prediction error block using a zig-zag scanning procedure, represents each non-zero valued quantized coefficient as a run-level pair and compresses the run-level pairs using entropy coding. Video multiplex coder 170 also receives motion vector information from motion field coding block 640 via line 126 and control information from control manager 160. It entropy codes the motion vector information and control information and forms a single bit-stream of coded image information, 135 comprising the entropy coded motion vector, prediction error and control information.

The quantized DCT coefficients representing the prediction error information for each block of the macroblock are also passed from quantizer 106 to inverse quantizer 108. Here they are inverse quantized and the resulting blocks of inverse quantized DCT coefficients are applied to inverse DCT transform block 110, where they undergo inverse DCT transformation to produce locally decoded blocks of prediction error values. The locally decoded blocks of prediction error values are then input to combiner 112. In INTER-coding mode, switch 114 is set so that the combiner 112 also receives predicted pixel values for each block of the macroblock, generated by motion-compensated prediction block 650. The

combiner **112** combines each of the locally decoded blocks of prediction error values with a corresponding block of predicted pixel values to produce reconstructed image blocks and stores them in frame store **120**.

As subsequent macroblocks of the video signal are received from the video source and undergo the previously described encoding and decoding steps in blocks **104**, **106**, **108**, **110**, **112**, a decoded version of the frame is built up in frame store **120**. When the last macroblock of the frame has been processed, the frame store **120** contains a completely decoded frame, available for use as a motion prediction reference frame in encoding a subsequently received video frame in INTER-coded format.

The details of the motion-compensated prediction performed by video encoder **600** will now be described in detail.

Encoder **600** performs motion-compensated prediction in a manner similar to the previously described JVT codec. In other words, it is adapted to assign a coding mode to each INTER-coded macroblock depending on the characteristics of the macroblock and the motion in the video sequence being coded. When examining which coding mode to assign to particular macroblock, motion estimation block **630** performs a motion estimation operation for each coding mode in turn. Motion estimation block **630** receives the blocks of luminance and chrominance values which make up the macroblock to be coded for use in motion estimation via line **128** (see FIG. **6**). It then selects each of the possible coding modes one after the other, in turn, and performs motion estimation in order to identify a best match for the macroblock in the reference frame, on the basis of the selected coding mode and the pixel values of the macroblock to be coded. (The best match will comprise one or more best-matching regions of pixel values, depending on the coding mode). Each best-match is associated with an overall cost value, for example, a linear combination of the sum of absolute differences between the pixel values in the macroblock under examination and the best matching region in the reference frame, and an estimated number of bits required to code the mode and represent motion vectors. Once a best match has been obtained for each coding mode, motion estimation block **630** selects that coding mode which yields the smallest overall cost value as the coding mode for the current macroblock.

According to the invention, the coding modes used by encoder **600** correspond to those provided by JM1 of the JVT codec (shown in Table 3), with the exception that the SKIP mode is redefined to allow representation of global and regional motion. More specifically, the SKIP mode is modified in such a way that a zero (non-active) motion vector or a non-zero (active) motion vector is associated with each skip mode macroblock, depending on the characteristics of the motion in image segments surrounding the macroblock in question. In the following this type of motion vector will be referred to as a "skip mode motion vector".

When examining skip mode as part of the previously described motion estimation process performed in turn for each coding mode, the encoder first determines whether a zero or a non-zero skip mode motion vector should be used. To do this, the encoder is arranged to analyze the motion of image segments (e.g. macroblocks and/or sub-blocks) surrounding the macroblock to be coded. If it determines that the surrounding region exhibits a certain type of motion, for example it has characteristics indicative of global or regional motion, it generates a non-zero valued skip mode motion vector representative of the motion. On the other hand, if the encoder determines that the-region surrounding the current macroblock does not exhibit global or regional motion, but instead has an insignificant level of motion, it generates a zero

valued skip mode motion vector. In other words, if the encoder determines that the motion in the region surrounding the current macroblock has a global characteristic, skip mode coding is adapted to take account of this (by generating an associated non-zero valued skip mode motion vector representative of the motion). Alternatively if no such motion is present, a zero valued motion vector is generated causing the skip mode as modified by the invention to operate in a conventional manner i.e. a zero valued skip mode motion vector causes a macroblock to be copied directly from the reference frame.

Having performed motion estimation operations for each of the available coding modes, including skip mode as modified according to the invention, encoder **600** determines which coding mode yields the smallest overall cost value and selects that mode as the coding mode for the macroblock in question. An indication of the finally selected coding mode, for example a variable length codeword selected from the set of codewords presented in Table 3, is associated with the macroblock and included in the video bit-stream **635**. This enables a corresponding decoder to identify the coding mode for the macroblock and correctly reconstruct the macroblock using the correct form of motion-compensated prediction.

The analysis of motion in a region surrounding a macroblock to be coded to determine whether a zero valued or non-zero valued skip mode motion vector should be used will now be considered in further detail with reference to FIG. **8** of the accompanying drawings. FIG. **8** illustrates the functional elements of the motion estimation block **630** associated with generating skip mode motion vectors. These include motion information memory **801**, surrounding motion analysis block **802**, active motion parameter generation block **803** and zero motion parameter generation block **804**.

The decision whether to generate a zero valued skip mode motion vector or a non-zero valued skip mode motion vector is made by surrounding motion analysis block **802**. The decision is made by analysing and classifying the motion of macroblocks or sub-blocks in a predefined region surrounding the macroblock to be coded using a predetermined analysis scheme. In order to perform the analysis, surrounding motion analysis block **802** retrieves motion information relating to the macroblocks and/or sub-blocks in the surrounding region from motion information memory **801**. Depending on the specific details of the implementation, surrounding motion analysis block may be arranged to analyze the continuity, velocity or deviation of motion in the surrounding macroblocks or sub-blocks. For example, if the motion in the surrounding region exhibits a certain level of continuity, a certain common velocity (as depicted in FIG. **9**, for example), or a particular form of divergence, this may suggest that some form of global or regional motion is present. As a consequence surrounding motion analysis block concludes that "active motion" is present in the surrounding region and a non-zero valued skip mode motion vector should be used. On the other hand, if the region surrounding the current macroblock does not exhibit such continuity, common velocity or divergence and has a generally insignificant level of motion, the surrounding motion analysis block concludes that "non-active motion" is present in the surrounding region and consequently a zero valued skip mode motion vector should be used.

As shown in FIG. **8**, if the surrounding motion analysis block determines that "active motion" is present in the surrounding region, it sends an indication to that effect to active motion parameter generation block **803**, which forms a non-zero valued skip mode motion vector representative of the motion in the surrounding region. To do this active motion

parameter generation block **803** retrieves motion information relating to the surrounding macroblocks and/or sub-blocks from motion information memory **801**. Alternatively, this information may be passed to the active motion parameter generation block by surrounding motion analysis block **802**. If surrounding motion analysis block determines that “non-active motion” is present in the surrounding region, it sends a corresponding indication to zero motion parameter generation block **804**, which forms a zero valued skip mode motion vector.

In a particularly advantageous embodiment of the invention, the surrounding region of macroblocks or sub-blocks analyzed by the surrounding motion analysis block comprises previously encoded macroblocks neighboring the macroblock to be coded (FIG. 9). In this case, the analysis and classification of motion in the surrounding region performed in the encoder can be duplicated exactly in the decoder. This, in turn, means that according to the invention, no additional information must be sent to the decoder in order to model global or regional motion.

In an alternative embodiment of the invention the coding modes of already coded macroblocks are taken into account when deciding whether to use a zero valued or non-zero valued skip mode motion vector. For example, if the surrounding motion analysis block determines that there is one or more stationary neighboring macroblock, a zero valued skip mode motion vector is used.

In a first preferred embodiment of the invention surrounding motion analysis block **802** classifies the motion in the region surrounding the macroblock according to the following three step procedure. Firstly, surrounding motion analysis block retrieves motion information for the macroblocks or sub-blocks surrounding the macroblock to be coded (i.e. previously encoded macroblocks neighboring the macroblock to be coded, as shown in FIG. 9) and generates a median motion vector prediction for the macroblock. The median motion vector prediction is formed, for example, in a manner analogous to that used in motion vector prediction according to JM1 of the JVT codec (see T. Weigand: “Joint Model Number 1”, Doc. JVT-A003, Joint Video Team of ISO/IEC MPEG and ITU-T VCEG, January 2002). Next surrounding motion analysis block determines if any of the resulting motion vector components has an absolute value larger than a certain threshold value (for example half a pixel). If this condition is fulfilled, the motion is classified as “active motion”, otherwise it is classified as “non-active motion”. Finally, depending on the classification result, surrounding motion analysis block **802**, sends an indication to either the active motion parameter generation block **803** or the zero motion parameter generation block **804** to in order to generate the appropriate skip mode motion parameters.

Implementation of the surrounding motion analysis block according to the first preferred embodiment of the invention is particularly advantageous for two reasons. Firstly, in a typical video codec, such as the JVT codec, a median predictor is used to predict motion vectors of square image blocks. According to the first preferred embodiment, this same predictor is used in the surrounding motion analysis block and active motion parameter generation block to analyze motion in the region surrounding a macroblock to be coded and to generate motion parameters for SKIP mode macroblocks. In this way the invention can be implemented with minimal effect on the total implementation complexity of the video codec. Secondly, because the surrounding motion analysis block **802** classifies the motion in the surrounding region by generating and analyzing a median motion vector, active motion parameter generation block **803** can simply pass the

median motion parameters, already generated in the surrounding motion analysis block, to the motion compensation block. This also minimizes the implementation complexity, since there is no need to generate additional motion parameters.

In a second preferred embodiment of the invention the surrounding motion analysis block analyses the motion in vicinity of the macroblock to be coded and classifies it as either “active motion” or “non-active motion”. In the case of “active motion” the active motion parameter generation block is activated and in the case of “non-active motion” the zero motion parameter generation block is activated. In this embodiment the classification to the “non-active motion” category takes place if either or both of the two conditions below are true, otherwise the motion is classified as “active motion”:

Condition 1: The macroblock immediately above or the macroblock immediately to the left of the macroblock under consideration is not available (that is, is out of the picture or belongs to a different slice).

Condition 2: The macroblock or block immediately above, or the macroblock or block immediately to the left that are used in motion vector prediction for the 16×16 INTER mode has a zero motion vector and uses the latest picture as reference in motion compensation.

Operation of a video decoder **700** according to an embodiment of the invention will now be described with reference to FIG. 7. The structure of the video decoder illustrated in FIG. 7 is substantially identical to that of the prior art video decoder shown in FIG. 2, with appropriate modifications to those parts of the decoder that perform motion estimation operations. All parts of the video decoder which implement functions and operate in a manner identical to the previously described prior art video decoder are identified with identical reference numbers. It is further assumed that the video decoder of FIG. 7 corresponds to the encoder described in connection with FIG. 6 and is therefore capable of receiving and decoding the bit-stream **635** transmitted by encoder **600**. Furthermore, as the present invention affects the decoding of video frames in INTER-coded format, description of the operations performed by decoder **700** in connection with the decoding of INTRA-coded frames will be omitted.

INTER-coded frames are decoded macroblock by macroblock, each INTER-coded macroblock being decoded substantially as soon as encoded information relating to it is received in the bit-stream **635**. Depending on the coding mode, the compressed video data included in the bit-stream for an INTER-coded macroblock may comprise a combination of VLC encoded prediction error information for each block, motion vector information for the macroblock (or sub-blocks) and encoded control information including an indication of the coding mode used to encode the macroblock in question. If a macroblock is encoded in skip mode, no prediction error or motion vector information relating to the macroblock is included in the bit-stream.

Video multiplex decoder **270** receives the video bit-stream **635** and separates control information, including an indication of the coding mode of the macroblock from any encoded prediction error and/or motion vector information that may be present.

As explained earlier, prediction error information is encoded as variable length codewords representative of entropy coded level and run values. If prediction error information is provided for the current macroblock, the video multiplex decoder **270** recovers the level and run values by decoding the variable length codewords using a variable length decoding method corresponding to the encoding

21

method used in encoder **600**. It then reconstructs an array of quantized DCT transform coefficient values for each prediction error block and passes them to inverse quantizer **210** where they are inverse quantized. The inverse quantized DCT coefficients are then inverse transformed in the inverse DCT transformer **220** to yield an array of reconstructed prediction error values for each block of the macroblock.

Both the coding mode indication and encoded motion vector information (if any) associated with the macroblock are decoded in the video multiplex decoder and are passed via control line **225** to motion compensated prediction block **740**. Motion compensated prediction block **740** uses the coding mode indication and motion vector information (if any) to form a prediction for the macroblock in question. More specifically, the motion compensated prediction block **740** forms an array of pixel values for each block of the macroblock by copying corresponding pixel values from a region (or regions) of pixels in a reference frame. The prediction, that is the blocks of pixel values derived from the reference frame, are passed from motion compensated prediction block **740** to combiner **230** where they are combined with the decoded prediction error information (if any). In this way an array of reconstructed pixel values for each block of the macroblock is obtained.

The reconstructed pixel values are passed to the video output **280** of the decoder and are also stored in frame store **250**. Consequently, as subsequent macroblocks of the INTER-coded frame are decoded and stored, a decoded frame is progressively assembled in the frame store **250** and thus becomes available for use as a reference frame for motion-compensated prediction of other INTER-coded frames.

According to the invention, the motion compensated prediction block **740** of decoder **700** comprises a motion information memory block **801**, a surrounding motion analysis block **802**, an active motion parameter generation block **803** and a zero motion parameter generation block **804** analogous to those provided in encoder **600**. These functional blocks are used to determine whether a macroblock encoded in skip mode should be associated with a zero valued or a non-zero valued skip mode motion vector. More specifically, when it is determined that a macroblock to be decoded was encoded in skip mode, surrounding motion analysis block **802** analyses and classifies the motion of previously decoded macroblocks and/or sub-blocks in a predefined region surrounding the macroblock to be decoded in a manner exactly corresponding to that used in encoder **600**. As a result of the analysis, the macroblock in question is either associated with a non-zero valued skip mode motion vector or a zero valued skip mode motion vector. This motion vector is then used to form a prediction for the macroblock. If the macroblock is associated with a zero valued skip mode motion vector, it is reconstructed by simply copying pixel values from a corresponding location in the reference frame. If, on the other hand, it is associated with a non-zero valued motion vector, a region of pixel values indicated by the non-zero motion vector is used to generate the pixel values for the macroblock.

It should be appreciated that by modifying the skip mode concept in the manner proposed by the invention and performing surrounding motion analysis in the decoder, it is possible to take account of global or region motion in a video sequence without requiring explicit information about such motion to be provided in video bit-stream.

A terminal device comprising video encoding and decoding equipment which may be adapted to operate in accordance with the present invention will now be described. FIG. **10** of the accompanying drawings illustrates a multimedia terminal **80** implemented according to ITU-T recommenda-

22

tion H.324. The terminal can be regarded as a multimedia transceiver device. It includes elements that capture, encode and multiplex multimedia data streams for transmission via a communications network, as well as elements that receive, de-multiplex, decode and display received multimedia content. ITU-T recommendation H.324 defines the overall operation of the terminal and refers to other recommendations that govern the operation of its various constituent parts. This kind of multimedia terminal can be used in real-time applications such as conversational videotelephony, or non real-time applications such as the retrieval and/or streaming of video clips, for example from a multimedia content server in the Internet.

In the context of the present invention, it should be appreciated that the H.324 terminal shown in FIG. **10** is only one of a number of alternative multimedia terminal implementations suited to application of the inventive method. It should also be noted that a number of alternatives exist relating to the location and implementation of the terminal equipment. As illustrated in FIG. **10**, the multimedia terminal may be located in communications equipment connected to a fixed line telephone network such as an analogue PSTN (Public Switched Telephone Network). In this case the multimedia terminal is equipped with a modem **91**, compliant with ITU-T recommendations V.8, V.34 and optionally V.8bis. Alternatively, the multimedia terminal may be connected to an external modem. The modem enables conversion of the multiplexed digital data and control signals produced by the multimedia terminal into an analogue form suitable for transmission over the PSTN. It further enables the multimedia terminal to receive data and control signals in analogue form from the PSTN and to convert them into a digital data stream that can be demultiplexed and processed in an appropriate manner by the terminal.

An H.324 multimedia terminal may also be implemented in such a way that it can be connected directly to a digital fixed line network, such as an ISDN (Integrated Services Digital Network). In this case the modem **91** is replaced with an ISDN user-network interface. In FIG. **10**, this ISDN user-network interface is represented by alternative block **92**.

H.324 multimedia terminals may also be adapted for use in mobile communication applications. If used with a wireless communication link, the modem **91** can be replaced with any appropriate wireless interface, as represented by alternative block **93** in FIG. **10**. For example, an H.324/M multimedia terminal can include a radio transceiver enabling connection to the current 2nd generation GSM mobile telephone network, or the proposed 3rd generation UMTS (Universal Mobile Telephone System).

It should be noted that in multimedia terminals designed for two-way communication, that is for transmission and reception of video data, it is advantageous to provide both a video encoder and video decoder implemented according to the present invention. Such an encoder and decoder pair is often implemented as a single combined functional unit, referred to as a "codec".

A typical H.324 multimedia terminal will now be described in further detail with reference to FIG. **10**.

The multimedia terminal **80** includes a variety of elements referred to as "terminal equipment". This includes video, audio and telematic devices, denoted generically by reference numbers **81**, **82** and **83**, respectively. The video equipment **81** may include, for example, a video camera for capturing video images, a monitor for displaying received video content and optional video processing equipment. The audio equipment **82** typically includes a microphone, for example for capturing spoken messages, and a loudspeaker for reproducing received

audio content. The audio equipment may also include additional audio processing units. The telematic equipment **83**, may include a data terminal, keyboard, electronic whiteboard or a still image transceiver, such as a fax unit.

The video equipment **81** is coupled to a video codec **85**. The video codec **85** comprises a video encoder and a corresponding video decoder, both implemented according to the invention. Such an encoder and a decoder will be described in the following. The video codec **85** is responsible for encoding captured video data in an appropriate form for further transmission over a communications link and decoding compressed video content received from the communications network. In the example illustrated in FIG. **10**, the video codec is implemented according to JM1 of the JVT codec, with appropriate modifications to implement the modified SKIP mode concept according to the invention in both the encoder and the decoder of the video codec.

The terminal's audio equipment is coupled to an audio codec, denoted in FIG. **10** by reference number **86**. Like the video codec, the audio codec comprises an encoder/decoder pair. It converts audio data captured by the terminal's audio equipment into a form suitable for transmission over the communications link and transforms encoded audio data received from the network back into a form suitable for reproduction, for example on the terminal's loudspeaker. The output of the audio codec is passed to a delay block **87**. This compensates for the delays introduced by the video coding process and thus ensures synchronisation of audio and video content.

The system control block **84** of the multimedia terminal controls end-to-network signalling using an appropriate control protocol (signalling block **88**) to establish a common mode of operation between a transmitting and a receiving terminal. The signalling block **88** exchanges information about the encoding and decoding capabilities of the transmitting and receiving terminals and can be used to enable the various coding modes of the video encoder. The system control block **84** also controls the use of data encryption. Information regarding the type of encryption to be used in data transmission is passed from encryption block **89** to the multiplexer/demultiplexer (MUX/DMUX unit) **90**.

During data transmission from the multimedia terminal, the MUX/DMUX unit **90** combines encoded and synchronised video and audio streams with data input from the telematic equipment **83** and possible control data, to form a single bit-stream. Information concerning the type of data encryption (if any) to be applied to the bit-stream, provided by encryption block **89**, is used to select an encryption mode. Correspondingly, when a multiplexed and possibly encrypted multimedia bit-stream is being received, MUX/DMUX unit **90** is responsible for decrypting the bit-stream, dividing it into its constituent multimedia components and passing those components to the appropriate codec(s) and/or terminal equipment for decoding and reproduction.

If the multimedia terminal **80** is a mobile terminal, that is, if it is equipped with a radio transceiver **93**, it will be understood by those skilled in the art that it may also comprise additional elements. In one embodiment it comprises a user interface having a display and a keyboard, which enables operation of the multimedia terminal **80** by a user, a central processing unit, such as a microprocessor, which controls the blocks responsible for different functions of the multimedia terminal, a random access memory RAM, a read only memory ROM, and a digital camera. The microprocessor's operating instructions, that is program code corresponding to the basic functions of the multimedia terminal **80**, is stored in the read-only memory ROM and can be executed as required

by the microprocessor, for example under control of the user. In accordance with the program code, the microprocessor uses the radio transceiver **93** to form a connection with a mobile communication network, enabling the multimedia terminal **80** to transmit information to and receive information from the mobile communication network over a radio path.

The microprocessor monitors the state of the user interface and controls the digital camera. In response to a user command, the microprocessor instructs the camera to record digital images into the RAM. Once an image or digital video sequence is captured, or alternatively during the capturing process, the microprocessor segments the image into image segments (for example macroblocks) and uses the encoder to perform motion compensated encoding of the segments in order to generate a compressed image sequence, as explained in the foregoing description. A user may command the multimedia terminal **80** to display the captured images on its display or to send the compressed video sequence using the radio transceiver **93** to another multimedia terminal, a video telephone connected to a fixed line network (PSTN) or some other telecommunications device. In a preferred embodiment, transmission of image data is started as soon as the first segment is encoded so that the recipient can start a corresponding decoding process with a minimum delay.

Although described in the context of particular embodiments, it will be apparent to those skilled in the art that a number of modifications and various changes to these teachings may occur. Thus, while the invention has been particularly shown and described with respect to one or more preferred embodiments thereof, it will be understood by those skilled in the art that certain modifications or changes may be made therein without departing from the scope and spirit of the invention as set forth above.

In particular, according to an alternative embodiment of the invention, surrounding motion analysis block **802** is adapted to classify the motion of a surrounding region into more than two motion classes. For example, one meaningful classification involving three classes of motion would be "continuous motion", "active motion" and "non-active motion". In this way special motion parameters for the typical case of continuous motion can be generated.

In another alternative embodiment of the invention, the surrounding motion analysis block is removed and active motion parameter generation block is activated for all the skip mode macroblocks.

According to a further alternative embodiment Instead of using the surrounding motion analysis block to indicate the classification information, the indication is provided by other means (for example as side information in macroblock, slice, picture or sequence levels).

In yet another alternative embodiment, the surrounding motion analysis block may be temporarily disabled or enabled with such means.

In another alternative implementation, the macroblock mode table is rehashed depending on the output of the surrounding motion analysis block to give higher priority to more likely modes. In a related embodiment, the macroblock mode table is completely regenerated depending on the output of the surrounding motion analysis block, for example, by removing the skip.

It should also be appreciated that active motion parameters generation block **803** can be implemented in various ways. In particular embodiments of the invention it is adapted to generate the motion parameters, for example, based on the continuance, velocity or deviation of the surrounding motion. Additional side information can also be sent to guide the generation of motion parameters. In an alternative embodi-

25

ment the active motion parameter generation block is adapted to output multiple motion vectors to be used in different parts of the macroblock.

The invention can also be used to generate motion compensated prediction for other Macroblock modes in addition to or instead of the SKIP mode. It is also not limited by the macroblock structure but can be used in any segmentation based video coding system.

What is claimed is:

1. A method of encoding a video sequence, the method comprising:

assigning a skip coding mode to a first segment of a first frame of the sequence;

assigning either a zero motion vector or a predicted non-zero motion vector for the skip coding mode for the first segment based at least in part on the motion information of a second segment neighboring the first segment; and forming a prediction for the first segment with respect to a reference frame based at least in part on the assigned motion vector for the skip coding mode, wherein the assigned motion vector is one of the zero motion vector and the predicted non-zero motion vector; and

providing in an encoded bitstream an indication of the skip coding mode, wherein no further motion vector information for the first segment is coded in the encoded bitstream.

2. A method according to claim 1, wherein the second segment is a previously encoded segment neighboring the first segment.

3. A method according to claim 1, wherein if the motion in the second segment has an insignificant level of motion, the zero motion vector is assigned to the skip coding mode for the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

4. A method according to claim 1, wherein if the motion in the second segment has a motion characteristic of a global or a regional motion,

the method further comprising:

deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector.

5. A method according to claim 1, further comprising:

performing an analysis of motion of a region surrounding the first segment;

if it is determined that the region surrounding the first segment has at least one of the following types of motion: continuous motion, motion having a common velocity, and motion having a certain deviation,

the method further comprising deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector; and

otherwise, the zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for

26

the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

6. A method according to claim 1, wherein if the second segment has zero motion vector, the zero motion vector is assigned for skip coding mode of the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

7. A method of decoding an encoded video sequence, the method comprising:

receiving an indication of a skip coding mode for a first segment;

assigning either a zero motion vector or a predicted non-zero motion vector for the skip coding mode for the first segment based at least in part on the motion information of a second segment neighboring the first segment; and forming a prediction for the first segment with respect to a reference frame based at least in part on the assigned motion vector for the skip coding mode, wherein the assigned motion vector is one of the zero motion vector and the predicted non-zero motion vector.

8. A method according to claim 7, further comprising:

performing an analysis of motion of a region surrounding the first segment;

if it is determined that the region surrounding the first segment has at least one of the following types of motion: continuous motion, motion having a common velocity, and motion having a certain deviation,

the method further comprising deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned for the skip coding mode of the first segment; and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector; and

otherwise, the zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

9. A method according to claim 7, wherein if a segment in a previously decoded region surrounding the first segment has zero motion vector, the zero-motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

10. A video encoder for encoding a video sequence, the encoder comprises:

a coding controller for assigning a skip coding mode to a first segment;

a motion estimation block for

assigning either a zero motion vector or a predicted non-zero motion vector for the skip coding mode for the first segment based at least in part on the motion information of a second segment neighboring the first segment; and

forming a prediction for the first segment with respect to a reference frame based at least in part on the assigned motion vector for the skip coding mode, wherein the assigned motion vector is one of the zero motion vector and the predicted non-zero motion vector; and

27

a multiplexer for providing in an encoded bitstream an indication of the skip coding mode, wherein no further motion vector information for the first segment is coded in the encoded bitstream.

11. An encoder according to claim 10, wherein the second segment is a previously encoded segment neighboring the first segment.

12. An encoder according to claim 10, wherein if the second segment has an insignificant level of motion, the motion estimation block is arranged to assign the zero motion vector for the skip coding mode of the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

13. An encoder according to claim 10, wherein if the second segment has a motion characteristic of a global or a regional motion,

the motion estimation block is arranged to derive the predicted non-zero motion vector based at least in part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector.

14. An encoder according to claim 10, wherein the motion estimation block is arranged to perform an analysis of motion of a region surrounding the first segment;

if it is determined that the region surrounding the first segment has at least one of the following types of motion: continuous motion, motion having a common velocity, and motion having a certain deviation

the motion estimation block is further arranged to derive a predicted non-zero motion vector based at least in part on the motion vector of the second segment; and the predicted non-zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector; and

otherwise, the zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

15. An encoder according to claim 10, wherein if a segment in a region surrounding the first segment has zero motion vector, the encoder is arranged to assign the zero motion vector for the skip coding mode of the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

16. A video decoder for decoding an encoded video sequence, the decoder comprising:

a demultiplexer for receiving an indication of a skip coding mode assigned to a first segment;

a motion compensated prediction block for

assigning either a zero motion vector or a predicted non-zero motion vector for the skip coding mode for the first segment based at least in part on the motion information of a second segment neighboring the first segment; and

forming a prediction for the first segment with respect to a reference frame based at least in part on the assigned motion vector for the skip coding mode, wherein the

28

assigned motion vector is one of the zero motion vector and the predicted non-zero motion vector.

17. A decoder according to claim 16, wherein if the second segment has an insignificant level of motion, the decoder is arranged to assign the zero-motion vector to the skip coding mode for the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

18. A decoder according to claim 16, wherein if the second segment has a motion characteristic of a global or a regional motion, the decoder is arranged to derive the predicted non-zero motion vector based at least in part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector.

19. A decoder according to claim 16, wherein the motion compensated prediction block is configured to perform an analysis of motion of a region surrounding the first segment; and

if it is determined that the region surrounding the first segment has at least one of the following types of motion: continuous motion, motion having a common velocity, motion having a certain deviation,

the motion compensated prediction block further configured to derive a predicted non-zero motion vector based at least in part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector; and

otherwise, the zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

20. A decoder according to claim 16, wherein if a segment in a region surrounding the first segment has zero motion vector, the zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

21. A multimedia terminal, comprising an encoder according to claim 10.

22. A multimedia terminal comprising a decoder according to claim 16.

23. A method according to claim 1, wherein if the second segment has a non-zero motion vector,

the method further comprising deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned for the skip coding mode of the first segment; and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector.

24. A method according to claim 1, wherein if the second segment has a zero motion vector and the second segment is predicted using motion-compensated prediction from the reference picture, the zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the

first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

25. A method according to claim 1, wherein if the second segment has a zero motion vector and the second segment is predicted using motion-compensated prediction from a second reference picture immediately preceding the picture second segment belongs to, the zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

26. A method according to claim 1, further comprising: performing an analysis of motion information of the second segment and motion information of a third segment neighboring the first segment; and

determining whether a region surrounding the first segment has a global or a regional motion in a video sequence based at least in part on a characteristic of the motion vector of the second segment and the motion vector of the third segment.

27. A method according to claim 26, wherein if the region surrounding the first segment has a global or a regional motion in a video sequence,

the method further comprising deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment and the motion vector of the third segment; and

the predicted non-zero motion vector is assigned for the skip coding mode of the first segment; and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector.

28. A method according to claim 1, further comprising: deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment.

29. A method according to claim 1, further comprising: deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment and motion vector of a third segment neighboring the first segment.

30. A method according to claim 1, wherein no residual information is provided for the first segment in the encoded bitstream.

31. A method according to claim 1, further comprising: deriving a predicted motion vector based at least in part on the motion vector of the second segment and motion vector of a third segment neighboring the first segment; and

if any component of the predicted motion vector has an absolute value larger than a certain threshold value, the predicted motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted motion vector; and

if none of components of the predicted motion vector has an absolute value larger than the certain threshold value, the zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

32. A method according to claim 7, wherein if the second segment has a zero motion vector, the zero motion vector is assigned to the skip coding mode of the first segment and the

prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

33. A method according to claim 7, wherein if the second segment has an insignificant level of motion, the zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

34. A method according to claim 7, wherein if the second segment has a non-zero motion vector,

the method further comprising deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned for the skip coding mode of the first segment; and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector.

35. A method according to claim 7, characterized in that if the second segment has a motion characteristic of a global or a regional motion,

the method further comprising deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector.

36. A method according to claim 7, wherein if the second segment has a zero motion vector and the second segment is predicted using motion-compensated prediction from the reference picture, the zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

37. A method according to claim 7, further comprising: performing an analysis of motion information of the second segment and motion information of a third segment neighboring the first segment;

determining whether a region surrounding the first segment has a global or a regional motion in a video sequence based at least in part on a characteristic of the motion vector of the second segment and the motion vector of the third segment.

38. A method according to claim 37, wherein if the region surrounding the first segment has a global or a regional motion in a video sequence,

the method further comprising deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment and the motion vector of the third segment; and

the predicted non-zero motion vector is assigned for the skip coding mode of the first segment; and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector.

39. A method according to claim 7, further comprising: deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment.

40. A method according to claim 7, further comprising: deriving the predicted non-zero motion vector based at least in part on the motion vector of the second segment and motion vector of a third segment neighboring the first segment.

31

41. A method according to claim 7, wherein no residual information is provided for the first segment in the encoded bitstream.

42. A method according to claim 7, further comprising:
 deriving a predicted motion vector based at least in part on
 the motion vector of the second segment and motion
 vector of a third segment neighboring the first segment;
 and

if any component of the predicted motion vector has an
 absolute value larger than a certain threshold value, the
 predicted motion vector is assigned for the skip coding
 mode of the first segment, and the prediction for the first
 segment is formed by a motion compensated prediction
 with respect to the reference frame based at least in part
 on the predicted motion vector; and

if none of components of the predicted motion vector has
 an absolute value larger than the certain threshold value,
 the zero motion vector is assigned for the skip coding
 mode of the first segment, and the prediction for the first
 segment is formed with respect to a corresponding seg-
 ment of the reference frame associated with the zero
 motion vector.

43. A method according to claim 1, wherein if the second
 segment has a zero motion vector and the second segment is
 predicted using motion-compensated prediction from a sec-
 ond reference picture immediately preceding the picture sec-
 ond segment belongs to, the zero motion vector is assigned to
 the skip coding mode of the first segment and the prediction
 for the first segment is formed with respect to a corresponding
 segment of the reference frame associated with the zero
 motion vector.

44. An encoder according to claim 10, wherein if the sec-
 ond segment has a non-zero motion vector,

the motion estimation block is further arranged to derive
 the predicted non-zero motion vector based at least in
 part on the motion vector of the second segment; and

the predicted non-zero motion vector is assigned for the
 skip coding mode for the first segment; and the predic-
 tion for the first segment is formed by a motion compen-
 sated prediction with respect to the reference frame
 based at least in part on the predicted non-zero motion
 vector.

45. An encoder according to claim 10, further wherein the
 motion estimation block is further arranged to:

perform an analysis of motion information of the second
 segment and motion information of a third segment
 neighboring the first segment;

determine whether a region surrounding the first segment
 has a global or a regional motion in a video sequence
 based at least in part on a characteristic of the motion
 vector of the second segment and the motion vector of
 the third segment.

46. An encoder according to claim 45, wherein if the region
 surrounding the first segment has a global or a regional
 motion in a video sequence,

the motion estimation block further arranged to derive the
 predicted non-zero motion vector based at least in part
 on the motion vector of the second segment and the
 motion vector of the third segment; and

the predicted non-zero motion vector is assigned for the
 skip coding mode for the first segment; and the predic-
 tion for the first segment is formed by a motion compen-
 sated prediction with respect to the reference frame
 based at least in part on the predicted non-zero motion
 vector.

32

47. An encoder according to claim 10, wherein the motion
 estimation block further arranged to derive the predicted non-
 zero motion vector based at least in part on the motion vector
 of the second segment.

48. An encoder according to claim 10, wherein the motion
 estimation block further arranged to derive the predicted non-
 zero motion vector based at least in part on the motion vector
 of the second segment and motion vector of a third segment
 neighboring the first segment.

49. An encoder according to claim 10, wherein no residual
 information is provided for the first segment in the encoded
 bitstream.

50. An encoder according to claim 10, wherein the motion
 estimation block further arranged to derive a predicted
 motion vector based at least in part on the motion vector of the
 second segment and motion vector of a third segment neigh-
 boring the first segment; and

if any component of the predicted motion vector has an
 absolute value larger than a certain threshold value, the
 predicted motion vector is assigned for the skip coding
 mode of the first segment, and the prediction for the first
 segment is formed by a motion compensated prediction
 with respect to the reference frame based at least in part
 on the predicted motion vector; and

if none of components of the predicted motion vector has
 an absolute value larger than the certain threshold value,
 the zero motion vector is assigned for the skip coding
 mode of the first segment, and the prediction for the first
 segment is formed with respect to a corresponding seg-
 ment of the reference frame associated with the zero
 motion vector.

51. An encoder according to claim 10, wherein if the sec-
 ond segment has a zero motion vector, the zero motion vector
 is assigned to the skip coding mode of the first segment and
 the prediction for the first segment is formed with respect to a
 corresponding segment of the reference frame associated
 with the zero motion vector.

52. An encoder according to claim 10, wherein if the sec-
 ond segment has a zero motion vector and the second segment
 is predicted using motion-compensated prediction from the
 reference picture, the zero motion vector is assigned to the
 skip coding mode of the first segment and the prediction for
 the first segment is formed with respect to a corresponding
 segment of the reference frame associated with the zero
 motion vector.

53. An encoder according to claim 10, wherein if the sec-
 ond segment has a zero motion vector and the second segment
 is predicted using motion-compensated prediction from a
 second reference picture immediately preceding the picture
 second segment belongs to, the zero motion vector is assigned
 to the skip coding mode of the first segment and the prediction
 for the first segment is formed with respect to a corresponding
 segment of the reference frame associated with the zero
 motion vector.

54. A decoder according to claim 16, wherein if the second
 segment has a zero motion vector, the zero-motion vector is
 assigned to the skip coding mode for the first segment and the
 prediction for the first segment is formed with respect to a
 corresponding segment of the reference frame associated
 with the zero motion vector.

55. A decoder according to claim 16, wherein if the second
 segment has a non-zero motion vector,

the motion compensated prediction block further arranged
 to derive the predicted non-zero motion vector based at
 least in part on the motion vector of the second segment;
 and

33

the predicted non-zero motion vector is assigned for the skip coding mode for the first segment; and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector. 5

56. A decoder according to claim 16, wherein the motion estimation block further arranged to:

perform an analysis of motion information of the second segment and motion information of a third segment neighboring the first segment; 10

determine whether a region surrounding the first segment has a global or a regional motion in a video sequence based at least in part on a characteristic of the motion vector of the second segment and the motion vector of the third segment. 15

57. A decoder according to claim 56, wherein if the region surrounding the first segment has a global or a regional motion in a video sequence,

the motion estimation block further arranged to derive the predicted non-zero motion vector based at least in part on the motion vector of the second segment and the motion vector of the third segment; and 20

the predicted non-zero motion vector is assigned for the skip coding mode for the first segment; and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted non-zero motion vector. 25

58. A decoder according to claim 16, wherein the motion estimation block further arranged to derive the predicted non-zero motion vector based at least in part on the motion vector of the second segment. 30

59. A decoder according to claim 16, wherein the motion estimation block further arranged to derive the predicted non-zero motion vector based at least in part on the motion vector of the second segment and motion vector of a third segment neighboring the first segment. 35

60. A decoder according to claim 16, wherein no residual information is provided for the first segment in an encoded bitstream. 40

61. A decoder according to claim 16, wherein the motion estimation block further arranged to derive a predicted

34

motion vector based at least in part on the motion vector of the second segment and motion vector of a third segment neighboring the first segment; and

if any component of the predicted motion vector has an absolute value larger than a certain threshold value, the predicted motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed by a motion compensated prediction with respect to the reference frame based at least in part on the predicted motion vector; and

if none of components of the predicted motion vector has an absolute value larger than the certain threshold value, the zero motion vector is assigned for the skip coding mode of the first segment, and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

62. A decoder according to claim 16, wherein if the second segment has a zero motion vector and the second segment is predicted using motion-compensated prediction from the reference picture, the zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

63. A decoder according to claim 16, wherein if the second segment has a zero motion vector and the second segment is predicted using motion-compensated prediction from a second reference picture immediately preceding the picture second segment belongs to, the zero motion vector is assigned to the skip coding mode of the first segment and the prediction for the first segment is formed with respect to a corresponding segment of the reference frame associated with the zero motion vector.

64. A decoder according to claim 16, wherein no further motion vector information for the first segment is retrieved from an encoded bitstream.

65. A method according to claim 7, wherein no further motion vector information for the first segment is retrieved from the encoded bitstream.

(57) **ABSTRACT**

A method for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order. An indication of at least one image frame is encoded into the video sequence, which indicated image frame is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence. In the decoding phase, the indication of at least one image frame is decoded from the video sequence, and the decoding of the video sequence is started from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame.

GROUPING OF IMAGE FRAMES IN VIDEO CODING

RELATED PATENT DOCUMENTS

This application is a continuation of U.S. patent application Ser. No. 10/306,942 filed on Nov. 29, 2002 now U.S. Pat. No. 7,894,521 which is incorporated herein by reference in its entirety.

FIELD OF THE INVENTION

The invention relates to the grouping of multimedia files, particularly video files and particularly in connection with streaming.

BACKGROUND OF THE INVENTION

The term 'streaming' refers to simultaneous sending and playback of data, typically multimedia data, such as audio and video files, in which the recipient may begin data playback already before all the data to be transmitted has been received. Multimedia data streaming systems comprise a streaming server and terminal devices that the recipients use for setting up a data connection, typically via a telecommunications network, to the streaming server. From the streaming server the recipients retrieve either stored or real-time multimedia data, and the playback of the multimedia data can then begin, most advantageously almost in real-time with the transmission of the data, by means of a streaming application included in the terminal.

From the point of view of the streaming server, the streaming may be carried out either as normal streaming or as progressive downloading to the terminal. In normal streaming the transmission of the multimedia data and/or the data contents are controlled either by making sure that the bit rate of the transmission substantially corresponds to the playback rate of the terminal device, or, if the telecommunications network used in the transmission causes a bottleneck in data transfer, by making sure that the bit rate of the transmission substantially corresponds to the bandwidth available in the telecommunications network. In progressive downloading the transmission of the multimedia data and/or the data contents do not necessarily have to be interfered with at all, but the multimedia files are transmitted as such to the recipient, typically by using transfer protocol flow control. The terminals then receive, store and reproduce an exact copy of the data transmitted from the server, which copy can then be later reproduced again on the terminal without needing to start a streaming again via the telecommunications network. The multimedia files stored in the terminal are, however, typically very large and their transfer to the terminal is time-consuming, and they require a significant amount of storage memory capacity, which is why a normal streaming is often preferred.

The video files in multimedia files comprise a great number of still image frames, which are displayed rapidly in succession (of typically 15 to 30 frames per s) to create an impression of a moving image. The image frames typically comprise a number of stationary background objects, determined by image information which remains substantially unchanged, and few moving objects, determined by image information that changes to some extent. The information comprised by consecutively displayed image frames is typically largely similar, i.e. successive image frames comprise a considerable amount of redundancy. The redundancy appearing in video files can be divided into spatial, temporal and spectral redundancy. Spatial redundancy refers to the mutual correlation of

2

adjacent image pixels, temporal redundancy refers to the changes taking place in specific image objects in subsequent frames, and spectral redundancy to the correlation of different colour components within an image frame.

To reduce the amount of data in video files, the image data can be compressed into a smaller form by reducing the amount of redundant information in the image frames. In addition, while encoding, most of the currently used video encoders downgrade image quality in image frame sections that are less important in the video information. Further, many video coding methods allow redundancy in a bit stream coded from image data to be reduced by efficient, lossless coding of compression parameters known as VLC (Variable Length Coding).

In addition, many video coding methods make use of the above-described temporal redundancy of successive image frames. In that case a method known as motion-compensated temporal prediction is used, i.e. the contents of some (typically most) of the image frames in a video sequence are predicted from other frames in the sequence by tracking changes in specific objects or areas in successive image frames. A video sequence always comprises some compressed image frames the image information of which has not been determined using motion-compensated temporal prediction. Such frames are called INTRA-frames, or I-frames. Correspondingly, motion-compensated video sequence image frames predicted from previous image frames, are called INTER-frames, or P-frames (Predicted). The image information of P-frames is determined using one I-frame and possibly one or more previously coded P-frames. If a frame is lost, frames dependent on it can no longer be correctly decoded.

An I-frame typically initiates a video sequence defined as a Group of Pictures (GOP), the P-frames of which can only be determined on the basis of the I-frame and the previous P-frames of the GOP in question. The next I-frame begins a new group of pictures GOP, the image information comprised by which cannot thus be determined on the basis of the frames of the previous GOP. In other words, groups of pictures are not temporally overlapping, and each group of picture can be decoded separately. In addition, many video compression methods employ bi-directionally predicted B-frames (Bi-directional), which are set between two anchor frames (I- and P-frames, or two P-frames) within a group of pictures GOP, the image information of a B-frame being predicted from both the previous anchor frame and the one succeeding the B-frame. B-frames therefore provide image information of higher quality than P-frames, but typically they are not used as anchor frames, and therefore their removal from the video sequence does not degrade the quality of subsequent images. However, nothing prevents B-frames from being used as anchor frames as well, only in that case they cannot be removed from the video sequence without deteriorating the quality of the frames dependent on them.

Each video frame may be divided into what are known as macroblocks that comprise the colour components (such as Y, U, V) of all pixels of a rectangular image area. More specifically, a macroblock consists of at least one block per colour component, the blocks each comprising colour values (such as Y, U or V) of one colour level in the image area concerned. The spatial resolution of the blocks may differ from that of the macroblocks, for example U- and V-components may be displayed using only half of the resolution of Y-component. Macroblocks can be further grouped into slices, for example, which are groups of macroblocks that are typically selected in the scanning order of the image. Temporal prediction is typi-

3

cally carried out in video coding methods block- or macroblock-specifically, instead of image-frame-specifically.

To allow for flexible streaming of video files, many video coding systems employ scalable coding in which some elements or element groups of a video sequence can be removed without affecting the reconstruction of other parts of the video sequence. Scalability is typically implemented by grouping the image frames into a number of hierarchical layers. The image frames coded into the image frames of the base layer substantially comprise only the ones that are compulsory for the decoding of the video information at the receiving end. The base layer of each group of pictures GOP thus comprises one I-frame and a necessary number of P-frames. One or more enhancement layers can be determined below the base layer, each one of the layers improving the quality of the video coding in comparison with an upper layer. The enhancement layers thus comprise P- or B-frames predicted on the basis of motion-compensation from one or more upper layer images. The frames are typically numbered according to an arithmetical series.

In streaming, transmission bit rate must be controllable either on the basis of the bandwidth to be used or the maximum decoding or bit rate value of the recipient. Bit rate can be controlled either at the streaming server or in some element of the telecommunications network, such as an Internet router or a base station of a mobile communications network. The simplest means for the streaming server to control the bit rate is to leave out B-frames having a high information content from the transmission. Further, the streaming server may determine the number of scalability layers to be transmitted in a video stream, and thus the number of the scalability layers can be changed always when a new group of pictures GOP begins. It is also possible to use different video sequence coding methods. Correspondingly, B-frames, as well as other P-frames of the enhancement layers, can be removed from the bit stream in a telecommunications network element.

The above arrangement involves a number of drawbacks. Many coding methods, such as the coding according to the ITU-T (International Telecommunications Union, Telecommunications Standardization Sector) standard H.263, are familiar with a procedure called reference picture selection. In reference picture selection at least a part of a P-image has been predicted from at least one other image than the one immediately preceding the P-image in the time domain. The selected reference image is signalled in a coded bit stream or in bit stream header fields image-, image-segment- (such as a slice or a group of macroblocks), macroblock-, or block-specifically. The reference picture selection can be generalized such that the prediction can also be made from images temporally succeeding the image to be coded. Further, the reference picture selection can be generalized to cover all temporally predicted frame types, including B-frames. Since it is possible to also select at least one image preceding an I-image that begins a group of pictures GOP as the reference image, a group of pictures employing reference picture selection cannot necessarily be decoded independently. In addition, the adjusting of scalability or coding method in the streaming server or a network element becomes difficult, because the video sequence must be decoded, parsed and buffered for a long period of time to allow any dependencies between different image groups to be detected.

A further problem relates to detection of image frames from which a decoder can start the decoding process. The detection is useful for multiple purposes. For example, an end-user may wish to start browsing a video file from the middle of a video sequence. Another example relates to starting the reception of a broadcast or multicast video transmis-

4

sion from the middle of the video transmission. A third example relates to on-demand streaming from a server and occurs when an end-user wishes to start playback from a certain position of a stream.

BRIEF DESCRIPTION OF THE INVENTION

Now there is invented an improved method and equipment implementing the method, that enable detection of image frames from which a decoder can start the decoding process. Various aspects of the invention include methods, a video encoder, a video decoder, and computer programs that are characterized by what is stated in the independent claims. The preferred embodiments of the invention are disclosed in the dependent claims.

The invention is based on the idea of encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference picture is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order. An indication of at least one image frame is encoded into the video sequence, which indicated image frame is the first picture, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence. Respectively, in the decoding phase, the indication of at least one image frame is decoded from the video sequence, and the decoding of the video sequence is started from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame.

Consequently, the idea of the present invention is to determine an initiation picture in an independently decodable group of pictures, whereby in the decoding phase any picture prior to said initiation picture is defined as unusable for reference. Accordingly, after decoding the initiation picture, all following pictures of the independently decodable sequence can be decoded without prediction from any picture decoded prior to said initiation picture.

According to an embodiment, the indication is encoded into the video sequence as a separate flag included in the header of a slice.

According to an embodiment, identifier values for pictures are encoded according to a numbering scheme, and the identifier value for the indicated first picture of an independent sequence is reset, preferably to zero.

According to an embodiment, an identifier value for the independent sequence is encoded into the video sequence.

An advantage of the procedure of the invention is that it enables to start browsing a video sequence from a random point, i.e. it provides the decoder with the information about the first picture of an independently decodable sequence. Thus, the decoder knows that by decoding this first picture, it is possible to continue the decoding process without any prediction from any prior picture. Accordingly, a further advantage is that the decoder may discard any picture decoded prior to said initiation picture from its buffer memory, since the prior pictures are no longer needed in the decoding process. A further advantage is that the procedure of the invention allows a separate video sequence to be easily inserted into another video sequence.

A further advantage is that enables identification of a picture boundary between two back-to-back initiation pictures by looking at the sub-sequence number of the initiation pictures. A yet further advantage relates to detection of losses of image frames that start an independently decodable sub-sequence. If such an image frame is lost e.g. during transmission, it is unlikely that any error concealment method would

5

result into a subjectively satisfactory image quality. It is therefore an advantage that decoders are provided means to detect losses of image frames that start an independently decodable sub-sequence. Decoders may react to such a loss by requesting a retransmission or picture refresh, for example.

BRIEF DESCRIPTION OF THE DRAWINGS

In the following, the invention will be described in connection with the preferred embodiments and with reference to the accompanying drawings, in which

FIG. 1 illustrates a common multimedia data streaming system in which the scalable coding hierarchy of the invention can be applied;

FIG. 2 illustrates a scalable coding hierarchy of a preferred embodiment of the invention;

FIGS. 3a and 3b illustrate embodiments of the invention for adjusting scalability;

FIGS. 4a, 4b and 4c illustrate embodiments of the invention for adjusting image numbering;

FIGS. 5a, 5b and 5c illustrate embodiments of the invention for using B-frames in a scalable coding hierarchy;

FIGS. 6a, 6b and 6c illustrate scalable coding hierarchies of preferred embodiments of the invention in connection with reference picture selection; and

FIG. 7 illustrates an arrangement according to a preferred embodiment of the invention for coding scene transition.

DETAILED DESCRIPTION OF THE INVENTION

In the following, a general-purpose multimedia data streaming system is disclosed, the basic principles of which can be applied in connection with any telecommunications system. Although the invention is described here with a particular reference to a streaming system, in which the multimedia data is transmitted most preferably through a telecommunications network employing a packet-switched data protocol, such as an IP network, the invention can equally well be implemented in circuit-switched networks, such as fixed telephone networks PSTN/ISDN (Public Switched Telephone Network/integrated Services Digital Network) or in mobile communications networks PLMN (Public Land Mobile Network). Further, the invention can be applied in the streaming of multimedia files in the form of both normal streaming and progressive downloading, and for implementing video calls, for example.

It is also to be noted that although the invention is described here with a particular reference to streaming systems and the invention can also be advantageously applied in them, the invention is not restricted to streaming systems alone, but can be applied in any video reproduction system, irrespective of how a video file that is to be decoded is downloaded and where it is downloaded from. The invention can therefore be applied for example in the playback of a video file to be downloaded from a DVD disc or from some other computer memory carrier, for example in connection with varying processing capacity available for video playback. In particular, the invention can be applied to different video codings of low bit rate that are typically used in telecommunications systems subject to bandwidth restrictions. One example is the system defined in the ITU-T standard H.263 and the one that is being defined in H.26L (possibly later to become H.264). In connection with these, the invention can be applied to mobile stations, for example, in which case the video playback can be made to adjust both to changing transfer capacity or channel

6

quality and to the processor power currently available, when the mobile station is used also for executing other applications than video playback.

It is further to be noted that, for the sake of clarity, the invention will be described below by giving an account of image frame coding and temporal predicting on image frame level. However, in practice coding and temporal predicting typically take place on block or macroblock level, as described above.

With reference to FIG. 1, a typical multimedia streaming system will be described, which is a preferred system for applying the procedure of the invention.

A multimedia data streaming system typically comprises one or more multimedia sources **100**, such as a video camera and a microphone, or video image or computer graphic files stored in a memory carrier. Raw data obtained from the different multimedia sources **100** is combined into a multimedia file in an encoder **102**, which can also be referred to as an editing unit. The raw data arriving from the one or more multimedia sources **100** is first captured using capturing means **104** included in the encoder **102**, which capturing means can be typically implemented as different interface cards, driver software, or application software controlling the function of a card. For example, video data may be captured using a video capture card and the associated software. The output of the capturing means **104** is typically either an uncompressed or slightly compressed data flow, for example uncompressed video frames of the YUV 4:2:0 format or motion-JPEG image format, when a video capture card is concerned.

An editor **106** links different media flows together to synchronize video and audio flows to be reproduced simultaneously as desired. The editor **106** may also edit each media flow, such as a video flow, by halving the frame rate or by reducing spatial resolution, for example. The separate, although synchronized, media flows are compressed in a compressor **108**, where each media flow is separately compressed using a compressor suitable for the media flow. For example, video frames of the YUV 4:2:0 format may be compressed using the low bit rate video coding according to the ITU-T recommendation H.263 or H.26L. The separate, synchronized and compressed media flows are typically interleaved in a multiplexer **110**, the output obtained from the encoder **102** being a single, uniform bit flow that comprises data of a plural number of media flows and that may be referred to as a multimedia file. It is to be noted that the forming of a multimedia file does not necessarily require the multiplexing of a plural number of media flows into a single file, but the streaming server may interleave the media flows just before transmitting them.

The multimedia files are transferred to a streaming server **112**, which is thus capable of carrying out the streaming either as real-time streaming or in the form of progressive downloading. In progressive downloading the multimedia files are first stored in the memory of the server **112** from where they may be retrieved for transmission as need arises. In real-time streaming the editor **102** transmits a continuous media flow of multimedia files to the streaming server **112**, and the server **112** forwards the flow directly to a client **114**. As a further option, real-time streaming may also be carried out such that the multimedia files are stored in a storage that is accessible from the server **112**, from where real-time streaming can be driven and a continuous media flow of multimedia files is started as need arises. In such case, the editor **102** does not necessarily control the streaming by any means. The streaming server **112** carries out traffic shaping of the multimedia data as regards the bandwidth available or the maximum

decoding and playback rate of the client **114**, the streaming server being able to adjust the bit rate of the media flow for example by leaving out B-frames from the transmission or by adjusting the number of the scalability layers. Further, the streaming server **112** may modify the header fields of a multiplexed media flow to reduce their size and encapsulate the multimedia data into data packets that are suitable for transmission in the telecommunications network employed. The client **114** may typically adjust, at least to some extent, the operation of the server **112** by using a suitable control protocol. The client **114** is capable of controlling the server **112** at least in such a way that a desired multimedia file can be selected for transmission to the client, in addition to which the client is typically capable of stopping and interrupting the transmission of a multimedia file.

When the client **114** is receiving a multimedia file, the file is first supplied to a demultiplexer **116**, which separates the media flows comprised by the multimedia file. The separate, compressed media flows are then supplied to a decompressor **118** where each separate media flow is decompressed by a decompressor suitable for each particular media flow. The decompressed and reconstructed media flows are supplied to a playback unit **120** where the media flows are rendered at a correct pace according to their synchronization data and supplied to presentation means **124**. The actual presentation means **124** may comprise for example a computer or mobile station display, and loudspeaker means. The client **114** also typically comprises a control unit **122** that the end user can typically control through a user interface and that controls both the operation of the server, through the above-described control protocol, and the operation of the playback unit **120**, on the basis of the instructions given by the end user.

It is to be noted that the transfer of multimedia files from the streaming server **112** to the client **114** takes place through a telecommunications network, the transfer path typically comprising a plural number of telecommunications network elements. It is therefore possible that there is at least some network element that can carry out traffic shaping of multimedia data with regard to the available bandwidth or the maximum decoding and playback rate of the client **114** at least partly in the same way as described above in connection with the streaming server.

Scalable coding will be described below with reference to a preferred embodiment of the invention and an example illustrated in FIG. 2. FIG. 2 shows part of a compressed video sequence having a first frame **200**, which is an INTRA frame, or I-frame, and thus an independently determined video frame the image information of which is determined without using motion-compensated temporal prediction. The I-frame **200** is placed on a first scalability layer, which may be referred to as an INTRA layer. Each scalability layer is assigned a unique identifier, such as the layer number. The INTRA layer may therefore be given the number 0, for example, or some other alphanumeric identifier, for example a letter, or a combination of a letter and a number.

Correspondingly, sub-sequences consisting of groups of one or more video frames are determined for each scalability layer, at least one of the images in a group (typically the first or the last one) being temporally predicted at least from a video frame of another, sub-sequence of typically either a higher or the same scalability layer, the rest of the video frames being temporally predicted either from only the video frames of the same sub-sequence, or possibly also from one or more video frames of said second sub-sequence. A sub-sequence may be decoded independently, irrespective of other sub-sequences, except said second sub-sequence. The sub-sequences of each scalability layer are assigned a unique

identifier using for example consecutive numbering starting with number 0 given for the first sub-sequence of a scalability layer. Since the I-frame **200** is determined independently and can also be decoded independently upon reception, irrespective of other image frames, it also forms in a way a separate sub-sequence.

An essential aspect of the present invention is therefore to determine each sub-sequence in terms of those sub-sequences the sub-sequence is dependent on. In other words, a sub-sequence comprises information about all the sub-sequences that have been directly used for predicting the image frames of the sub-sequence in question. This information is signalled in a video sequence bit stream, preferably separate from the actual image information, and therefore the image data of the video sequence can be preferably adjusted because it is easy to determine video sequence portions that are to be independently decoded and can be removed without affecting the decoding of the rest of the image data.

Next, within each sub-sequence, the video frames of the sub-sequence are given image numbers, using for example consecutive numbering that starts with the number 0 given to the first video frame of the sub-sequence. Since the I-frame **200** also forms a separate sub-sequence, its image number is 0. In FIG. 2, the I-frame **200** shows the type (I), sub-sequence identifier and image number (0.0) of the frame.

FIG. 2 further shows a next I-frame **202** of the INTRA layer, the frame thus being also an independently determined video frame that has been determined without using motion-compensated temporal prediction. The temporal transmission frequency of I-frames depends on many factors relating to video coding, image information contents and the bandwidth to be used, and, depending on the application or application environment, I-frames are transmitted in a video sequence at intervals of 0.5 to 10 seconds, for example. Since the I-frame **202** can be independently decoded, it also forms a separate sub-sequence. Since this is the second sub-sequence in the INTRA-layer, the consecutive numbering of the sub-sequence identifier of the I-frame **202** is 1. Further, since the I-frame **202** also forms a separate sub-sequence, i.e. it is the only video frame in the sub-sequence, its image number is 0. The I-frame **202** can thus be designated with identifier (I.1.0.) Correspondingly, the identifier of the next I-frame on the INTRA layer is (I.2.0.), etc. As a result, only independently determined I-frames in which the image information is not determined using motion-compensated temporal prediction are coded into the first scalability layer, i.e. the INTRA layer. The sub-sequences can also be determined using other kind of numbering or other identifiers, provided that the sub-sequences can be distinguished from one another.

The next scalability layer, which has a layer number 1, for example, and which may be referred to as the base layer, comprises coded, motion-compensated INTER or P-frames typically predicted only from previous image frames, i.e. in this case from the I-frames of an upper INTRA layer. The image information of the first P-frame **204** of the base layer shown in FIG. 2 is determined using the I-frame **200** of the INTRA layer. A P-frame **204** begins the first sub-sequence of the base layer, and therefore the sub-sequence identifier of the P-frame **204** is 0. Further, since the P-frame **204** is the first image frame of the first sub-sequence of the base layer, the image number of the P-frame **204** is 0. The P-frame **204** can thus be identified with (P.0.0).

The temporally succeeding P-frame **206** of the base layer is predicted from the previous P-frame **204**. The P-frames **204** and **206** thus belong to the same sub-sequence, whereby the P-frame **206** also receives the sub-sequence identifier 0. Since the P-frame **206** is the second image frame in the sub-se-

quence 0, the image number of the P-frame 206 is 1, and the P-frame 206 can be identified with (P.0.1).

The scalability layer succeeding the base layer and having the layer number 2, is called enhancement layer 1. This layer comprises coded, motion-compensated P-frames predicted only from previous image frames, in this case either from I-frames of the INTRA layer or P-frames of the base layer. FIG. 2 shows a first image frame 208 and a second image frame 210 of enhancement layer 1, which are both predicted only from the first image frame 200 of the INTRA layer. The P-frame 208 begins the first sub-sequence of enhancement layer 1, the sub-sequence identifier of the P-frame thus being 0. Further, since the P-frame 208 is the first and only image frame in said sub-sequence, the P-frame 208 receives the image number 0. The P-frame 208 can thus be identified with (P.0.0).

Since the second image frame 210 is also predicted only from the first image frame 200 of the INTRA layer, the P-frame 210 begins the second sub-sequence of enhancement layer 1 and the sub-sequence identifier of the P-frame 210 is therefore 1. Since the P-frame 210 is the first image frame in the sub-sequence, the image number of the P-frame 210 is 0. The P-frame can thus be identified with (P.1.0). The temporally succeeding P-frame 212 of enhancement layer 1 is predicted from the previous P-frame 210. The P-frames 210 and 212 thus belong to the same sub-sequence, and therefore the P-frame also receives the sub-sequence identifier 1. The P-frame 212 is the second image frame in the sub-sequence 1, and therefore the P-frame receives the image number 1 and can be identified with (P.1.1).

The temporally fourth image frame 214 of enhancement layer 1 is predicted from the first image frame 204 of the base layer. The P-frame 214 thus begins a third sub-sequence of enhancement layer 1 and therefore the P-frame 214 receives the sub-sequence identifier 2. Further, since the P-frame 214 is the first and only image frame in the sub-sequence, the image number of the P-frame 214 is 0. The P-frame 208 can therefore be identified with (P.2.0).

Also the temporally fifth image frame 216 of enhancement layer 1 is predicted only from the first image frame 204 of the base layer, the P-frame 216 thus beginning the fourth sub-sequence of enhancement layer 1, and the sub-sequence identifier of the P-frame 216 is 3. In addition, since the P-frame 216 is the first one in the sub-sequence in question, the image number of the P-frame 216 is 0. The P-frame 216 can therefore be identified with (P.3.0). The temporally following P-frame 218 of enhancement layer 1 is predicted from the previous P-frame 216. The P-frames 216 and 218 thus belong to the same sub-sequence, and the sub-sequence identifier of the P-frame 218 is also 3. Since the P-frame 218 is the second image frame in the sub-sequence 3, the image number of the P-frame 218 is 1 and the identifier of the P-frame 218 is (P.3.1).

For simplicity and clarity of illustration the above disclosure only relates to I- and P-frames. However, a person skilled in the art will find it apparent that the scalable video coding of the invention can also be implemented using other known image frame types, such as the above described B-frames and at least SI-frames, SP-frames and MH-frames. SI-frames correspond to I-frames, but together with an SP-frame they allow an identical image to be reconstructed. An SP-frame, in turn, is a P-frame subjected to a particular coding that allows an identical image to be reconstructed together with an SI-frame or another SP-frame. SP-frames are typically placed into a video sequence into points where an access point or a scanning point is desired, or where the changing of the coding parameters of the video stream should be possible. The

frames can also be used for error correction and for increasing error tolerance. SP-frames are otherwise similar to ordinary P-frames predicted from previous frames, except that they are defined so that they can be replaced by another video frame of the SP- or SI-type, the result of the decoding of the new frame being identical with the decoding result of the original SP-frame that was in the video stream. In other words, a new SP-frame that is used for replacing the one that was in the video stream is predicted from another sequence or video stream and yet the reconstructed frame has identical contents. SP-frames are described for example in the Applicant's earlier application PCT/FI02/00004.

Similarly as B-frames, macroblocks of MH (Multi Hypothesis) frames, based on motion-compensated prediction, are predicted from two other frames, which are not, however, necessarily located next to an MH-frame. More precisely, the predicted macroblocks are computed as an average of two macroblocks of two other frames. Instead of two frames, MH-frame macroblocks can naturally be also predicted from one other frame. Reference images may change according to macroblock, in other words, all macroblocks in one and the same image are not necessarily predicted using the same frames.

A sub-sequence thus covers a specific period of time in a video sequence. The sub-sequences of the same layer or of different layers may be partly or entirely overlapping. If there are temporally overlapping image frames on the same layer, the frames are interpreted as alternative presentations of the same image content and therefore any mode of image presentation can be used. On the other hand, if there are temporally overlapping image frames on different layers, they form different presentations of the same image content, and therefore presentations differ in image quality, i.e. the quality of image is better on a lower layer.

The above disclosure referring to FIG. 2 illustrates a scalable coding arrangement and a hierarchical structure and numbering of image frames according to a preferred embodiment of the invention. In this embodiment the INTRA-layer only comprises I-frames and the base layer can only be decoded using the information received from the INTRA-layer. Correspondingly, the decoding of enhancement layer 1 typically requires information from both the base layer and the INTRA-layer.

The number of the scalability layers is not restricted to three, as above, but any number of enhancement layers that is considered necessary for producing sufficient scalability may be used. Consequently, the layer number of enhancement layer 2 is four, that of enhancement layer 3 is five, etc. Since some of the image frames in the above example are given the same identifier (e.g. the identifier of both image frames 204 and 208 is (P.0.0)), by including the layer number in the identifier each image frame can be uniquely identified and, at the same time, the dependencies of each image frame on other image frames is preferably determined. Each image frame is thus uniquely identified, the identifier of image frame 204, for example, being (P.1.0.0), or simply (1.0.0) and, correspondingly, that of image 208 being (P.2.0.0), or (2.0.0).

According to a preferred embodiment of the invention, the number of a reference image frame is determined according to a specific, pre-determined alpha-numeric series, for example as an integer between 0 and 255. When the parameter value achieves the maximum value N (e.g. 255) in the series concerned, the determining of the parameter value starts from the beginning, i.e. from the minimum value of the series (e.g. 0). An image frame is thus uniquely identified within a specific sub-sequence up to the point where the same image number is used again. The sub-sequence identifier can

also be determined according to a specific, predetermined arithmetic series. When the value of the sub-sequence identifier achieves the maximum value N of the series, the determining of the identifier starts again from the beginning of the series. However, a sub-sequence cannot be assigned an identifier that is still in use (within the same layer). The series in use may also be determined in another way than arithmetically. One alternative is to assign random sub-sequence identifiers, taking into account that an assigned identifier is not be used again.

A problem in the numbering of image frames arises when the user wishes to start browsing a video file in the middle of a video sequence. Such situations occur for example when the user wishes to browse a locally stored video file backward or forward or to browse a streaming file at a particular point; when the user initiates the playback of a streaming file from a random point; or when a video file that is to be reproduced is detected to contain an error that interrupts the playback or requires the playback to be resumed from a point following the error. When the browsing of a video file is resumed from a random point after previous browsing, discontinuity typically occurs in the image numbering. The decoder typically interprets this as unintentional loss of image frames and unnecessarily tries to reconstruct the image frames suspected as lost.

According to a preferred embodiment of the invention, this can be avoided in the decoder by defining an initiation image in an independently decodable Group of Pictures GOP that is activated at the random point of the video file, and the number of the initiation image is set at zero. This independently decodable image group can thus be a sub-sequence of an INTRA-layer, for example, in which case an I-frame is used as the initiation image, or, if scaling originating from the base layer is employed, the independently decodable image group is a sub-sequence of the base layer, in which case the first image frame of the sub-sequence, typically an I-frame, is usually used as the initiation image. Consequently, when activated at a random point, the decoder preferably sets the identifier of the first image frame, preferably an I-frame, of the independently decodable sub-sequence at zero. Since the sub-sequence to be decoded may also comprise other image frames whose identifier is zero (for example when the above described alpha-numeric series starts from the beginning), the beginning of the sub-sequence, i.e. its first image frame, can be indicated to the decoder for example by a separate flag added to the header field of a slice of the image frame. This allows the decoder to interpret the image numbers correctly and to find the correct image frame that initiates the sub-sequence from the video sequence image frames.

The above numbering system provides only one example of how the unique image frame identification of the invention can be carried out so that interdependencies between the image frames are indicated at the same time. However, video coding methods in which the method of the invention can be applied, such as video coding methods according to the ITU-T standards H.263 and H.26L, employ code tables, which in turn use variable length codes. When variable length codes are used for coding layer numbers, for example, a lower code word index, i.e. a smaller layer number, signifies a shorter code word. In practice the scalable coding of the invention will be used in most cases in such a way that the base layer will consist significantly more image frames than the INTRA-layer. This justifies the use of a lower index, i.e. a smaller layer number, on the base layer than on the INTRA-layer, because the amount of coded video data is thereby advantageously reduced. Consequently, the INTRA-layer is preferably assigned layer number 1 and the base layer is given

layer number 0. Alternatively, the code can be formed by using fewer bits for coding the base layer number than the INTRA-layer number, in which case the actual layer number value is not relevant in view of the length of the code created.

Further, according to a second preferred embodiment of the invention, when the number of the scalability layers is to be kept low, the first scalability layer in particular can be coded to comprise both the INTRA-layer and the base layer. From the point of view of coding hierarchy, the simplest way to conceive this is to leave out the INTRA-layer altogether, and to provide the base layer with coded frames consisting of both independently defined I-frames, the image information of which has not been determined using motion-compensated temporal prediction, and image frames predicted from previous frames, which image frames in this case are motion-compensated P-frames predicted from the I-frames of the same layer. The layer number 0 can thus still be used for the base layer and, if enhancement layers are coded into the video sequence, enhancement layer 1 is assigned layer number 1. This is illustrated in the following, with reference to FIGS. 3a and 3b.

FIG. 3a shows a non-scalable video sequence structure, in which all image frames are placed on the same scalability layer, i.e. the base layer. The video sequence comprises a first image frame 300 which is an I-frame (I.0.0) and which thus initiates a first sub-sequence. The image frame 300 is used for predicting a second image frame 302 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a third image frame 304 of the sub-sequence, i.e. a P-frame (P.0.2), which is in turn used for predicting the next image frame 306, i.e. a P-frame (P.0.3). The video sequence is then provided with an I-frame (I.1.0) coded therein, i.e. an I-frame 308, which thus initiates a second sub-sequence in the video sequence. This kind of non-scalable coding can be used for example when the application employed does not allow scalable coding to be used, or there is no need for it. In a circuit-switched videophone application, for example, channel bandwidth remains constant and the video sequence is coded in real-time, and therefore there is typically no need for scalable coding.

FIG. 3b, in turn, illustrates an example of how scalability can be added, when necessary, to a combined INTRA- and base layer. Here, too, the video sequence base layer comprises a first image frame 310 which is an I-frame (I.0.0) and which initiates a first sub-sequence of the base layer. The image frame 310 is used for predicting a second image frame 312 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a third image frame 314 of the sub-sequence, i.e. a P-frame (P.0.2). Enhancement layer 1, however, is also coded into this video sequence and it comprises a first sub-sequence, the first and only image frame 316 of which is a P-frame (P.0.0), which is predicted from the first image frame 310 of the base layer. The first image frame 318 of a second sub-sequence of the enhancement layer is, in turn, predicted from the second image frame 312 of the base layer, and therefore the identifier of this P-frame is (P.1.0). The next image frame 320 of the enhancement layer is again predicted from the previous image frame 318 of the same layer and, therefore, it belongs to the same sub-sequence, its identifier thus being (P.1.1).

In this embodiment of the invention the sub-sequences of the base layer can be decoded independently, although a base layer sub-sequence may be dependent on another base layer sub-sequence. The decoding of the base layer sub-sequences requires information from the base layer and/or from the second sub-sequence of enhancement layer 1, the decoding of the sub-sequences of enhancement layer 2 requires informa-

13

tion from enhancement layer 1 and/or from the second sub-sequence of enhancement layer 2, etc. According to an embodiment, I-frames are not restricted to the base layer alone, but lower enhancement layers may also comprise I-frames.

The basic idea behind the above embodiments is that a sub-sequence comprises information about all the sub-sequences it is dependent on, i.e. about all sub-sequences that have been used for predicting at least one of the image frames of the sub-sequence in question. However, according to an embodiment it is also possible that a sub-sequence comprises information about all sub-sequences that are dependent on the sub-sequence in question, in other words, about all the sub-sequences in which at least one image frame has been predicted using at least one image frame of the sub-sequence in question. Since in the latter case the dependencies are typically determined temporally forward, image frame buffers can be advantageously utilized in the coding in a manner to be described later.

In all the above embodiments the numbering of the image frames is sub-sequence-specific, i.e. a new sub-sequence always starts the numbering from the beginning. The identification of an individual image frame thus requires the layer number, sub-sequence identifier and image frame number to be determined. According to a preferred embodiment of the invention, the image frames can be independently numbered using consecutive numbering in which successive reference image frames in the coding order are indicated with numbers incremented by one. As regards layer numbers and sub-sequence identifiers, the above-described numbering procedure can be used. This allows each image frame to be uniquely identified, when necessary, without using the layer number and sub-sequence identifier.

This is illustrated with the example shown in FIG. 4a in which the base layer comprises a temporally first I-frame 400 (I.0.0). This frame is used for predicting a first image frame 402 of enhancement layer 1, i.e. (P.0.1), which is then used for predicting a second image frame 404 belonging to the same sub-sequence (with sub-sequence identifier 0), i.e. (P.0.2), which is used for predicting a third image frame 406 of the same sub-sequence, i.e. (P.0.3), which is used for predicting a fourth image frame 408 (P.0.4) and, finally, the fourth frame for predicting a fifth image frame 410 (P.0.5). The temporally next video sequence image frame 412 is located on the base layer, where it is in the same sub-sequence as the I-frame 400, although temporally it is only the seventh coded image frame, and therefore its identifier is (P.0.6). The seventh frame is then used for predicting a first image frame 414 of the second sub-sequence of enhancement layer 1, i.e. (P.1.7), which is then used for predicting a second image frame 416 belonging to the same sub-sequence (with sub-sequence identifier 1), i.e. (P.1.8), which in turn used for predicting a third image frame 418 (P.1.9), the third for predicting a fourth image frame 420 (P.1.10) and, finally, the fourth for predicting a fifth image frame 422 (P.1.11) of the same sub-sequence. Again, the temporally next video sequence image frame 424 is located on the base layer, where it is in the same sub-sequence as the I-frame 400 and the P-frame 412, although temporally it is only the thirteenth coded image frame and therefore its identifier is (P.0.12). For clarity of illustration, the above description of the embodiment does not comprise layer identifiers, but it is apparent that in order to implement scalability, also the layer identifier must be signalled together with the video sequence, typically as part of the image frame identifiers.

FIGS. 4b and 4c show alternative embodiments for grouping the image frames of the video sequence shown in FIG. 4a.

14

The image frames in FIG. 4b are numbered according to sub-sequence, i.e. a new sub-sequence always starts the numbering from the beginning (from zero). FIG. 4c, in turn, employs image frame numbering which corresponds otherwise to that used in FIG. 4a, except that the P-frames of the base layer are replaced by SP-frame pairs to allow for identical reconstruction of image information.

As stated above, the procedure of the invention can also be implemented using B-frames. One example of this is illustrated in FIGS. 5a, 5b and 5c. FIG. 5a shows a video sequence in the time domain, the sequence comprising P-frames P1, P4 and P7, with B-frames placed between them, the interdependencies of the B-frames with regard to temporal predicting being shown with arrows. FIG. 5b shows a preferred grouping of video sequence image frames in which the interdependencies shown in FIG. 5a are indicated. FIG. 5b illustrates sub-sequence-specific image frame numbering in which a new sub-sequence always starts the numbering of the image frames from zero. FIG. 5c, in turn, illustrates image frame numbering, which is consecutive in the order of temporal prediction, wherein the following reference frame always receives the next image number as the previously encoded reference frame. The image frame (B1.8) (and (B2.10)) does not serve as a reference prediction frame to any other frame, therefore it does not affect the image frame numbering.

The above examples illustrate different alternatives of how scalability of video sequence coding can be adjusted by using the method of the invention. From the point of view of the terminal device reproducing the video sequence, the more scalability layers are available, or the more scalability layers it is capable of decoding, the better the image quality. In other words, increase in the amount of image information and in the bit rate used for transferring the information improves the temporal or spatial resolution, or the spatial quality of the image data. Correspondingly, a higher number of scalability layers also sets considerably higher demands on the processing capacity of the terminal device performing decoding.

In addition, the above examples illustrate the advantage gained by using sub-sequences. With image frame identifiers, the dependencies of each image frame from other image frames in the sub-sequence are indicated in an unambiguous manner. A sub-sequence thus forms an independent whole that can be left out of a video sequence, when necessary, without affecting the decoding of subsequent image frames of the video sequence. In that case, only the image frames of the sub-sequence in question and of those sub-sequences on the same and/or lower scalability layers dependent on it are not decoded.

The image frame identifier data transmitted together with the video sequence are preferably included in the video sequence header fields or in the header fields of the transfer protocol to be used for transferring the video sequence. In other words, the identifier data of predicted image frames are not included in the image data of the coded video sequence, but always into the header fields, whereby the dependencies of the image frames can be detected without decoding the images of the actual video sequence. The identifier data of the image frames can be stored for example in the buffer memory of the streaming server as the video sequence is being coded for transmission. In addition, the sub-sequences can be independently decoded on each scalability layer, because the image frames of a sub-sequence are not dependent on other sub-sequences of the same scalability layer.

According to an embodiment of the invention, the image frames comprised by a sub-sequence may thus depend also on other sub-sequences of the same scalability layer. This dependency must then be signalled for example to the streaming

server carrying out traffic shaping, because interdependent sub-sequences located on the same layer cannot be separately removed from a video sequence to be transmitted. A preferred way to carry out the signalling is to include it in the image frame identifiers to be transmitted, for example by listing the layer-sub-sequence pairs the sub-sequence in question depends on. This also provides a preferred way of indicating dependency from another sub-sequence of the same scalability layer.

The above examples illustrate a situation where image frames are temporally predicted from previous image frames. In some coding methods, however, the reference picture selection has been further extended to also include the predicting of the image information of image frames from temporally succeeding image frames. Reference picture selection offers most diversified means for creating different temporally scalable image frame structures and allows the error sensitivity of the video sequence to be reduced. One of the coding techniques based on reference picture selection is INTRA-frame postponement. The INTRA-frame is not placed into its temporally "correct" position in the video sequence, but its position is temporally postponed. The video sequence image frames that are between the "correct" position of the INTRA-frame and its actual position are predicted temporally backward from the INTRA-frame in question. This naturally requires that uncoded image frames be buffered for a sufficiently long period of time so that all image frames that are to be displayed can be coded and arranged into their order of presentation. INTRA-frame transfer and the associated determining of sub-sequences in accordance with the invention are illustrated in the following with reference to FIG. 6.

FIG. 6a shows a video sequence part in which the INTRA-frame comprises a single I-frame 600, which is temporally transferred to the position shown in FIG. 6, although the "correct" position of the I-frame in the video sequence would have been at the first image frame. The video sequence image frames between the "correct" position and the real position 600 are thus temporally predicted backward from the I-frame 600. This is illustrated by a sub-sequence coded into enhancement layer 1 and having a first temporally backward predicted image frame 602, which is a P-frame (P.0.0). This frame is used for temporally predicting a previous image frame 604, i.e. a P-frame (P.0.1), which is used in turn for predicting an image frame 606, i.e. a P-frame (P.0.2), and, finally, the frame 606 for predicting an image frame 608, i.e. a P-frame (P.0.3), which is at the position that would have been the "correct" position of the I-frame 600 in the video sequence. Correspondingly, the I-frame 600 on the base layer is used for temporally forward prediction of a sub-sequence comprising four P-frames 610, 612, 614 and 616, i.e. P-frames (P.0.0), (P.0.1), (P.0.2) and (P.0.3).

The fact that in this example backward predicted image frames are placed on a lower layer than forward predicted image layers indicates that for purposes of illustration, backward predicted image frames are in this coding example considered subjectively less valuable than forward predicted image frames. Naturally the sub-sequences could both be placed on the same layer, in which case they would be considered equal, or a backward predicted sub-sequence could be on the upper layer, in which case it would be considered subjectively more valuable.

FIGS. 6b and 6c show some alternatives for coding a video sequence according to FIG. 6a. In FIG. 6b both forward and backward predicted sub-sequences are placed on the base layer, the I-frame being only located on the INTRA-layer. The forward predicted sub-sequence on this layer is thus the

second sub-sequence and its sub-sequence identifier is 1. In FIG. 6c, in turn, an I-frame and a forward predicted sub-sequence based on it are located on the base layer, while a backward predicted sub-sequence is located on enhancement layer 1.

Moreover, according to a preferred embodiment of the invention, the above-described scalability can be utilized for coding what is known as a scene transition into a video sequence. Video material, such as news reports, music videos and movie trailers, often comprise rapid cuts between separate image material scenes. Sometimes the cuts are abrupt, but often a procedure known as scene transition is used in which transfer from one scene to another takes place by dimming, wiping, mosaic dissolving or scrolling the image frames of a previous scene, and, correspondingly, by presenting those of a later scene. From the point of view of coding efficiency, the video coding of a scene transition is often most problematic, because the image frames appearing during the scene transition comprise information on the image frames of both the terminating and the initiating scene.

A typical scene transition, fading, is carried out by gradually reducing the intensity or luminance of the image frames of a first scene to zero, while gradually increasing the intensity of the image frames of a second scene to its maximum value. This scene transition is referred to as cross-faded scene transition.

Generally speaking, a computer-made image can be thought of as consisting of layers, or image objects. Each object can be defined with reference to at least three information types: the structure of the image object, its shape and transparency, and the layering order (depth) in relation to the background of the image and to other image objects. Shape and transparency are often determined using what is known as an alpha plane, which measures opacity and the value of which is usually determined separately for each image object, possibly excluding the background, which is usually determined as non-transparent. The alpha plane value of a non-transparent image object, such as the background, can thus be set at 1.0, whereas the alpha plane value of a fully transparent image object is 0.0. The values in between define the intensity of the visibility of a specific image object in a picture in proportion to the background and to other, at least partly overlapping, image objects that have a higher depth value than the image object in question.

The superimposition of image objects in layers according to their shape, transparency and depth position is referred to as scene composition. In practice the procedure is based on the use of weighted averages. First, the image object that is closest to the background, i.e. deepest according to its depth position, is placed onto the background and a combined image is formed of the two. The pixel values of the combined image are formed as an average weighted by the alpha plane values of the background image and the image object in question. The alpha plane value of the combined image is then set at 1.0, after which it serves as a background image for the next image object. The process continues until all image objects are attached to the image.

In the following, a procedure according to a preferred embodiment of the invention will be described in which video sequence scalability layers are combined with the above described image objects of image frames and their information types to provide a scene transition with scalable video coding that also has good compression efficiency.

This embodiment of the invention is illustrated in the following by way of example and in a simplified manner by using cross-faded scene transition, on one hand, and abrupt scene transition, on the other hand, as examples. The image

17

frames to be displayed during a scene transition are typically formed of two superimposed image frames, a first image frame comprising a first image scene and a second image frame a second scene. One of the image frames serves as the background image and other, which is referred to as a foreground image, is placed on top of the background image. The opacity of the background image, i.e. its non-transparency value, is constant. In other words, its pixel-specific alpha plane values are not adjusted.

In this embodiment of the invention, the background and foreground images are both defined according to scalability layer. This is illustrated in FIG. 7, which shows an example of how image frames of two different scenes can be placed on scalability layers during a scene transition of the invention. FIG. 7 shows a first image frame 700 of a first (terminating) scene positioned on the base layer. The image frame 700 may be either an I-frame containing image information that has not been determined using motion-compensated temporal predicting, or it may be a P-frame that is a motion-compensated image frame predicted from previous image frames. The coding of a second (initiating) scene starts during the temporally following image frame and, according to the invention, the image frames of the scene are also placed on the base layer. Remaining image frames 702, 704 of the second (terminating) scene are then placed on enhancement layer 1. These image frames are typically P-frames.

In this embodiment, the image frames of the second (initiating) scene are thus placed on the base layer, at least for the duration of the scene transition. The first image frame 706 of the scene is typically an I-frame, and it is used for temporally predicting the succeeding image frames of the scene. Consequently, the succeeding image frames of the second scene are temporally predicted frames, typically P-frames, such as frames 708 and 710 shown in FIG. 7.

According to a preferred embodiment of the invention, this placing of image frames on scalability layers can be used for implementing a cross-faded scene transition by determining the image layer that is on the base layer always as a background image of maximum opacity (100%), or non-transparency value. During a scene transition, image frames located on enhancement layers are placed onto the background image and their opacity is adjusted for example by means of suitable filters such that the frames gradually change from non-transparent to transparent.

In the video sequence of FIG. 7, there are no image frames on the lower scalability layers during the first base layer image frame 700. For this time instant, the first image frame 700 is only coded into the video sequence.

The next image frame 706 of the base layer initiates a new (second) scene, during which the image frame 706 is provided with depth positioning that places it as the background image, and its opacity value is set to the maximum. Temporally simultaneously with the image frame 706 of the base layer, there is an image frame 702 of a terminating (first) scene on enhancement layer 1. To allow a cross-faded scene transition to be produced, the transparency of the frame 702 must be increased. The example of FIG. 7 assumes that the opacity of the image frame 702 is set at 67% and, in addition, the image frame 702 is provided with depth positioning that determines it as a foreground image. For this time instant, an image combining the image frames 706 and 702 is coded into the video sequence, image 706 being visible as a weaker image on the background and image 702 as a stronger image at the front, because its opacity value is essentially high (67%).

During the temporally following image frame, there is a second image frame 708 of the second scene on the base layer,

18

the frame 708 being thus correspondingly provided with depth positioning determining it as a background image, and its opacity value is set to the maximum. Enhancement layer 1 further comprises the last image frame 704 of a temporally simultaneously terminating (first) scene, the opacity value of the frame being set at 33% and, in addition, the image frame 704 being provided with depth positioning that determines it as a foreground image as well. Consequently, for this time instant, an image combined of the image frames 708 and 704 is coded into the video sequence, the image 708 being displayed as a stronger image on the background and the image 704 as a weaker image on the foreground, because the opacity value of the image 704 is no longer more than 33%.

During the temporally following image frame, the base layer comprises a third image frame 710 of the second scene. Since the first scene has terminated, only the image frame 710 is coded into the video sequence, and the displaying of the second scene continues from the frame 710.

The above disclosure describes, by way of example, the positioning of image frames according to the invention on scalability layers to implement cross-faded scene transition in a manner that is advantageous from the point of view of coding efficiency. However, it is possible that when a video sequence is being transmitted or decoded, a situation arises in which the bit rate of the video sequence must be adjusted according to the maximum value of the bandwidth and/or terminal device decoding rate available for data transfer. This kind of bit rate control causes problems when the scene transition is to be implemented using prior art video coding methods.

A preferred embodiment of the present invention now allows one or more scalability layers, or independently decodable sub-sequences included in them, to be removed from a video sequence, whereby the bit rate of the video sequence can be decreased and yet, at the same time, the video sequence can be decoded without reducing image frequency. In the image frame positioning according to FIG. 7, this can be implemented by removing enhancement layer 1 from the video sequence. The video sequence is thus only used for displaying the image frames 700, 706, 708 and 710 of the base layer. In other words, a direct transition from the first (terminating) scene to the second (initiating) scene takes place in the form of an abrupt scene transition, i.e. directly from the image frame 700 of the first scene into the I-image frame 706 that initiates the second scene. The transition is thus not a cross-faded scene transition but an abrupt scene transition. Nevertheless, the scene transition can be carried out in an advantageous manner without affecting the quality of the video sequence image, and the viewer usually does not experience an abrupt scene transition carried out instead of a cross-faded scene transition in any way disturbing or faulty. On the contrary, since the prior art implementation does not allow scalability layers to be removed, scene transition would often require image frequency to be reduced, which the viewer would find jerky and disturbing.

The invention thus provides a preferred means for carrying out multimedia data traffic shaping in a streaming server comprising information about the different sub-sequences of a video sequence: their average bit rate, location in relation to the entire video sequence, duration and their interdependencies regarding the layers. The streaming server also determines the maximum value of the bandwidth available for the data transfer and/or the decoding rate of the terminal device. On the basis of this information, the streaming server decides how many scalability layers and which sub-sequences are transmitted in the video sequence. Bit rate control can thus be carried out, when necessary, by making first a rough adjust-

ment of the number of the scalability layers, after which finer sub-sequence-specific adjustment can be easily carried out. At its simplest, bit rate control means making sub-sequence-specific decisions on whether a particular sub-sequence will be added to a video sequence or removed from it. In case of removal it is advisable to remove entire sub-sequences from a video sequence, because the removal of separate images may cause errors in other images of the same sub-sequence. For the same reason, all sub-sequences of a lower enhancement layer should be left out if they are dependent on the removed sub-sequence of a higher layer. If there are interdependent sub-sequences on one and the same scalability layer, sub-sequences dependent on an earlier sub-sequence must be removed if the earlier sub-sequence is removed.

If the image frame identifier data are added to a video sequence that is to be transmitted, traffic shaping can also be carried out in a telecommunications network element to be used for the transfer of the video sequence, for example in an Internet router, in different gateways, or at a base station or base station controller of a mobile communications network. For the network element to be able to maintain and process the sub-sequence information, it must have extra memory and processing capacity. For this reason traffic shaping that is to be carried out in the network is perhaps most probably executed using simple processing methods, such as the Diff-Serv, i.e. differentiated services, procedure that is supported by some IP-based networks. In the DiffServ method, each IP data packet is assigned a priority, whereby data packets of a higher priority are relayed faster and more reliably to the recipient than packets of a lower priority. This is advantageously applied to the scalability of the invention by determining not only scalability-layer-specific, but also sub-sequence-specific priorities, which enables a highly advanced prioritisation.

There are many alternatives for adding image frame identifier data to a video sequence that is to be transmitted. In addition, it is also possible not to include any identifier data into the video sequence, in which case traffic shaping is only carried out at the streaming server. The identifier data can be included in the header fields of a video sequence, or in the header fields of the transfer protocol to be used, such as RTP (Real Time Protocol). According to a preferred embodiment, the identifier data can be transferred using a Supplemental Enhancement Information (SEI) mechanism. SEI provides a data delivery mechanism that is transferred synchronously with the video data content, thus assisting in the decoding and displaying of the video sequence. The SEI mechanism, particularly when used for transferring layer and sub-sequence information, is disclosed more in detail in the ITU-T standard document ITU-T Rec. H.264 (ISO/IEC 14496-10:2002), Annex D. In the cases, wherein a separate transfer protocol or mechanism is used for identifier data transfer, traffic shaping can be carried out also at one of the network elements of the transfer path. In addition, the receiving terminal device can control the decoding.

If the encoder or decoder supports reference picture selection, video sequence coding requires that decoded image frames be buffered before the coding so as to allow the relationships between different image frames to be temporally predicted from one or more other image frames. Image frame buffering can be arranged at least in two different ways, either as sliding windowing or as adaptive buffer memory control. In sliding windowing, M image frames that were coded last are used as a buffer. The frames in the buffer memory are in a decoded and reconstructed form, which allows them to be used as reference images in the coding. As the coding proceeds, the image frame buffering functions on the basis of the

FIFO principle (First-In-First-Out). Images that are not used as reference images, such as conventional B-images, do not need to be stored in the buffer. Alternatively, the buffering can be also be implemented as adaptive buffer memory control, in which case the image buffering is not restricted to the FIFO principle, but image frames that are not needed can be removed from the buffer in the middle of the process, or, correspondingly, some image frames can be stored in the buffer for a longer period of time, if they are needed as reference images for later image frames. A known reference picture selection is implemented by indexing image frames that are in the buffer memory into a specific order, the image indices being then used to refer to an image in connection with motion-compensation, for example. This indexing method generally provides better compression efficiency compared to using image numbers, for example, for referring to a specific image when motion-compensation reference images are to be signalled.

The above reference image indexing method is sensitive to transfer errors, because the buffers of the sender's encoder and the recipient's decoder must contain mutually corresponding reconstructed images in identical order to ensure that the encoder and decoder both form the same indexing order. If the image frames are indexed in different order in the buffers of the encoder and the decoder, an incorrect reference image may be used in the decoder. To prevent this, it is essential that the decoder can be controlled to take into account image frames and sub-sequences that the encoder has intentionally removed from the video sequence. In that case the image frame numbering may comprise gaps, which the decoder typically interprets as errors and tries to reconstruct the image frames interpreted as lost. For this reason, it is essential that the encoder is capable to inform the decoder that the discontinuities in the image numbering of the transmitted image frames are intentional.

In response to this, and provided that sliding windowing is used for buffering the image frames, the decoder enters into the buffer memory a number of image frames, the contents of which may be fully random, corresponding to the missing image numbers. These random image frames are then designated by an identifier "invalid" to indicate that the frames in question do not belong to the actual video sequence, but are only filler frames entered for purposes of buffer memory management. A filler frame can naturally be implemented using only memory indicators, i.e. no data is preferably entered into the buffer memory, but memory management is used merely to store a reference to a generic "invalid" frame. The entering of the image frames of the actual video sequence continues from the correct image frame number after the number of filler frames indicated by the missing image numbers has been entered into the buffer, which allows the buffer memories of the encoder and the decoder to be kept preferably in synchronism. If during decoding a reference to an image number is detected which is then found to indicate a filler frame located in the buffer, error correction actions are initiated in the decoder to reconstruct the actual reference image, for example by asking the encoder to re-transmit the reference image in question.

Further, the procedure of the invention allows separate buffer memories to be used on the different scalability layers, or, correspondingly, sub-sequence-specifically. Each scalability layer may thus have a separate buffer memory that is conceptually separate and functions on the basis of the sliding window principle. Similarly, each sub-sequence may also be provided with a conceptually separate buffer memory that also functions on the basis of the sliding window principle. This means that the buffer memory is always emptied when a

sub-sequence terminates. Separate buffer memories can be used in a preferred manner for reducing the need for signaling in certain situations in which ordinary sliding window buffering would be inadequate and actively adaptive buffer memory management would need to be used instead.

The H.26L standard defines a picture order count as a picture position in output order. The decoding process specified in the H.26L standard uses picture order counts to determine default index orderings for reference pictures in B slices, to represent picture order differences between frames and fields for vector scaling in motion vector prediction and for implicit mode weighted prediction in B slices, and to determine when successive slices in decoding order belong to different pictures. The picture order count is coded and transmitted for each picture.

In one embodiment of the invention, the decoder uses the picture order count to conclude that pictures are temporally overlapping, i.e., pictures that have an equal picture order count are temporally overlapping. Preferably, the decoder outputs only the picture on the highest received layer. In the absence of layer information, the decoder concludes that the latest temporally overlapping picture in decoding order resides on highest received layer.

The above disclosure describes a procedure for coding video frames for the purpose of producing a scalable, compressed video sequence. The actual procedure is carried out in a video encoder, such as the compressor **108** of FIG. 1, which may be any known video encoder. For example a video encoder according to the ITU-T recommendation H.263 or H.26L may be used, the video encoder being arranged to form, in accordance with the invention, a first sub-sequence into a video sequence, at least part of the sub-sequence being formed by coding I-frames; to form at least a second sub-sequence into the video sequence, at least part of the sub-sequence being formed by coding at least P- or B-frames, and at least one video frame of the second sub-sequence being predicted from at least one video frame of the first sub-sequence; and to determine into the video sequence the identification data of at least the video frames of the second sub-sequence.

According to the procedure of the invention, each sub-sequence of a particular scalability layer is preferably independently decodable, naturally taking into account dependencies from higher scalability layers and possibly other sub-sequences of the same scalability layer. A scalably compressed video sequence such as the one described above can thus be decoded by decoding a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding at least I-frames, and by decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed by coding at least P- or B-frames, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence, and by determining the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence, and by reconstructing at least part of the video sequence on the basis of the sub-sequence dependencies.

The actual decoding takes places in the video decoder, such as the decompressor **118** of FIG. 1, which may be any known video decoder. For example, a low bit rate video decoder according to the ITU-T recommendation H.263 or H.26L may be used, which in this invention is arranged to decode a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding I-frames; to decode at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed

by coding at least P- or B-frames and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence. The video decoder is arranged to determine the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence and to reconstruct at least part of the video sequence on the basis of the dependencies of the sub-sequences.

An essential aspect in the operation of the streaming system of the invention is that the encoder and decoder are positioned at least so that the encoder is operationally connected to the streaming server and the decoder is operationally connected to the receiving terminal device. However, the different elements of the streaming system, terminal devices in particular, may include functionalities that allow two-way transfer of multimedia files, i.e. transmission and reception. The encoder and decoder can thus be implemented in the form of what is known as a video codec integrating both encoder and decoder functionalities.

It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by hardware solutions or as a combination of hardware and software. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

Another alternative is to implement the invention as a video signal comprising a scalably compressed video sequence which in turn comprises video frames coded according to at least a first and a second frame format, the video frames according to the first frame format being independent of other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames. According to the invention, the video signal in question comprises at least a first sub-sequence, at least part of which has been formed by coding at least video frames of the first frame format; at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format; and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and at least one data field that determines video frames belonging to the second sub-sequence.

It is apparent to a person skilled in the art that as technology advances the basic idea of the invention can be implemented in various ways. The invention and its embodiments are therefore not restricted to the above examples, but they may vary within the scope of the claims.

The invention claimed is:

1. A method for encoding a video sequence comprising an independent sequence of image frames, wherein all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence, the method comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence;
encoding identifier values for the image frames according to a numbering scheme; and

23

resetting the identifier value for the indicated first image frame of the independent sequence.

2. A method according to claim 1, further comprising: encoding the indication into the video sequence as a separate flag included in the header of a slice.

3. A method according to claim 1, further comprising: encoding into the video sequence an identifier value for the independent sequence.

4. A video encoder comprising at least one processor and at least one memory including computer program code, the at least one memory and the computer program code configured to, with the at least one processor, cause the video encoder to encode a video sequence comprising an independent sequence of image frames, wherein all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence by causing the video encoder to at least:

encode into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence;

encode identifier values for the image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of the independent sequence.

5. A video encoder according to claim 4, wherein the video encoder is configured to encode the indication into the video sequence as a separate flag included in the header of a slice.

6. A video encoder according to claim 4, wherein the video encoder is configured to encode into the video sequence an identifier value for the independent sequence.

7. A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for encoding a video sequence comprising an independent sequence of image frames, wherein all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence, the computer program product comprising:

a computer program code for encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence;

a computer code for encoding identifier values for the image frames according to a numbering scheme; and

a computer code for resetting the identifier value for the indicated first image frame of the independent sequence.

8. A method for decoding a compressed video sequence, the method comprising:

decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, wherein all motion-compensated temporal prediction references of

24

the independent sequence refer only to image frames within said independent sequence;

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

decoding identifier values for image frames according to a numbering scheme; and

resetting the identifier value for the indicated first image frame of the independent sequence.

9. A method according to claim 8, wherein the indication is a separate flag included in the header of a slice.

10. A video decoder comprising at least one processor and at least one memory including computer program code, the at least one memory and the computer program code configured to, with the at least one processor, cause the video decoder to decode a compressed video sequence, by causing the video decoder to at least:

decode from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, wherein all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence;

start the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame; and

decode identifier values for image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of the independent sequence.

11. A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, the computer program product comprising:

a computer program code for decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, wherein all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence;

a computer program code for starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

a computer program code for decoding identifier values for image frames according to a numbering scheme; and

a computer program code for resetting the identifier value for the indicated first image frame of the independent sequence.

(57) **ABSTRACT**

A method for encoding sequences of pictures into a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices. The method comprises defining parameters in a sequence parameter set; defining parameters in a picture parameter set; and defining at least one picture parameter in a slice header. The picture parameter remains unchanged at least in all slice headers of one picture.

METHOD FOR CODING SEQUENCES OF PICTURES

FIELD OF THE INVENTION

The present invention relates to a method for coding sequences of pictures into a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices. The invention further relates to a method for decoding sequences of pictures from a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices. The invention also relates to a system, transmitting device, receiving device, an encoder, a decoder, an electronic device, a software program, a storage medium, and a bitstream.

BACKGROUND OF THE INVENTION

Published video coding standards include ITU-T H.261, ITU-T H.263, ISO/IEC MPEG-1, ISO/IEC MPEG-2, and ISO/IEC MPEG-4 Part 2. These standards are herein referred to as conventional video coding standards.

There is a standardization effort going on in a Joint Video Team (JVT) of ITU-T and ISO/IEC. The work of JVT is based on an earlier standardization project in ITU-T called H.26L. The goal of the JVT standardization is to release the same standard text as ITU-T Recommendation H.264 and ISO/IEC International Standard 14496-10 (MPEG-4 Part 10). The draft standard is referred to as the JVT coding standard in this application, and the codec according to the draft standard is referred to as the JVT codec.

Video Communication Systems

Video communication systems can be divided into conversational and non-conversational systems. Conversational systems include video conferencing and video telephony. Examples of such systems include ITU-T Recommendations H.320, H.323, and H.324 that specify a video conferencing/telephony system operating in ISDN, IP, and PSTN networks respectively. Conversational systems are characterized by the intent to minimize the end-to-end delay (from audio-video capture to the far-end audio-video presentation) in order to improve the user experience.

Non-conversational systems include playback of stored content, such as Digital Versatile Disks (DVDs) or video files stored in a mass memory of a playback device, digital TV, and streaming.

In the following, some terms relating to video information are defined for clarity. A frame contains an array of luma samples and two corresponding arrays of chroma samples. A frame consists of two fields, a top field and a bottom field. A field is an assembly of alternate rows of a frame. A picture is either a frame or a field. A coded picture is either a coded field or a coded frame. In the JVT coding standard, a coded picture consists of one or more slices. A slice consists of an integer number of macroblocks, and a decoded macroblock corresponds to a 16×16 block of luma samples and two corresponding blocks of chroma samples. In the JVT coding standard, a slice is coded according to one of the following coding types: I (intra), P (predicted), B (bi-predictive), SI (switching intra), SP (switching predicted). A coded picture is allowed to contain slices of different types. All types of pictures can be used as reference pictures for P, B, and SP slices. The instantaneous decoder refresh (IDR) picture is a particular type of a coded picture including only slices with I or SI slice types. No subsequent picture can refer to pictures that are earlier than the IDR picture in decoding order. In some video coding standards, a coded video sequence is an entity containing all pictures in the bitstream before the end of a sequence mark. In the JVT coding standard, a coded video sequence is an entity

containing all coded pictures from an IDR picture (inclusive) to the next IDR picture (exclusive) in decoding order. In other words, a coded video sequence according to the JVT coding standard corresponds to a closed group of pictures (GOP) according to MPEG-2 video.

Conventional video coding standards have specified a structure for an elementary bitstream, i.e., a self-containing bitstream that decoders can parse. The bitstream has consisted of several layers, typically including several of the following: a sequence layer, a group of pictures (GOP) layer, a picture layer, a slice layer, a macroblock layer, and a block layer. The bitstream for each layer typically comprises a header and associated data.

The codec specification itself distinguishes conceptually between a video coding layer (VCL), and the network abstraction layer (NAL). The VCL contains the signal processing functionality of the codec, things such as transform, quantization, motion search/compensation, and the loop filter. It follows the general concept of most of today's video codecs, a macroblock-based coder that utilizes inter picture prediction with motion compensation, and transform coding of the residual signal. The output of the VCL are slices: a bit string that contains the macroblock data of an integer number of macroblocks, and the information of the slice header (containing the spatial address of the first macroblock in the slice, the initial quantization parameter, and similar). Macroblocks in slices are ordered in scan order unless a different macroblock allocation is specified, using the so-called Flexible Macroblock Ordering syntax. In-picture prediction is used only within a slice.

The NAL encapsulates the slice output of the VCL into Network Abstraction Layer Units (NALUs), which are suitable for the transmission over packet networks or the use in packet oriented multiplex environments. All NAL units relating to a certain picture form an access unit. JVT's Annex B defines an encapsulation process to transmit such NALUs over byte-stream oriented networks. A stream of NAL units does not form an elementary bitstream as such because there are no start codes in NAL units, but rather NAL units have to be framed with start codes according to Annex B of the JVT coding standard to form an elementary bitstream.

The optional reference picture selection mode of H.263 and the NEWPRED coding tool of MPEG-4 Part 2 enable selection of the reference frame for motion compensation per each picture segment, e.g., per each slice in H.263. Furthermore, the optional Enhanced Reference Picture Selection mode of H.263 and the JVT coding standard enable selection of the reference frame for each macroblock separately.

Parameter Set Concept

The JVT coding standard contains headers at slice layer and below, but it does not include picture, GOP, or sequence headers. Instead, a concept of a parameter set, introduced in ITU-T document VCEG-N55, replaces such headers. An instance of a parameter set includes all picture, GOP, and sequence level data such as picture size, display window, optional coding modes employed, macroblock allocation map, and others. Each parameter set instance includes a unique identifier. Each slice header includes a reference to a parameter set identifier, and the parameter values of the referred parameter set are used when decoding the slice. Parameter sets decouple the transmission and decoding order of infrequently changing picture, GOP, and sequence level data from sequence, GOP, and picture boundaries. Parameter sets can be transmitted out-of-band using a reliable transmission protocol as long as they are decoded before they are referred. If parameter sets are transmitted in-band, they can be repeated multiple times to improve error resilience compared to conventional video coding schemes. Preferably the parameter sets are transmitted at a session set-up time. However, in

some systems, mainly broadcast ones, reliable out-of-band transmission of parameter sets is not feasible, but rather parameter sets are conveyed in-band in Parameter Set NAL units.

In order to be able to change picture parameters (such as the picture size), without having the need to transmit Parameter Set updates synchronously to the slice packet stream, the encoder and decoder can maintain a list of more than one Parameter Set. Each slice header contains a codeword that indicates the Parameter Set to be used.

This mechanism allows decoupling of the transmission of the Parameter Sets from the packet stream, and transmit them by external means, e.g. as a side effect of the capability exchange, or through a (reliable or unreliable) control protocol. It may even be possible that they are never transmitted but are fixed by an application design specification.

There are some disadvantages with pre-defined parameter sets. First, if there is a need to transmit many parameter set instances in the beginning of a session, the out-of-band method may become overburdened or the beginning latency of the session will be too long. Second, in systems lacking feasible mechanisms for reliable out-of-band transmission of parameter sets, in-band transport of Parameter Set NAL units is not reliable. Third, for broadcast applications, since the parameter sets information should be transmitted frequently to allow new users join during the broadcast process, redundant transmission of all the active parameter set instances is costly from bit-rate point of view.

Transmission of Multimedia Streams

A multimedia streaming system consists of a streaming server and a number of players, which access the server via a network. The network is typically packet-oriented and provides little or no means to guarantee quality of service. The players fetch either pre-stored or live multimedia content from the server and play it back in real-time while the content is being downloaded.

The type of communication can be either point-to-point or multicast. In point-to-point streaming, the server provides a separate connection for each player. In multicast streaming, the server transmits a single data stream to a number of players, and network elements duplicate the stream only if it is necessary.

When a player has established a connection to a server and requested for a multimedia stream, the server begins to transmit the desired stream. The player does not start playing the stream back immediately, but rather it typically buffers the incoming data for a few seconds. Herein, this buffering is referred to as initial buffering. Initial buffering helps to maintain pauseless playback, because, in case of occasional increased transmission delays or network throughput drops, the player can decode and play buffered data.

SUMMARY OF THE INVENTION

One aim of the present invention is to avoid the problems of prior art and provide a more efficient method to transmit parameters relating to picture information. According to an advantageous embodiment of the present invention, the following method for parameter set signalling is provided:

A relatively large number of frequently used parameter set instances and their IDs are pre-defined and stored both in an encoding device and in a decoding device. When the communication starts, these pre-defined parameter sets need not be transmitted. Only the parameter sets not included in the pre-defined ones have to be transmitted, preferably at the session beginning, or transmitted in parameter set NAL units later if

necessary. The system could include a definition of default parameter sets for each profile and level.

According to the invention, there exist at least two kinds of parameter sets: one for the sequence (sequence parameter set) and one for the pictures (picture parameter set).

For applications without feedback channels (digital TV) or with feedback channels of very limited use (e.g. multicast streaming with a huge number of receivers), the set of pre-defined parameter sets should be as complete as possible, from the point of view of possible systems and application scenarios. Therefore, it may be possible that no parameter sets need to be transmitted. Once a parameter set NAL unit is needed, it should be transmitted multiple times to ensure that it is correctly received.

Another inventive concept of the present invention splits the parameter set structure to multiple parameter set structures according to the persistency and target of parameters. In particular, the invention includes the concepts of sequence parameter set and picture parameter set. The selection of a correct parameter set for each parameter depends on the probable and allowed changing rate of the parameter. Parameters whose value may change in every slice or whose value is likely to change in every picture, are included in the slice header. If it is probable that a parameter remains unchanged in multiple pictures but is allowed to change in every picture, such parameter is included in a picture parameter set. Such parameters which are not allowed to change in a coded video sequence are included in the sequence parameter set. Some non-restrictive examples of such parameters are picture order count, frame number and identifier of an independently decodable picture.

In the following description the invention is described by using encoder-decoder based system, but it is obvious that the invention can also be implemented in systems in which the video signals are stored. The stored video signals can be either uncoded signals stored before encoding, encoded signals stored after encoding, or decoded signals stored after encoding and decoding process. For example, an encoder produces bitstreams. A file system receives audio and/or video bitstreams which are encapsulated e.g. in decoding order and stored as a file.

The encoding method according to the present invention is primarily characterized in that the method comprises:

- defining parameters in a sequence parameter set;
- defining parameters in a picture parameter set; and
- defining at least one picture parameter in a slice header, the picture parameter remaining unchanged at least in all slice headers of one picture.

The decoding method according to the present invention is primarily characterized in that the method comprises:

- recognizing a sequence parameter set and forming at least one sequence parameter pertaining to a sequence using the parameter set;
- recognizing a picture parameter set and forming at least one first picture parameter pertaining to a picture using the parameter set; and
- forming at least one second picture parameter using information of a slice header, the at least one second picture parameter remaining unchanged at least in all slice headers of one picture

using the at least one second picture parameter in decoding.

The encoder according to the present invention is primarily characterized in that it comprises:

- means for defining parameters in a sequence parameter set;
- means for defining parameters in a picture parameter set; and

5

means for defining at least one picture parameter in a slice header, the picture parameter remaining unchanged at least in all slice headers of one picture.

The decoder according to the present invention is primarily characterized in that the it comprises:

means for recognizing a sequence parameter set and forming at least one sequence parameter pertaining to a sequence using the parameter set;

means for recognizing a picture parameter set and forming at least one first picture parameter pertaining to a picture using the parameter set;

means for forming at least one second picture parameter using information of a slice header, the at least one second picture parameter remaining unchanged at least in all slice headers of one picture; and

means for using the at least one second picture parameter in decoding.

The system according to the present invention is primarily characterized in that the encoder comprises:

means for defining parameters in a sequence parameter set;

means for defining parameters in a picture parameter set; and

means for defining at least one picture parameter in a slice header, the picture parameter remaining unchanged at least in all slice headers of one picture;

and the decoder comprises:

means for recognizing a sequence parameter set and forming at least one sequence parameter pertaining to a sequence using the parameter set;

means for recognizing a picture parameter set and forming at least one first picture parameter pertaining to a picture using the parameter set;

means for forming at least one second picture parameter using information of a slice header, the at least one second picture parameter remaining unchanged at least in all slice headers of one picture; and

means for using the at least one second picture parameter in decoding.

The transmitting device according to the present invention is primarily characterized in that the encoder comprises:

means for defining parameters in a sequence parameter set; means for defining parameters in a picture parameter set; and

means for defining at least one picture parameter in a slice header, the picture parameter remaining unchanged at least in all slice headers of one picture.

The receiving device according to the present invention is primarily characterized in that the decoder comprises:

means for recognizing a sequence parameter set and forming at least one sequence parameter pertaining to a sequence using the parameter set;

means for recognizing a picture parameter set and forming at least one first picture parameter pertaining to a picture using the parameter set;

means for forming at least one second picture parameter using information of a slice header, the at least one second picture parameter remaining unchanged at least in all slice headers of one picture; and

means for using the at least one second picture parameter in decoding.

The bitstream according to the present invention is primarily characterized in that it comprises:

encoded pictures;

sequence parameters in a sequence parameter set;

picture parameters in a picture parameter set;

information of a slice comprising a slice header; and

6

at least one picture parameter in the slice header, the picture parameter remaining unchanged at least in all slice headers of one encoded picture.

The software program for encoding according to the present invention is primarily characterized in that the software program comprises:

defining parameters in a sequence parameter set;

defining parameters in a picture parameter set; and

defining at least one picture parameter in a slice header, the picture parameter remaining unchanged at least in all slice headers of one picture.

The software program for decoding according to the present invention is primarily characterized in that the software program comprises: the software program comprising:

recognizing a sequence parameter set and forming at least one sequence parameter pertaining to a sequence using the parameter set;

recognizing a picture parameter set and forming at least one first picture parameter pertaining to a picture using the parameter set;

forming at least one second picture parameter using information of a slice header, the at least one second picture parameter remaining unchanged at least in all slice headers of one picture; and

using the at least one second picture parameter in decoding.

The storage medium including the software program for encoding according to the present invention is primarily characterized in that the software program comprises machine executable steps for:

defining parameters in a sequence parameter set;

defining parameters in a picture parameter set; and

defining at least one picture parameter in a slice header, the picture parameter remaining unchanged at least in all slice headers of one picture.

The storage medium including the software program for decoding according to the present invention is primarily characterized in that the software program comprises machine executable steps for:

recognizing a sequence parameter set and forming at least one sequence parameter pertaining to a sequence using the parameter set;

recognizing a picture parameter set and forming at least one first picture parameter pertaining to a picture using the parameter set;

forming at least one second picture parameter using information of a slice header, the at least one second picture parameter remaining unchanged at least in all slice headers of one picture; and

using the at least one second picture parameter in decoding.

The present invention improves compression efficiency. It is likely that the number of picture parameter sets is larger than the number of sequence parameter sets and the frequency of updating picture parameter sets is higher than the frequency of updating sequence parameter sets. Thus, if there were a single parameter set structure, many sequence-level parameters that remained unchanged in the previous picture parameter set (in decoding order) should be repeated. Including picture and sequence level parameters in different syntax structures helps to avoid this problem.

The present invention clarifies the persistency rules of parameter values. Certain parameter values, such as the picture size, shall remain unchanged within the sequence. Other parameter values may change from picture to picture. If there were a single parameter set structure, there should be semantic restrictions, which parameter values must not change within a sequence even though the referred parameter set may change within the sequence. Now that the sequence param-

eter set structure is specified, it is clear that all picture parameter sets that are referred to within a sequence must refer to the same sequence parameter set. Moreover, it is clear that all slices of a picture must refer to the same picture parameter set.

DESCRIPTION OF THE DRAWINGS

FIG. 1 presents an illustration of dependencies between NAL packets and parameter set instances,

FIG. 2 depicts an advantageous embodiment of the system according to the present invention,

FIG. 3 depicts an advantageous embodiment of the encoder according to the present invention, and

FIG. 4 depicts an advantageous embodiment of the decoder according to the present invention.

DETAILED DESCRIPTION OF THE INVENTION

In an advantageous embodiment of the present invention four parameter set structures are defined: an independent GOP parameter set or a sequence parameter set, a picture parameter set, a slice parameter set, and, optionally, a presentation parameter set. Some reasons for the definition of the different parameter sets are as follows:

First, certain parameter values must remain unchanged throughout an independent GOP or within a picture. For example, the number of picture “slots” in a multi-picture buffer must not be changed during an independent GOP. Otherwise, it would be unclear how the multi-picture buffering process operates. A decoder implementation has to ensure that all the slices of a particular picture refer to the same picture parameter set. Similarly, all the slices of an independent GOP must refer to the same independent GOP parameter set. Otherwise, decoders should infer data loss or corruption. Obtaining the same functionality with one joint parameter set requires that the decoder checks that individual parameter values remain the same within a picture or within an independent GOP.

Second, a compact syntax for parameter sets is advantageous to save bits in Parameter set NAL units. Thus, it makes sense to separate independent GOP and picture parameter sets from more frequently updated slice parameter sets.

Third, display-related parameter values do not affect decoding of a coded video stream.

FIG. 1 presents an illustration of dependencies between NAL packets and parameter set instances. An arrow indicates a reference based on a parameter set identifier. The starting point of an arrow is the entity, which refers to the parameter set instance where the arrow points. The ending point of an arrow is the owner of the parameter set identifier. A slice (or a Single slice, SSP) 101, slice data partition, and IDR NAL units (IDR RP) (or independent decoder refresh NAL packets) 102 always refer to a slice parameter set 103. A slice parameter set 103 refers to a picture parameter set 104, and a picture parameter set 104 refers to both an independent GOP parameter set 105 and a presentation parameter set 106, or to a sequence parameter set. All the slices of a picture should refer to the same picture parameter set and all the slices of a sequence should refer to the same sequence parameter set.

Next, the different parameter sets according to an advantageous embodiment of the present invention will be described in more detail.

Independent GOP Parameter Set

The start of an independent GOP is identified by an Instantaneous Decoder Refresh NAL packet (IDRNP). An advantageous syntax of the packet is presented in Table 1.

TABLE 1

Independent GOP Parameter Set:	
parameter_set_id	
Profile	
Level	
Version	
log2_max_picture_number_minus_4	
number_of_reference_picture_buffers_minus_1	
required_picture_number_update_behavior	

The meaning of the fields of the packet will now be explained. The profile field defines the coding profile in use; the level field defines the level in use within the profile; the version field defines the version in use within the profile and the level. The next field, log2_max_picture_number_minus_4, specifies the MAX_PN constant used in picture number related arithmetic. MAX_PN is calculated by raising 2 to the power of the value of this field (log2_max_picture_number_minus_4) and decrementing the calculated power of 2 by 1. The field number_of_reference_picture_buffers_minus_1 defines the total number of short- and long-term picture buffers in the multi-picture buffer. If the value of the required_picture_number_update_behavior field is 1, a specific decoder behavior in case of missing picture numbers is mandated. However, this is outside the scope of the present invention wherein it is not described in this application.

Profile, level, and version are very likely to remain unchanged in an independent GOP. Therefore, they are included in the independent GOP parameter set.

A change in reference picture buffering controls, i.e., MAX_PN, number of reference picture buffers, and required picture number update behavior, would cause an undefined decoder state. A change of these parameters in the middle of an independent GOP would not bring any benefits. Hence, the number of reference picture buffers is informed in the independent GOP parameter set. A range from 0 to 15 is considered to be a practical minimum for a picture number, and therefore smaller values are should be avoided.

Picture Parameter Set

The picture parameter set includes the fields presented in Table 2.

TABLE 2

Picture Parameter Set	
parameter_set_id of a picture_parameter_set	
parameter_set_id of an independent GOP parameter set	
parameter_set_id of a presentation parameter set	
picture_width_in_MBs_minus_1	
picture_height_in_MBs_minus_1	

The first parameter_set_id field indicates the picture_parameter_set in question. The other two parameter sets indicate the independent GOP parameter set and the presentation parameter set which will be used together with the picture parameter set in encoding and decoding of the slices referring to the picture parameter set. More than one picture parameter sets can refer to the same independent GOP parameter set and/or to the same presentation parameter set. The picture_width_in_MBs_minus_1 field and the picture_height_in_MBs_minus_1 field define the size of the picture.

In some embodiments the picture_width_in_MBs_minus_1 field and picture_height_in_MBs_minus_1 field could reside in the independent GOP parameter set as well.

The presentation parameter set is referred to in picture level, as it is necessary to allow changes in the presentation parameters on picture-by-picture basis. For example, the presentation parameter set signals the display rectangle of the reconstructed pictures, which is directly related to the coded picture size signaled in the picture parameter set.

Slice Parameter Set

The slice parameter set includes the fields presented in Table 3.

TABLE 3

Slice Parameter Set	
parameter_set_id of a slice parameter set	
parameter_set_id of a picture parameter set	
entropy_coding	
motion_resolution	
constrained_intra_prediction_flag	
multiple_prediction_frames_flag	

The entropy_coding field indicates the VLC coding type of WD2. If the value of the entropy_coding field equals to zero it indicates that non-arithmetic VLC coding of WD2 is used, whereas value one indicates that arithmetic coding VLC coding of WD2 is used.

The motion_resolution field gives information on motion resolution. If the value of the motion_resolution field equals to zero a 1/4-sample motion resolution is in use, and if the value equals to one a 1/8-sample motion resolution is in use.

The constrained_intra_prediction_flag is used to provide information on prediction mode. If the constrained_intra prediction flag equals to zero normal intra prediction is used, whereas one stands for the constrained intra prediction. In the constrained intra prediction mode, no intra prediction is done from inter macroblocks.

The multiple_prediction_frames_flag gives information on reference picture usage for motion compensation. The multiple_prediction_frames_flag equal to zero signals that only the previous coded picture in coding order is used as a reference picture for motion compensation in P- and SP-frames and the most recent previous decoded and subsequent decoded pictures are used for motion compensation in B-frames. Otherwise, the reference picture(s) for prediction must be signaled for each macroblock.

The selected parameters for the slice parameter set were such that no reason to restrict their values to be unchanged in an entire independent GOP was found. Instead, it might be advantageous to allow changes in parameter values even within a picture. Examples of possible advantages include:

Use of multiple reference pictures. It may make sense to restrict the number of reference pictures to one for certain parts of the picture. For example, in wireline video conferencing equipment, the encoder may treat the center of the picture better than the edges.

Entropy coding type. It may be possible to mix multiple coded video streams to one without decoding the streams. This can be beneficial in a multi-point control unit (MCU) of a video conferencing system, for example. One endpoint may use a different entropy coding method than another one. Thus, the "mixed" stream would contain multiple entropy coding types in a same "mixed" coded picture.

Presentation Parameter Set

The presentation parameter set includes the fields presented in Table 4.

TABLE 4

Presentation Parameter Set	
parameter_set_id of a presentation parameter set	
pixel_aspect_ratio_width	
pixel_aspect_ratio_height	
display_rectangle_offset_top	
display_rectangle_offset_left	
display_rectangle_offset_bottom	
display_rectangle_offset_right	

The displayed pixel aspect ratio should be pixel_aspect_ratio_width:pixel_aspect_ratio_height. The parameter values shall be relatively prime. Value 0 is preferably forbidden. The display_rectangle_offset_top field, display_rectangle_offset_left field, display_rectangle_offset_bottom field, and display_rectangle_offset_right field define the rectangle to be displayed from the coded picture. Sample units are used.

Parameter set NAL units can be used to update values of parameter sets for a video stream. The parameter update packets can be transmitted as Network Abstraction Layer Packets (NALP). A NALP consists of a NALP header (NALPH) and a NALP payload (NALPP). The NALPH is the first byte of the NALP. The NALPH itself distinguishes different NALP types and includes one bit (EI flag) indicating the presence of errors in the NALPP following the NALPH. EI flag set to 0 means that there is no known error in the following payload whereas a 1 indicates a corrupted payload and/or a corrupted NALP type.

A Parameter set NAL unit becomes valid synchronously with the decoding process according to the specific type of the parameter set NAL unit as follows: An update of an independent GOP parameter set takes place just before the first slice of the next independent GOP (i.e., the next IDERP NAL packet) is decoded. An update of picture and presentation parameter sets takes place just before the first slice of the next picture is decoded. An update of a slice parameter set takes place substantially immediately if at least one of the contained parameters is changed. However, slice parameter set identifier used in a picture may not be redefined with different parameter values within the same coded picture.

For certain broadcast applications, such as digital TV and multicast streaming with a huge number of possible receivers, new independent GOP parameter sets, which fall out of the scope of the pre-defined ones, are likely to be updated before each independent GOP is decoded, regardless of whether or not some of the contained parameters are changed, to enable decoding in terminals that just started receiving the coded data. Other parameter sets are updated before they are referred to in the coded data.

An advantageous embodiment of a system in which the present invention can be implemented is presented in FIG. 2. The pictures to be encoded can be, for example, pictures of a video stream from a video source 3, e.g. a camera, a video recorder, etc. The pictures (frames) of the video stream can be divided into smaller portions such as slices. The slices can further be divided into macroblocks and blocks. The encoder 1 selects proper parameter sets for use with the encoding process and sends the selected parameter sets to the decoder 2. The decoder stores the parameter sets to memory 2.3 (FIG. 4). If the decoder already has a correct parameter set, it is not necessary to transmit such parameter set to the decoder 2 but only an indication of the correct parameter set.

In the encoder 1 the video stream is encoded to reduce the information to be transmitted via a transmission channel 4, or to a storage media (not shown). Pictures of the video stream

11

are input to the encoder 1. The encoder has an encoding buffer 1.1 (FIG. 3) for temporarily storing some of the pictures to be encoded. The encoder 1 also includes a memory 1.3 and a processor 1.2 in which the encoding tasks according to the invention can be applied. The memory 1.3 and the processor 1.2 can be common with the transmitting device 6 or the transmitting device 6 can have another processor and/or memory (not shown) for other functions of the transmitting device 6. The encoder 1 performs motion estimation and/or some other tasks to compress the video stream. In motion estimation similarities between the picture to be encoded (the current picture) and a previous and/or latter picture are searched. If similarities are found the compared picture or part of it can be used as a reference picture for the picture to be encoded. In the JVT coding standard the display order and the decoding order of the pictures are not necessarily the same, wherein the reference picture has to be stored in a buffer (e.g. in the encoding buffer 1.1) as long as it is used as a reference picture. The encoder 1 may also insert information on display order of the pictures into the bitstream.

From the encoding process the encoded pictures are moved to an encoded picture buffer 5.2, if necessary. The encoded pictures are transmitted from the encoder 1 to the decoder 2 via the transmission channel 4. In the decoder 2 the encoded pictures are decoded to form uncompressed pictures corresponding as much as possible to the encoded pictures. Each decoded picture is buffered in the DPB 2.1 of the decoder 2 unless it is displayed substantially immediately after the decoding and is not used as a reference picture. Preferably both the reference picture buffering and the display picture buffering are combined and they use the same decoded picture buffer 2.1. This eliminates the need for storing the same pictures in two different places thus reducing the memory requirements of the decoder 2.

The decoder 2 also includes a memory 2.3 and a processor 2.2 in which the decoding tasks according to the invention can be applied. The memory 2.3 and the processor 2.2 can be common with the receiving device 8 or the receiving device 8 can have another processor and/or memory (not shown) for other functions of the receiving device 8.

It is obvious that the present invention is not limited solely to the above described embodiments but it can be modified within the scope of the appended claims.

The invention claimed is:

1. A method for encoding sequences of pictures into a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, the method comprising:

defining, in an encoder, parameter values in a sequence parameter set for a sequence of pictures;
defining, in the encoder, parameter values in a picture parameter set for a picture; and
defining, in the encoder, at least one picture parameter value in a slice header, the picture parameter value remaining unchanged at least in all slice headers of one picture.

2. The method according to claim 1, wherein the slice header is included with a reference to a picture parameter set.

3. The method according to claim 1, wherein the picture parameter set is included with a reference to a sequence parameter set.

4. The method according to claim 1, wherein the picture parameter value is selected from a group of information of a picture order count and a frame number.

5. The method according to claim 1, wherein the sequence parameter set and picture parameter set are transmitted less often than once per each picture.

12

6. A method for decoding sequences of pictures from a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, the method comprising:

recognizing, in a decoder, a sequence parameter set and forming at least one sequence parameter pertaining to a sequence using the parameter set;

recognizing, in the decoder, a picture parameter set and forming at least one first picture parameter value pertaining to a picture using the parameter set;

forming, in the decoder, at least one second picture parameter value using information of a slice header, the at least one second picture parameter value remaining unchanged at least in all slice headers of one picture; and
using, in the decoder, the at least one second picture parameter value in decoding.

7. The method according to claim 6, wherein the slice header is included with a reference to a picture parameter set.

8. The method according to claim 6, wherein the picture parameter set is included with a reference to a sequence parameter set.

9. The method according to claim 6, wherein the second picture parameter value is selected from a group of information of a picture order count and a frame number.

10. An encoder for encoding sequences of pictures into a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, the encoder comprising:

a processor configured for:

defining parameter values in a sequence parameter set for a sequence of pictures;

defining parameter values in a picture parameter set for a picture; and

defining at least one picture parameter value in a slice header, the picture parameter value remaining unchanged at least in all slice headers of one picture.

11. A decoder for decoding sequences of pictures from a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, the decoder comprising:

a processor configured for:

recognizing a sequence parameter set for a sequence of pictures and forming at least one sequence parameter pertaining to a sequence using the parameter set for a picture;

recognizing a picture parameter set and forming at least one first picture parameter value pertaining to a picture using the parameter set;

forming at least one second picture parameter value using information of a slice header, the at least one second picture parameter value remaining unchanged at least in all slice headers of one picture; and

using the at least one second picture parameter value in decoding.

12. A system comprising an encoder for encoding sequences of pictures into a bitstream, a decoder for decoding sequences of pictures from the bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, the encoder comprising:

a processor configured for:

defining parameter values in a sequence parameter set for a sequence of pictures;

defining parameter values in a picture parameter set for a picture; and

defining at least one picture parameter value in a slice header, the picture parameter value remaining unchanged at least in all slice headers of one picture;

13

and the decoder comprising:

a processor configured for:

recognizing a sequence parameter set for a sequence of pictures and forming at least one sequence parameter pertaining to a sequence using the parameter set;

recognizing a picture parameter set for a picture and forming at least one first picture parameter value pertaining to a picture using the parameter set;

forming at least one second picture parameter value using information of a slice header, the at least one second picture parameter value remaining unchanged at least in all slice headers of one picture; and

using the at least one second picture parameter value in decoding.

13. The system according to claim 12, wherein a parameter set is stored in both the encoder and the decoder.

14. A transmitting device comprising an encoder for encoding sequences of pictures into a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, the encoder comprising:

a processor configured for:

defining parameter values in a sequence parameter set for a sequence of pictures;

defining parameter values in a picture parameter set for a picture; and

defining at least one picture parameter value in a slice header, the picture parameter value remaining unchanged at least in all slice headers of one picture.

15. A receiving device comprising a decoder for decoding sequences of pictures from a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, the decoder comprising:

a processor configured for:

recognizing a sequence parameter set for a sequence of pictures and forming at least one sequence parameter pertaining to a sequence using the parameter set;

recognizing a picture parameter set for a picture and forming at least one first picture parameter value pertaining to a picture using the parameter set;

forming at least one second picture parameter value using information of a slice header, the at least one second picture parameter value remaining unchanged at least in all slice headers of one picture; and

using the at least one second picture parameter value in decoding.

16. A bitstream comprising:

encoded pictures;

sequence parameters in a sequence parameter set for a sequence of pictures;

picture parameter values in a picture parameter set for a picture;

information of a slice comprising a slice header; and

at least one picture parameter value in the slice header, the picture parameter value remaining unchanged at least in all slice headers of one encoded picture.

17. The bitstream according to claim 16, wherein the slice header is included with a reference to a picture parameter set.

18. The bitstream according to claim 16, wherein the picture parameter set is included with a reference to a sequence parameter set.

19. The bitstream according to claim 16, wherein the picture parameter value is selected from a group of information of a picture order count and a frame number.

14

20. A computer readable storage medium embedded with a computer program comprising programming code for execution on a processor, the programming code for encoding sequences of pictures into a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, and the programming code for:

defining parameter values in a sequence parameter set for a sequence of pictures;

defining parameter values in a picture parameter set for a picture; and

defining at least one picture parameter value in a slice header, the picture parameter value remaining unchanged at least in all slice headers of one picture.

21. A computer readable storage medium embedded with a computer program comprising programming code for execution on a processor, the programming code for decoding sequences of pictures from a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, and the programming code for:

recognizing a sequence parameter set for a sequence of pictures and forming at least one sequence parameter pertaining to a sequence using the parameter set;

recognizing a picture parameter set for a picture and forming at least one first picture parameter value pertaining to a picture using the parameter set;

forming at least one second picture parameter value using information of a slice header, the at least one second picture parameter value remaining unchanged at least in all slice headers of one picture; and

using the at least one second picture parameter value in decoding.

22. An encoder for encoding sequences of pictures into a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, the encoder comprising:

means for defining parameter values in a sequence parameter set for a sequence of pictures;

means for defining parameter values in a picture parameter set for a picture; and

means for defining at least one picture parameter value in a slice header, the picture parameter value remaining unchanged at least in all slice headers of one picture.

23. A decoder for decoding sequences of pictures from a bitstream, wherein parameters are defined in a parameter set and each picture comprises information of one or more slices, the decoder comprising:

means for recognizing a sequence parameter set for a sequence of pictures and forming at least one sequence parameter pertaining to a sequence using the parameter set for a picture;

means for recognizing a picture parameter set and forming at least one first picture parameter value pertaining to a picture using the parameter set;

means for forming at least one second picture parameter value using information of a slice header, the at least one second picture parameter value remaining unchanged at least in all slice headers of one picture; and

means for using the at least one second picture parameter value in decoding.

A method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the method comprising:

a) when values for sub-pixels at half unit horizontal and unit vertical locations, and unit horizontal and half unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) when values for sub-pixels at half unit horizontal and half unit vertical locations are required, interpolating such values directly using a weighted sum of values for sub-pixels residing at half unit horizontal and unit vertical locations calculated according to step (a); and

c) when values for sub-pixels at quarter unit horizontal and quarter unit vertical locations are required, interpolating such values by taking the average of at least one pair of a first pair of values of a sub-pixel located at a half unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and half unit vertical location and a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a half unit horizontal and half unit vertical location.

METHOD FOR SUB-PIXEL VALUE INTERPOLATION

The present invention relates to a method for sub-pixel value interpolation in the encoding and decoding of data. It relates particularly, but not exclusively, to encoding and decoding of digital video.

BACKGROUND OF THE INVENTION

Digital video sequences, like ordinary motion pictures recorded on film, comprise a sequence of still images, the illusion of motion being created by displaying the images one after the other at a relatively fast frame rate, typically 15 to 30 frames per second. Because of the relatively fast frame rate, images in consecutive frames tend to be quite similar and thus contain a considerable amount of redundant information. For example, a typical scene may comprise some stationary elements, such as background scenery, and some moving areas, which may take many different forms, for example the face of a newsreader, moving traffic and so on. Alternatively, the camera recording the scene may itself be moving, in which case all elements of the image have the same kind of motion. In many cases, this means that the overall change between one video frame and the next is rather small. Of course, this depends on the nature of the movement. For example, the faster the movement, the greater the change from one frame to the next. Similarly, if a scene contains a number of moving elements, the change from one frame to the next is likely to be greater than in a scene where only one element is moving.

It should be appreciated that each frame of a raw, that is uncompressed, digital video sequence comprises a very large amount of image information. Each frame of an uncompressed digital video sequence is formed from an array of image pixels. For example, in a commonly used digital video format, known as the Quarter Common Interchange Format (QCIF), a frame comprises an array of 176x144 pixels, in which case each frame has 25,344 pixels. In turn, each pixel is represented by a certain number of bits, which carry information about the luminance and/or colour content of the region of the image corresponding to the pixel. Commonly, a so-called YUV colour model is used to represent the luminance and chrominance content of the image. The luminance, or Y, component represents the intensity (brightness) of the image, while the colour content of the image is represented by two chrominance components, labelled U and V.

Colour models based on a luminance/chrominance representation of image content provide certain advantages compared with colour models that are based on a representation involving primary colours (that is Red, Green and Blue, RGB). The human visual system is more sensitive to intensity variations than it is to colour variations; YUV colour models exploit this property by using a lower spatial resolution for the chrominance components (U, V) than for the luminance component (Y). In this way the amount of information needed to code the colour information in an image can be reduced with an acceptable reduction in image quality.

The lower spatial resolution of the chrominance components is usually attained by sub-sampling. Typically, a block of 16x16 image pixels is represented by one block of 16x16 pixels comprising luminance information and the corresponding chrominance components are each represented by one block of 8x8 pixels representing an area of the image equivalent to that of the 16x16 pixels of the luminance

2

component. The chrominance components are thus spatially sub-sampled by a factor of 2 in the x and y directions. The resulting assembly of one 16x16 pixel luminance block and two 8x8 pixel chrominance blocks is commonly referred to as a YUV macroblock, or macroblock, for short.

A QCIF image comprises 11x9 macroblocks. If the luminance blocks and chrominance blocks are represented with 8 bit resolution (that is by numbers in the range 0 to 255), the total number of bits required per macroblock is $(16 \times 16 \times 8) + 2 \times (8 \times 8 \times 8) = 3072$ bits. The number of bits needed to represent a video frame in QCIF format is thus $99 \times 3072 = 304,128$ bits. This means that the amount of data required to transmit/record/display a video sequence in QCIF format, represented using a YUV colour model, at a rate of 30 frames per second, is more than 9 Mbps (million bits per second). This is an extremely high data rate and is impractical for use in video recording, transmission and display applications because of the very large storage capacity, transmission channel capacity and hardware performance required.

If video data is to be transmitted in real-time over a fixed line network such as an ISDN (Integrated Services Digital Network) or a conventional PSTN (Public Service Telephone Network), the available data transmission bandwidth is typically of the order of 64 kbits/s. In mobile videotelephony, where transmission takes place at least in part over a radio communications link, the available bandwidth can be as low as 20 kbits/s. This means that a significant reduction in the amount of information used to represent video data must be achieved in order to enable transmission of digital video sequences over low bandwidth communication networks. For this reason video compression techniques have been developed which reduce the amount of information transmitted while retaining an acceptable image quality.

Video compression methods are based on reducing the redundant and perceptually irrelevant parts of video sequences. The redundancy in video sequences can be categorised into spatial, temporal and spectral redundancy. 'Spatial redundancy' is the term used to describe the correlation between neighbouring pixels within a frame. The term 'temporal redundancy' expresses the fact that the objects appearing in one frame of a sequence are likely to appear in subsequent frames, while 'spectral redundancy' refers to the correlation between different colour components of the same image.

Sufficiently efficient compression cannot usually be achieved by simply reducing the various forms of redundancy in a given sequence of images. Thus, most current video encoders also reduce the quality of those parts of the video sequence which are subjectively the least important. In addition, the redundancy of the compressed video bit-stream is itself reduced by means of efficient loss-less encoding. Typically, this is achieved using a technique known as 'variable length coding' (VLC).

Modern video compression standards, such as ITU-T recommendations H.261, H.263(+)(++), H.26L and the Motion Picture Experts Group recommendation MPEG-4 make use of 'motion compensated temporal prediction'. This is a form of temporal redundancy reduction in which the content of some (often many) frames in a video sequence is 'predicted' from other frames in the sequence by tracing the motion of objects or regions of an image between frames.

Compressed images which do not make use of temporal redundancy reduction are usually called INTRA-coded or

I-frames, whereas temporally predicted images are called INTER-coded or P-frames. In the case of INTER frames, the predicted (motion-compensated) image is rarely precise enough to represent the image content with sufficient quality, and therefore a spatially compressed prediction error (PE) frame is also associated with each INTER frame. Many video compression schemes can also make use of bi-directionally predicted frames, which are commonly referred to as B-pictures or B-frames. B-pictures are inserted between reference or so-called 'anchor' picture pairs (I or P frames) and are predicted from either one or both of the anchor pictures. B-pictures are not themselves used as anchor pictures, that is no other frames are predicted from them, and therefore, they can be discarded from the video sequence without causing deterioration in the quality of future pictures.

The different types of frame that occur in a typical compressed video sequence are illustrated in FIG. 3 of the accompanying drawings. As can be seen from the figure, the sequence starts with an INTRA or I frame 30. In FIG. 3, arrows 33 denote the 'forward' prediction process by which P-frames (labelled 34) are formed. The bidirectional prediction process by which B-frames (36) are formed is denoted by arrows 31a and 31b, respectively.

A schematic diagram of an example video coding system using motion compensated prediction is shown in FIGS. 1 and 2. FIG. 1 illustrates an encoder 10 employing motion compensation and FIG. 2 illustrates a corresponding decoder 20. The encoder 10 shown in FIG. 1 comprises a Motion Field Estimation block 11, a Motion Field Coding block 12, a Motion Compensated Prediction block 13, a Prediction Error Coding block 14, a Prediction Error Decoding block 15, a Multiplexing block 16, a Frame Memory 17, and an adder 19. The decoder 20 comprises a Motion Compensated Prediction block 21, a Prediction Error Decoding block 22, a Demultiplexing block 23 and a Frame Memory 24.

The operating principle of video coders using motion compensation is to minimise the amount of information in a prediction error frame $E_n(x,y)$, which is the difference between a current frame $I_n(x,y)$ being coded and a prediction frame $P_n(x,y)$. The prediction error frame is thus:

$$E_n(x,y) = I_n(x,y) - P_n(x,y). \quad (1)$$

The prediction frame $P_n(x,y)$ is built using pixel values of a reference frame $R_n(x,y)$, which is generally one of the previously coded and transmitted frames, for example the frame immediately preceding the current frame and is available from the Frame Memory 17 of the encoder 10. More specifically, the prediction frame $P_n(x,y)$ is constructed by finding so-called 'prediction pixels' in the reference frame $R_n(x,y)$ which correspond substantially with pixels in the current frame. Motion information, describing the relationship (e.g. relative location, rotation, scale etc.) between pixels in the current frame and their corresponding prediction pixels in the reference frame is derived and the prediction frame is constructed by moving the prediction pixels according to the motion information. In this way, the prediction frame is constructed as an approximate representation of the current frame, using pixel values in the reference frame. The prediction error frame referred to above therefore represents the difference between the approximate representation of the current frame provided by the prediction frame and the current frame itself. The basic advantage provided by video encoders that use motion compensated prediction arises from the fact that a comparatively compact description of the current frame can be obtained by representing it

in terms of the motion information required to form its prediction together with the associated prediction error information in the prediction error frame.

However, due to the very large number of pixels in a frame, it is generally not efficient to transmit separate motion information for each pixel to the decoder. Instead, in most video coding schemes, the current frame is divided into larger image segments S_k and motion information relating to the segments is transmitted to the decoder. For example, motion information is typically provided for each macroblock of a frame and the same motion information is then used for all pixels within the macroblock. In some video coding standards, such as H.26L, a macroblock can be divided into smaller blocks, each smaller block being provided with its own motion information.

The motion information usually takes the form of motion vectors $[\Delta x(x,y), \Delta y(x,y)]$. The pair of numbers $\Delta x(x,y)$ and $\Delta y(x,y)$ represents the horizontal and vertical displacements of a pixel at location (x,y) in the current frame $I_n(x,y)$ with respect to a pixel in the reference frame $R_n(x,y)$. The motion vectors $[\Delta x(x,y), \Delta y(x,y)]$ are calculated in the Motion Field Estimation block 11 and the set of motion vectors of the current frame $[\Delta x(\bullet), \Delta y(\bullet)]$ is referred to as the motion vector field.

Typically, the location of a macroblock in a current video frame is specified by the (x,y) co-ordinate of its upper left-hand corner. Thus, in a video coding scheme in which motion information is associated with each macroblock of a frame, each motion vector describes the horizontal and vertical displacement $\Delta x(x,y)$ and $\Delta y(x,y)$ of a pixel representing the upper left-hand corner of a macroblock in the current frame $I_n(x,y)$ with respect to a pixel in the upper left-hand corner of a substantially corresponding block of prediction pixels in the reference frame $R_n(x,y)$ (as shown in FIG. 4b).

Motion estimation is a computationally intensive task. Given a reference frame $R_n(x,y)$ and, for example, a square macroblock comprising $N \times N$ pixels in a current frame (as shown in FIG. 4a), the objective of motion estimation is to find an $N \times N$ pixel block in the reference frame that matches the characteristics of the macroblock in the current picture according to some criterion. This criterion can be, for example, a sum of absolute differences (SAD) between the pixels of the macroblock in the current frame and the block of pixels in the reference frame with which it is compared. This process is known generally as 'block matching'. It should be noted that, in general, the geometry of the block to be matched and that in the reference frame do not have to be the same, as real-world objects can undergo scale changes, as well as rotation and warping. However, in current international video coding standards, only a translational motion model is used (see below) and thus fixed rectangular geometry is sufficient.

Ideally, in order to achieve the best chance of finding a match, the whole of the reference frame should be searched. However, this is impractical as it imposes too high a computational burden on the video encoder. Instead, the search region is restricted to region $[-p,p]$ around the original location of the macroblock in the current frame, as shown in FIG. 4c.

In order to reduce the amount of motion information to be transmitted from the encoder 10 to the decoder 20, the motion vector field is coded in the Motion Field Coding block 12 of the encoder 10, by representing it with a motion model. In this process, the motion vectors of image segments are re-expressed using certain predetermined functions or, in other words, the motion vector field is repre-

5

sented with a model. Almost all currently used motion vector field models are additive motion models, complying with the following general formula:

$$\Delta x(x, y) = \sum_{i=0}^{N-1} a_i f_i(x, y) \quad (2)$$

$$\Delta y(x, y) = \sum_{i=0}^{M-1} b_i g_i(x, y) \quad (3)$$

where coefficients a_i and b_i are called motion coefficients. The motion coefficients are transmitted to the decoder **20** (information stream **2** in FIGS. 1 and 2). Functions f_i and g_i are called motion field basis functions, and are known both to the encoder and decoder. An approximate motion vector field ($\Delta x(x, y), \Delta y(x, y)$) can be constructed using the coefficients and the basis functions. As the basis functions are known to (that is stored in) both the encoder **10** and the decoder **20**, only the motion coefficients need to be transmitted to the encoder, thus reducing the amount of information required to represent the motion information of the frame.

The simplest motion model is the translational motion model which requires only two coefficients to describe the motion vectors of each segment. The values of motion vectors are given by:

$$\begin{aligned} \Delta x(x, y) &= a_0 \\ \Delta y(x, y) &= b_0 \end{aligned} \quad (4)$$

This model is widely used in various international standards (ISO MPEG-1, MPEG-2, MPEG-4, ITU-T Recommendations H.261 and H.263) to describe the motion of 16×16 and 8×8 pixel blocks. Systems which use a translational motion model typically perform motion estimation at full pixel resolution or some integer fraction of full pixel resolution, for example at half or one quarter pixel resolution.

The prediction frame $P_n(x, y)$ is constructed in the Motion Compensated Prediction block **13** in the encoder **10**, and is given by:

$$P_n(x, y) = R_n[x + \tilde{\Delta}x(x, y), y + \tilde{\Delta}y(x, y)] \quad (5)$$

In the Prediction Error Coding block **14**, the prediction error frame $E_n(x, y)$ is typically compressed by representing it as a finite series (transform) of some 2-dimensional functions. For example, a 2-dimensional Discrete Cosine Transform (DCT) can be used. The transform coefficients are quantised and entropy (for example Huffman) coded before they are transmitted to the decoder (information stream **1** in FIGS. 1 and 2). Because of the error introduced by quantisation, this operation usually produces some degradation (loss of information) in the prediction error frame $E_n(x, y)$. To compensate for this degradation, the encoder **10** also comprises a Prediction Error Decoding block **15**, where a decoded prediction error frame $\tilde{E}_n(x, y)$ is constructed using the transform coefficients. This locally decoded prediction error frame is added to the prediction frame $P_n(x, y)$ in the adder **19** and the resulting decoded current frame $\tilde{I}_n(x, y)$ is stored in the Frame Memory **17** for further use as the next reference frame $R_{n+1}(x, y)$.

The information stream **2** carrying information about the motion vectors is combined with information about the prediction error in multiplexer **16** and an information stream **3** containing typically at least those two types of information is sent to the decoder **20**.

6

The operation of a corresponding video decoder **20** will now be described.

The Frame Memory **24** of the decoder **20** stores a previously reconstructed reference frame $R_n(x, y)$. The prediction frame $P_n(x, y)$ is constructed in the Motion Compensated Prediction block **21** of the decoder **20** according to equation 5, using received motion coefficient information and pixel values of the previously reconstructed reference frame $R_n(x, y)$. The transmitted transform coefficients of the prediction error frame $E_n(x, y)$ are used in the Prediction Error Decoding block **22** to construct the decoded prediction error frame $\tilde{E}_n(x, y)$. The pixels of the decoded current frame $\tilde{I}_n(x, y)$ are then reconstructed by adding the prediction frame $P_n(x, y)$ and the decoded prediction error frame $\tilde{E}_n(x, y)$:

$$\tilde{I}_n(x, y) = P_n(x, y) + \tilde{E}_n(x, y) = R_n[x + \tilde{\Delta}x(x, y), y + \tilde{\Delta}y(x, y)] + \tilde{E}_n(x, y). \quad (6)$$

This decoded current frame may be stored in the Frame Memory **24** as the next reference frame $R_{n+1}(x, y)$.

In the description of motion compensated encoding and decoding of digital video presented above, the motion vector $[\Delta x(x, y), \Delta y(x, y)]$ describing the motion of a macroblock in the current frame with respect to the reference frame $R_n(x, y)$ can point to any of the pixels in the reference frame. This means that motion between frames of a digital video sequence can only be represented at a resolution which is determined by the image pixels in the frame (so-called full pixel resolution). Real motion, however, has arbitrary precision, and thus the system described above can only provide approximate modelling of the motion between successive frames of a digital video sequence. Typically, modelling of motion between video frames with full pixel resolution is not sufficiently accurate to allow efficient minimisation of the prediction error (PE) information associated with each macroblock/frame. Therefore, to enable more accurate modelling of real motion and to help reduce the amount of PE information that must be transmitted from encoder to decoder, many video coding standards, such as H.263(++) and H.26L, allow motion vectors to point 'in between' image pixels. In other words, the motion vectors can have 'sub-pixel' resolution. Allowing motion vectors to have sub-pixel resolution adds to the complexity of the encoding and decoding operations that must be performed, so it is still advantageous to limit the degree of spatial resolution a motion vector may have. Thus, video coding standards, such as those previously mentioned, typically only allow motion vectors to have full-, half- or quarter-pixel resolution.

Motion estimation with sub-pixel resolution is usually performed as a two-stage process, as illustrated in FIG. 5, for a video coding scheme which allows motion vectors to have full- or half-pixel resolution. In the first step, a motion vector having full-pixel resolution is determined using any appropriate motion estimation scheme, such as the block-matching process described in the foregoing. The resulting motion vector, having full-pixel resolution is shown in FIG. 5.

In the second stage, the motion vector determined in the first stage is refined to obtain the desired half-pixel resolution. In the example illustrated in FIG. 5, this is done by forming eight new search blocks of 16×16 pixels, the location of the top-left corner of each block being marked with an X in FIG. 5. These locations are denoted as $[\Delta x + m/2, \Delta y + n/2]$, where m and n can take the values -1, 0 and +1, but cannot be zero at the same time. As only the pixel values of original image pixels are known, the values (for example luminance and/or chrominance values) of the

sub-pixels residing at half-pixel locations must be estimated for each of the eight new search blocks, using some form of interpolation scheme.

Having interpolated the values of the sub-pixels at half-pixel resolution, each of the eight search blocks is compared with the macroblock whose motion vector is being sought. As in the block matching process performed in order to determine the motion vector with full pixel resolution, the macroblock is compared with each of the eight search blocks according to some criterion, for example a SAD. As a result of the comparisons, a minimum SAD value will generally be obtained. Depending on the nature of the motion in the video sequence, this minimum value may correspond to the location specified by the original motion vector (having full-pixel resolution), or it may correspond to a location having a half-pixel resolution. Thus, it is possible to determine whether a motion vector should point to a full-pixel or sub-pixel location and if sub-pixel resolution is appropriate, to determine the correct sub-pixel resolution motion vector. It should also be appreciated that the scheme just described can be extended to other sub-pixel resolutions (for example, one-quarter-pixel resolution) in an entirely analogous fashion.

In practice, the estimation of a sub-pixel value in the reference frame is performed by interpolating the value of the sub-pixel from surrounding pixel values. In general, interpolation of a sub-pixel value $F(x,y)$ situated at a non-integer location $(x, y)=(n+\Delta x, m+\Delta y)$, can be formulated as a two-dimensional operation, represented mathematically as:

$$F(x, y) = \sum_{k=-K}^{K-1} \sum_{l=-L}^{L-1} f(k+K, l+L) F(n+k, m+l) \quad (7)$$

where $f(k,l)$ are filter coefficients and n and m are obtained by truncating x and y , respectively, to integer values. Typically, the filter coefficients are dependent on the x and y values and the interpolation filters are usually so-called 'separable filters', in which case sub-pixel value $F(x,y)$ can be calculated as follows:

$$F(x, y) = \sum_{k=-K}^{K-1} f(k+K) \sum_{l=-K}^{K-1} f(l+K) F(n+k, m+l) \quad (8)$$

The motion vectors are calculated in the encoder. Once the corresponding motion coefficients are transmitted to the decoder, it is a straightforward matter to interpolate the required sub-pixels using an interpolation method identical to that used in the encoder. In this way, a frame following a reference frame in the Frame Memory 24, can be reconstructed from the reference frame and the motion vectors.

The simplest way of applying sub-pixel value interpolation in a video coder is to interpolate each sub-pixel value every time it is needed. However, this is not an efficient solution in a video encoder, because it is likely that the same sub-pixel value will be required several times and thus calculations to interpolate the same sub-pixel value will be performed multiple times. This results in an unnecessary increase of computational complexity/burden in the encoder.

An alternative approach, which limits the complexity of the encoder, is to pre-calculate and store all sub-pixel values in a memory associated with the encoder. This solution is called interpolation 'before-hand' interpolation hereafter in this document. While limiting complexity, before-hand

interpolation has the disadvantage of increasing memory usage by a large margin. For example, if the motion vector accuracy is one quarter pixel in both horizontal and vertical dimensions, storing pre-calculated sub-pixel values for a complete image results in a memory usage that is 16 times that required to store the original, non-interpolated image. In addition, it involves the calculation of some sub-pixels which might not actually be required in calculating motion vectors in the encoder. Before-hand interpolation is also particularly inefficient in a video decoder, as the majority of pre-calculated sub-pixel values will never be required by the decoder. Thus, it is advantageous not to use pre-calculation in the decoder.

So-called 'on-demand' interpolation can be used to reduce memory requirements in the encoder. For example, if the desired pixel precision is quarter pixel resolution, only sub-pixels at one half unit resolution are interpolated before-hand for the whole frame and stored in the memory. Values of one-quarter pixel resolution sub-pixels are only calculated during the motion estimation/compensation process as and when it is required. In this case memory usage is only 4 times that required to store the original, non-interpolated image.

It should be noted that when before-hand interpolation is used, the interpolation process constitutes only a small fraction of the total encoder computational complexity/burden, since every pixel is interpolated just once. Therefore, in the encoder, the complexity of the interpolation process itself is not very critical when before-hand sub-pixel value interpolation is used. On the other hand, on-demand interpolation poses a much higher computational burden on the encoder, since sub-pixels may be interpolated many times. Hence the complexity of interpolation process, which may be considered in terms of the number of computational operations or operational cycles that must be performed in order to interpolate the sub-pixel values, becomes an important consideration.

In the decoder, the same sub-pixel values are used a few times at most and some are not needed at all. Therefore, in the decoder it is advantageous not to use before-hand interpolation at all, that is, it is advantageous not to pre-calculate any sub-pixel values.

Two interpolation schemes have been developed as part of the work ongoing in the ITU-Telecommunications Standardization Sector, Study Group 16, Video Coding Experts Group (VCEG), Questions 6 and 15. These approaches were proposed for incorporation into ITU-T recommendation H.26L and have been implemented in test models (TML) for the purposes of evaluation and further development. The test model corresponding to Question 15 is referred to as Test Model 5 (TML5), while that resulting from Question 6 is known as Test Model 6 (TML6). The interpolation schemes proposed in both TML5 and TML6 will now be described.

Throughout the description of the sub-pixel value interpolation scheme used in test model TML5, reference will be made to FIG. 12a, which defines a notation for describing pixel and sub-pixel locations specific to TML5. A separate notation, defined in FIG. 13a, will be used in the discussion of the sub-pixel value interpolation scheme used in TML6. A still further notation, illustrated in FIG. 14a, will be used later in the text in connection with the sub-pixel value interpolation method according to the invention. It should be appreciated that the three different notations used in the text are intended to assist in the understanding of each interpolation method and to help distinguish differences between them. However, in all three figures, the letter A is used to denote original image pixels (full pixel resolution). More

specifically, the letter A represents the location of pixels in the image data representing a frame of a video sequence, the pixel values of pixels A being either received as current frame $I_n(x,y)$ from a video source, or reconstructed and stored as a reference frame $R_n(x,y)$ in the Frame Memory 17, 24 of the encoder 10 or the decoder 20. All other letters represent sub-pixel locations, the values of the sub-pixels situated at the sub-pixel locations being obtained by interpolation.

Certain other terms will also be used in a consistent manner throughout the text to identify particular pixel and sub-pixel locations. These are as follows:

The term 'unit horizontal location' is used to describe the location of any sub-pixel that is constructed in a column of the original image data. Sub-pixels c and e in FIGS. 12a and 13a, as well as sub-pixels b and e in FIG. 14a have unit horizontal locations.

The term 'unit vertical location' is used to describe any sub-pixel that is constructed in a row of the original image data. Sub-pixels b and d in FIGS. 12a and 13a as well as sub-pixels b and d in FIG. 14a have unit vertical locations.

By definition, pixels A have unit horizontal and unit vertical locations.

The term 'half horizontal location' is used to describe the location of any sub-pixel that is constructed in a column that lies at half pixel resolution. Sub-pixels b, c, and e shown in FIGS. 12a and 13a fall into this category, as do sub-pixels b, c and f in FIG. 14a. In a similar manner, the term 'half vertical location' is used to describe the location of any sub-pixel that is constructed in a row that lies at half-pixel resolution, such as sub-pixels c and d in FIGS. 12a and 13a, as well as sub-pixels b, c and g in FIG. 14a.

Furthermore, the term 'quarter horizontal location' refers to any sub-pixel that is constructed in a column which lies at quarter-pixel resolution, such as sub-pixels d and e in FIG. 12a, sub-pixels d and g in FIG. 13a and sub-pixels d, g and h in FIG. 14a. Analogously, the term 'quarter vertical location' refers to sub-pixels that are constructed in a row which lies at quarter-pixel resolution. In FIG. 12a, sub-pixels e and f fall into this category, as do sub-pixels e, f and g in FIG. 13a and sub-pixels e, f and h in FIG. 14a.

The definition of each of the terms described above is shown by 'envelopes' drawn on the corresponding figures.

It should further be noted that it is often convenient to denote a particular pixel with a two-dimensional reference. In this case, the appropriate two-dimensional reference can be obtained by examining the intersection of the envelopes in FIGS. 12a, 13a and 14a. Applying this principle, pixel d in FIG. 12a, for example, has a half horizontal and half vertical location and sub-pixel e has a unit horizontal and quarter vertical location. In addition, and for ease of reference, sub-pixels that reside at half unit horizontal and unit vertical locations, unit horizontal and half unit vertical locations as well as half unit horizontal and half unit vertical locations, will be referred to as $\frac{1}{2}$ resolution sub-pixels. Sub-pixels which reside at any quarter unit horizontal and/or quarter unit vertical location will be referred to as $\frac{1}{4}$ resolution sub-pixels.

It should also be noted that in the descriptions of the two test models and in the detailed description of the invention itself, it will be assumed that pixels have a minimum value of 0 and a maximum value of 2^n-1 where n is the number of bits reserved for a pixel value. The number of bits is typically 8. After a sub-pixel has been interpolated, if the value of that interpolated sub-pixel exceeds the value of 2^n-1 , it is restricted to the range of $[0, 2^n-1]$, i.e. values lower than the minimum allowed value will become the

minimum value (0) and values larger than the maximum will become maximum value (2^n-1). This operation is called clipping.

The sub-pixel value interpolation scheme according to TML5 will now be described in detail with reference to FIGS. 12a, 12b and 12c.

1. The value for the sub-pixel at half unit horizontal and unit vertical location, that is $\frac{1}{2}$ resolution sub-pixel b in FIG. 12a, is calculated using a 6-tap filter. The filter interpolates a value for $\frac{1}{2}$ resolution sub-pixel b based upon the values of the 6 pixels (A_1 to A_6) situated in a row at unit horizontal locations and unit vertical locations symmetrically about b, as shown in FIG. 12b, according to the formula $b=(A_1-5A_2+20A_3+20A_4-5A_5+A_6+16)/32$. The operator / denotes division with truncation. The result is clipped to lie in the range $[0, 2^n-1]$.

2. Values for the $\frac{1}{2}$ resolution sub-pixels labelled c are calculated using the same six tap filter as used in step 1 and the six nearest pixels or sub-pixels (A or b) in the vertical direction. Referring now to FIG. 12c, the filter interpolates a value for the $\frac{1}{2}$ resolution sub-pixel c located at unit horizontal and half vertical location based upon the values of the 6 pixels (A_1 to A_6) situated in a column at unit horizontal locations and unit vertical locations symmetrically about c, according to the formula $c=(A_1-5A_2+20A_3+20A_4-5A_5+A_6+16)/32$. Similarly, a value for the $\frac{1}{2}$ resolution sub-pixel c at half horizontal and half vertical location is calculated according to $c=(b_1-5b_2+20b_3+20b_4-5b_5+b_6+16)/32$. Again, the operator / denotes division with truncation. The values calculated for the c sub-pixels are further clipped to lie in the range $[0, 2^n-1]$.

At this point in the interpolation process the values of all $\frac{1}{2}$ resolution sub-pixels have been calculated and the process proceeds to the calculation of $\frac{1}{4}$ resolution sub-pixel values.

3. Values for the $\frac{1}{4}$ resolution sub-pixels labelled d are calculated using linear interpolation and the values of the nearest pixels and/or $\frac{1}{2}$ resolution sub-pixels in the horizontal direction. More specifically, values for $\frac{1}{4}$ resolution sub-pixels d located at quarter horizontal and unit vertical locations, are calculated by taking the average of the immediately neighbouring pixel at unit horizontal and unit vertical location (pixel A) and the immediately neighbouring $\frac{1}{2}$ resolution sub-pixel at half horizontal and unit vertical location (sub-pixel b), i.e. according to $d=(A+b)/2$. Values for $\frac{1}{4}$ resolution sub-pixels d located at quarter horizontal and half vertical locations, are calculated by taking the average of the immediately neighbouring $\frac{1}{2}$ resolution sub-pixels c which lie at unit horizontal and half vertical location and half horizontal and half vertical locations respectively, i.e. according to $d=(c_1+c_2)/2$. Again operator / indicates division with truncation.

4. Values for the $\frac{1}{4}$ resolution sub-pixels labelled e are calculated using linear interpolation and the values of the nearest pixels and/or $\frac{1}{2}$ resolution sub-pixels in the vertical direction. In particular, $\frac{1}{4}$ resolution sub-pixels e at unit horizontal and quarter vertical locations are calculated by taking the average of the immediately neighbouring pixel at unit horizontal and unit vertical location (pixel A) and the immediately neighbouring sub-pixel at unit horizontal and half vertical location (sub-pixel c) according to $e=(A+c)/2$. $\frac{1}{4}$ resolution sub-pixels e_3 at half horizontal and quarter vertical locations are calculated by taking the average of the immediately neighbouring sub-pixel at half horizontal and unit vertical location (sub-pixel b) and the immediately neighbouring sub-pixel at half horizontal and half vertical location (sub-pixel c),

11

according to $e=(b+c)/2$. Furthermore, $\frac{1}{4}$ resolution sub-pixels e at quarter horizontal and quarter vertical locations are calculated by taking the average of the immediately neighbouring sub-pixels at quarter horizontal and unit vertical location and the corresponding sub-pixel at quarter horizontal and half vertical location (sub-pixels d), according to $e=(d_1+d_2)/2$. Once more, operator $/$ indicates division with truncation.

5. The value for $\frac{1}{4}$ resolution sub-pixel f is interpolated by averaging the values of the 4 closest pixels values at unit horizontal and vertical locations, according to $f=(A_1+A_2+A_3+A_4+2)/4$, where pixels A_1 , A_2 , A_3 and A_4 are the four nearest original pixels.

A disadvantage of TML5 is that the decoder is computationally complex. This results from the fact that TML5 uses an approach in which interpolation of $\frac{1}{4}$ resolution sub-pixel values depends upon the interpolation of $\frac{1}{2}$ resolution sub-pixel values. This means that in order to interpolate the values of the $\frac{1}{4}$ resolution sub-pixels, the values of the $\frac{1}{2}$ resolution sub-pixels from which they are determined must be calculated first. Furthermore, since the values of some of the $\frac{1}{4}$ resolution sub-pixels depend upon the interpolated values obtained for other $\frac{1}{4}$ resolution sub-pixels, truncation of the $\frac{1}{4}$ resolution sub-pixel values has a deleterious effect on the precision of some of the $\frac{1}{4}$ resolution sub-pixel values. Specifically, the $\frac{1}{4}$ resolution sub-pixel values are less precise than they would be if calculated from values that had not been truncated and clipped. Another disadvantage of TML5 is that it is necessary to store the values of the $\frac{1}{2}$ resolution sub-pixels in order to interpolate the $\frac{1}{4}$ resolution sub-pixel values. Therefore, excess memory is required to store a result which is not ultimately required.

The sub-pixel value interpolation scheme according to TML6, referred to herein as direct interpolation, will now be described. In the encoder the interpolation method according to TML6 works like the previously described TML5 interpolation method, except that maximum precision is retained throughout. This is achieved by using intermediate values which are neither rounded nor clipped. A step-by-step description of interpolation method according to TML6 as applied in the encoder is given below with reference to FIGS. 13a, 13b and 13c.

1. The value for the sub-pixel at half unit horizontal and unit vertical location, that is $\frac{1}{2}$ resolution sub-pixel b in FIG. 13a, is obtained by first calculating an intermediate value b using a six tap filter. The filter calculates b based upon the values of the 6 pixels (A_1 to A_6) situated in a row at unit horizontal locations and unit vertical locations symmetrically about b , as shown in FIG. 13b, according to the formula $b=(A_1-5A_2+20A_3+20A_4-5A_5+A_6)$. The final value of b is then calculated as $b=(b+16)/32$ and is clipped to lie in the range $[0, 2^n-1]$. As before, the operator $/$ denotes division with truncation.
2. Values for the $\frac{1}{2}$ resolution sub-pixels labelled c are obtained by first calculating intermediate values c . Referring to FIG. 13c, an intermediate value c for the $\frac{1}{2}$ resolution sub-pixel c located at unit horizontal and half vertical location is calculated based upon the values of the 6 pixels (A_1 to A_6) situated in a column at unit horizontal locations and unit vertical locations symmetrically about c , according to the formula $c=(A_1-5A_2+20A_3+20A_4-5A_5+A_6)$. The final value for the $\frac{1}{2}$ resolution sub-pixel c located at unit horizontal and half vertical location is then calculated according to $c=(c+16)/32$. Similarly, an intermediate value c for the $\frac{1}{2}$ resolution sub-pixel c at half horizontal and half vertical location is calculated according to $c=(b_1-5b_2+20b_3+20b_4-5b_5+b_6)$. A final value for

12

this $\frac{1}{2}$ resolution sub-pixel is then calculated according to $(c+512)/1024$. Again, the operator $/$ denotes division with truncation and the values calculated for $\frac{1}{2}$ resolution sub-pixels c are further clipped to lie in the range $[0, 2^n-1]$.

3. Values for the $\frac{1}{4}$ resolution sub-pixels labelled d are calculated as follows. Values for $\frac{1}{4}$ resolution sub-pixels d located at quarter horizontal and unit vertical locations, are calculated from the value of the immediately neighbouring pixel at unit horizontal and unit vertical location (pixel A) and the intermediate value b calculated in step (1) for the immediately neighbouring $\frac{1}{2}$ resolution sub-pixel at half horizontal and unit vertical location ($\frac{1}{2}$ resolution sub-pixel b), according to $d=(32A+b+32)/64$. Values for $\frac{1}{4}$ resolution sub-pixels d located at quarter horizontal and half vertical locations, are interpolated using the intermediate values c calculated for the immediately neighbouring $\frac{1}{2}$ resolution sub-pixels c which lie at unit horizontal and half vertical location and half horizontal and half vertical locations respectively, according to $d=(32c_1+c_2+1024)/2048$. Again operator $/$ indicates division with truncation and the finally obtained $\frac{1}{4}$ resolution sub-pixel values d are clipped to lie in the range $[0, 2^n-1]$.
 4. Values for the $\frac{1}{4}$ resolution sub-pixels labelled e are calculated as follows. Values for $\frac{1}{4}$ resolution sub-pixels e located at unit horizontal and quarter vertical locations are calculated from the value of the immediately neighbouring pixel at unit horizontal and unit vertical location (pixel A) and the intermediate value c calculated in step (2) for the immediately neighbouring $\frac{1}{2}$ resolution sub-pixel at unit horizontal and half vertical location, according to $e=(32A+c+32)/64$. Values for $\frac{1}{4}$ resolution sub-pixels e located at half horizontal and quarter vertical locations are calculated from the intermediate value b calculated in step (1) for the immediately neighbouring $\frac{1}{2}$ resolution sub-pixel at half horizontal and unit vertical location and the intermediate value c calculated in step (2) for the immediately neighbouring $\frac{1}{2}$ resolution sub-pixel at half horizontal and half vertical location, according to $e=(32b+c+1024)/2048$. Once more, operator $/$ indicates division with truncation and the finally obtained $\frac{1}{4}$ resolution sub-pixel values e are clipped to lie in the range $[0, 2^n-1]$.
 5. Values for $\frac{1}{4}$ resolution sub-pixels labelled g are computed using the value of the nearest original pixel A and the intermediate values of the three nearest neighbouring $\frac{1}{2}$ resolution sub-pixels, according to $g=(1024A+32b+32c_1+c_2+2048)/4096$. As before, operator $/$ indicates division with truncation and the finally obtained for $\frac{1}{4}$ resolution sub-pixel values g are clipped to lie in the range $[0, 2^n-1]$.
 6. The value for $\frac{1}{4}$ resolution sub-pixel f is interpolated by averaging the values of the 4 closest pixels at unit horizontal and vertical locations, according to $f=(A_1+A_2+A_3+A_4+2)/4$, where the locations of pixels A_1 , A_2 , A_3 and A_4 are the four nearest original pixels.
- In the decoder, sub-pixel values can be obtained directly by applying 6-tap filters in horizontal and vertical directions. In the case of $\frac{1}{4}$ sub-pixel resolution, referring to FIG. 13a, the filter coefficients applied to pixels and sub-pixels at unit vertical location are $[0, 0, 64, 0, 0, 0]$ for a set of six pixels A , $[1, -5, 52, 20, -5, 1]$ for a set of six sub-pixels d , $[2, -10, 40, 40, -10, 2]$ for a set of six sub-pixels b , and $[1, -5, 20, 52, -5, 1]$ for a set of six sub-pixels d . These filter coefficients are applied to respective sets of pixels or sub-pixels in the same row as the sub-pixel values being interpolated.

13

After applying the filters in the horizontal and vertical directions, interpolated value c is normalized according to $c=(c+2048)/4096$ and clipped to lie in the range $[0, 2^n-1]$. When a motion vector points to an integer pixel position in either the horizontal or vertical direction, many zero coefficients are used. In a practical implementation of TML6, different branches are used in the software which are optimised for the different sub-pixel cases so that there are no multiplications by zero coefficients.

It should be noted that in TML6, $\frac{1}{4}$ resolution sub-pixel values are obtained directly using the intermediate values referred to above and are not derived from rounded and clipped values for $\frac{1}{2}$ resolution sub-pixels. Therefore, in obtaining the $\frac{1}{4}$ resolution sub-pixel values, it is not necessary to calculate final values for any of the $\frac{1}{2}$ resolution sub-pixels. Specifically, it is not necessary to carry out the truncation and clipping operations associated with the calculation of final values for the $\frac{1}{2}$ resolution sub-pixels. Neither is it necessary to have stored final values for $\frac{1}{2}$ resolution sub-pixels for use in the calculation of the $\frac{1}{4}$ resolution sub-pixel values. Therefore TML6 is computationally less complex than TML5, as fewer truncating and clipping operations are required. However, a disadvantage of TML6 is that high precision arithmetic is required both in the encoder and in the decoder. High precision interpolation requires more silicon area in ASICs and requires more computations in some CPUs. Furthermore, implementation of direct interpolation as specified in TML6 in an on-demand fashion has a high memory requirement. This is an important factor, particularly in embedded devices.

In view of the previously presented discussion, it should be appreciated that due to the different requirements of the video encoder and decoder with regard to sub-pixel interpolation, there exists a significant problem in developing a method of sub-pixel value interpolation capable of providing satisfactory performance in both the encoder and decoder. Furthermore, neither of the current test models (TML5, TML6) described in the foregoing can provide a solution that is optimum for application in both encoder and decoder.

SUMMARY OF THE INVENTION

According to a first aspect of the invention there is provided method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N , the method comprising:

a) when values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) when values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations are required, interpolating such values directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and

c) when a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location is required, inter-

14

polating such a value by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m , n , p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

Preferably a first and a second weight are used in the weighted average referred to in (c), the relative magnitudes of the weights being inversely proportional to the (straight-line diagonal) proximity of the first and the second sub-pixel or pixel to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

In a situation where the first and the second sub-pixel or pixel are symmetrically located with respect to (equidistant from) the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location, the first and second weights may have equal values.

The first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations in step b) may be used when a sub-pixel at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^N$ unit vertical location is required.

The second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations in step b) may be used when a sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location is required.

In one embodiment, when values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and unit vertical locations, and $\frac{1}{2}^N$ horizontal and $\frac{1}{2}^{N-1}$ vertical locations are required, such values are interpolated by taking the average of the values of a first pixel or sub-pixel located at a vertical location corresponding to that of the sub-pixel being calculated and unit horizontal location and a second pixel or sub-pixel located at a vertical location corresponding to that of the sub-pixel being calculated and $\frac{1}{2}^{N-1}$ unit horizontal location.

When values for sub-pixels at unit horizontal and $\frac{1}{2}^N$ unit vertical locations, and $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are required, they may be interpolated by taking the average of the values of a first pixel or sub-pixel located at a horizontal location corresponding to that of the sub-pixel being calculated and unit vertical location and a second pixel or sub-pixel located at a horizontal location corresponding to that of the sub-pixel being calculated and $\frac{1}{2}^{N-1}$ unit vertical location.

Values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations may be interpolated by taking the average of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

Values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations may be interpolated by taking the average of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

Values for half of the sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations may be interpolated by taking the average of a first pair of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location and values for the other half of the sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are interpolated by taking the average of a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

15

Values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are alternately interpolated for one such sub-pixel by taking the average of a first pair of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location and values and for a neighbouring such sub-pixel by taking the average of a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

The sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations may be alternately interpolated in a horizontal direction.

The sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations may be alternately interpolated in a horizontal direction.

When values for some sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are required, such values may be interpolated by taking the average of a plurality of nearest neighbouring pixels.

At least one of step a) and step b) interpolating sub-pixel values directly using weighted sums may involve the calculation of an intermediate value for the sub-pixel values having a dynamic range greater than the specified dynamic range.

The intermediate value for a sub-pixel having $\frac{1}{2}^{N-1}$ sub-pixel resolution may be used the calculation of a sub-pixel value having $\frac{1}{2}^N$ sub-pixel resolution.

According to a second aspect of the invention, there is provided a method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the method comprising:

a) when values for sub-pixels at half unit horizontal and unit vertical locations, and unit horizontal and half unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) when values for sub-pixels at half unit horizontal and half unit vertical locations are required, interpolating such values directly using a weighted sum of values for sub-pixels residing at half unit horizontal and unit vertical locations calculated according to step (a); and

c) when values for sub-pixels at quarter unit horizontal and quarter unit vertical locations are required, interpolating such values by taking the average of at least one pair of a first pair of values of a sub-pixel located at a half unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and half unit vertical location and a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a half unit horizontal and half unit vertical location.

According to a third aspect of the invention, there is provided a method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to

16

$\frac{1}{2}^x$ where x is a positive integer having a maximum value N, the method comprising:

a) when values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) when a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required, interpolating such a value directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

The sub-pixels used in the first weighted sum may be sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and the first weighted sum may be used to interpolate a value for a sub-pixel at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^N$ unit vertical location.

The sub-pixels used in the second weighted sum may be sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations and the second weighted sum may be used to interpolate a value for a sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

When values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are required, they may be interpolated by taking the average of at least one pair of a first pair of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location and a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

In the foregoing, N may be equal an integer selected from a list consisting of the values 2, 3, and 4.

Sub-pixels at quarter unit horizontal location are to be interpreted as being sub-pixels having as their left-hand nearest neighbour a pixel at unit horizontal location and as their right-hand nearest neighbour a sub-pixel at half unit horizontal location as well as sub-pixels having as their left-hand nearest neighbour a sub-pixel at half unit horizontal location and as their right-hand nearest neighbour a pixel at unit horizontal location. Correspondingly, sub-pixels at quarter unit vertical location are to be interpreted as being sub-pixels having as their upper nearest neighbour a pixel at unit vertical location and as their lower nearest neighbour a sub-pixel at half unit vertical location as well as sub-pixels having as their upper nearest neighbour a sub-pixel at half unit vertical location and as their lower nearest neighbour a pixel at unit vertical location.

The term dynamic range, refers to the range of values which the sub-pixel values and the weighted sums can take.

Preferably changing the dynamic range, whether by extending it or reducing it, means changing the number of bits which are used to represent the dynamic range.

In an embodiment of the invention, the method is applied to an image that is sub-divided into a number of image blocks. Preferably each image block comprises four corners, each corner being defined by a pixel located at a unit horizontal and unit vertical location. Preferably the method is applied to each image block as the block becomes available for sub-pixel value interpolation. Alternatively, sub-pixel value interpolation according to the method of the invention is performed once all image blocks of an image have become available for sub-pixel value interpolation.

17

Preferably the method is used in video encoding. Preferably the method is used in video decoding.

In one embodiment of the invention, when used in encoding, the method is carried out as before-hand interpolation, in which values for all sub-pixels at half unit locations and values for all sub-pixels at quarter unit locations are calculated and stored before being subsequently used in the determination of a prediction frame during motion predictive coding. In alternative embodiments, the method is carried out as a combination of before-hand and on-demand interpolation. In this case, a certain proportion or category of sub-pixel values is calculated and stored before being used in the determination of a prediction frame and certain other sub-pixel values are calculated only when required during motion predictive coding.

Preferably, when the method is used in decoding, sub-pixels are only interpolated when their need is indicated by a motion vector.

According to a fourth aspect of the invention, there is provided a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the video coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the interpolator being adapted to:

a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and

c) interpolate a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

The video coder may comprise a video encoder. It may comprise a video decoder. There may be a codec comprising both the video encoder and the video decoder.

According to a fifth aspect of the invention, there is provided a communications terminal comprising a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the video coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to

18

$\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the interpolator being adapted to:

a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and

c) interpolate a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

The communications terminal may comprise a video encoder. It may comprise a video decoder. Preferably, it comprises a video codec comprising a video encoder and a video decoder.

Preferably the communications terminal comprising a user interface, a processor and at least one of a transmitting block and a receiving block, and a video coder according to at least one of the third and fourth aspects of the invention. Preferably the processor controls the operation of the transmitting block and/or the receiving block and the video coder.

According to a sixth aspect of the invention, there is provided a telecommunications system comprising a communications terminal and a network, the telecommunications network and the communications terminal being connected by a communications link over which coded video can be transmitted, the communications terminal comprising a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the video coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the interpolator being adapted to:

a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and

c) interpolate a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and

the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

Preferably the telecommunications system is a mobile telecommunications system comprising a mobile communications terminal and a wireless network, the connection between the mobile communications terminal and the wireless network being formed by a radio link. Preferably the network enables the communications terminal to communicate with other communications terminals connected to the network over communications links between the other communications terminals and the network.

According to a seventh aspect of the invention, there is provided a telecommunications system comprising a communications terminal and a network, the telecommunications network and the communications terminal being connected by a communications link over which coded video can be transmitted, the network comprising a video coder for coding for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the video coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the interpolator being adapted to:

a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and

c) interpolate a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

According to an eighth aspect of the invention there is provided a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the resolution of the sub-pixels being determined by a positive integer N, the interpolator being adapted to:

a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) interpolate a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

The interpolator may be further adapted to form the first weighted sum using the values of sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and to use the first weighted sum to interpolate a value for a sub-pixel at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^N$ unit vertical location.

The interpolator may be further adapted to form the second weighted sum using the values of sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations and to use the second weighted sum to interpolate a value for a sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

The interpolator may be further adapted to interpolate values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations by taking the average of at least one pair of a first pair of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location and a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

According to a ninth aspect of the invention there is provided a communications terminal comprising a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the resolution of the sub-pixels being determined by a positive integer N, the interpolator being adapted to:

a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) interpolate a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

According to a tenth aspect of the invention there is provided a telecommunications system comprising a communications terminal and a network, the telecommunications network and the communications terminal being connected by a communications link over which coded video can be transmitted, the communications terminal comprising a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the resolution of the sub-pixels being determined by a positive integer N, the interpolator being adapted to:

a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) interpolate a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

According to an eleventh aspect of the invention there is provided a telecommunications system comprising a communications terminal and a network, the telecommunications network and the communications terminal being connected by a communications link over which coded video can be transmitted, the network comprising a video coder for coding for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the resolution of the sub-pixels being determined by a positive integer N, the interpolator being adapted to:

a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;

b) interpolate a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

BRIEF DESCRIPTION OF THE FIGURES

An embodiment of the invention will now be described by way of example only with reference to the accompanying drawings in which:

FIG. 1 shows a video encoder according to the prior art;

FIG. 2 shows a video decoder according to the prior art;

FIG. 3 shows the types of frames used in video encoding;

FIGS. 4a, 4b, and 4c show steps in block-matching;

FIG. 5 illustrates the process of motion estimation to sub-pixel resolution;

FIG. 6 shows a terminal device comprising video encoding and decoding equipment in which the method of the invention may be implemented;

FIG. 7 shows a video encoder according an embodiment of the present invention;

FIG. 8 shows a video decoder according to an embodiment of the present invention;

FIG. 11 shows a schematic diagram of a mobile telecommunications network according to an embodiment of the present invention;

FIG. 12a shows a notation for describing pixel and sub-pixel locations specific to TML5;

FIG. 12b shows interpolation of a half resolution sub-pixels;

FIG. 12c shows interpolation of a half resolution sub-pixels;

FIG. 13a shows a notation for describing pixel and sub-pixel locations specific to TML6;

FIG. 13b shows interpolation of a half resolution sub-pixels;

FIG. 13c shows interpolation of a half resolution sub-pixels;

FIG. 14 shows a notation for describing pixel and sub-pixel locations specific to the invention;

FIG. 14b shows interpolation of a half resolution sub-pixels according to the invention;

FIG. 14c shows interpolation of a half resolution sub-pixels according to the invention;

FIG. 15 shows possible choices of diagonal interpolation for sub-pixels;

FIG. 16 shows the half resolution sub-pixel values required to calculate other half resolution sub-pixel values;

FIG. 17a shows the half resolution sub-pixel values that must be calculated in order to interpolate values for quarter resolution sub-pixels in an image block using the interpolation method of TML5;

FIG. 17b shows the half resolution sub-pixel values that must be calculated in order to interpolate values for quarter resolution sub-pixels in an image block using the interpolation method according to the invention;

FIG. 18a shows the numbers of half resolution sub-pixels that must be calculated in order to obtain values for quarter resolution sub-pixels within an image block using the sub-pixel value interpolation method according to TML5;

FIG. 18b shows the numbers of half resolution sub-pixels that must be calculated in order to obtain values for quarter resolution sub-pixels within an image block using the sub-pixel value interpolation method according to the invention;

FIG. 19 shows a numbering scheme for each of the 15 sub-pixel positions;

FIG. 20 shows nomenclature used to describe pixels, half resolution sub-pixels, quarter resolution sub-pixels and eighth resolution sub-pixels

FIG. 21a shows the diagonal direction to be used in the interpolation of each eighth resolution sub-pixel in an embodiment of the invention;

FIG. 21b shows the diagonal direction to be used in the interpolation of each eighth resolution sub-pixel in another embodiment of the invention; and

FIG. 22 shows nomenclature used to describe eighth resolution sub-pixels within an image.

DETAILED DESCRIPTION

FIGS. 1 to 5, 12a, 12b, 12c, 13a, 13b, and 13c have been described in the foregoing.

FIG. 6 presents a terminal device comprising video encoding and decoding equipment which may be adapted to operate in accordance with the present invention. More precisely, the figure illustrates a multimedia terminal 60 implemented according to ITU-T recommendation H.324. The terminal can be regarded as a multimedia transceiver device. It includes elements that capture, encode and multiplex multimedia data streams for transmission via a communications network, as well as elements that receive, de-multiplex, decode and display received multimedia content. ITU-T recommendation H.324 defines the overall operation of the terminal and refers to other recommendations that govern the operation of its various constituent parts. This kind of multimedia terminal can be used in real-time applications such as conversational videotelephony, or non real-time applications such as the retrieval/streaming of video clips, for example from a multimedia content server in the Internet.

In the context of the present invention, it should be appreciated that the H.324 terminal shown in FIG. 6 is only

one of a number of alternative multimedia terminal implementations suited to application of the inventive method. It should also be noted that a number of alternatives exist relating to the location and implementation of the terminal equipment. As illustrated in FIG. 6, the multimedia terminal may be located in communications equipment connected to a fixed line telephone network such as an analogue PSTN (Public Switched Telephone Network). In this case the multimedia terminal is equipped with a modem 71, compliant with ITU-T recommendations V.8, V.34 and optionally V.8bis. Alternatively, the multimedia terminal may be connected to an external modem. The modem enables conversion of the multiplexed digital data and control signals produced by the multimedia terminal into an analogue form suitable for transmission over the PSTN. It further enables the multimedia terminal to receive data and control signals in analogue form from the PSTN and to convert them into a digital data stream that can be demultiplexed and processed in an appropriate manner by the terminal.

An H.324 multimedia terminal may also be implemented in such a way that it can be connected directly to a digital fixed line network, such as an ISDN (Integrated Services Digital Network). In this case the modem 71 is replaced with an ISDN user-network interface. In FIG. 6, this ISDN user-network interface is represented by alternative block 72.

H.324 multimedia terminals may also be adapted for use in mobile communication applications. If used with a wireless communication link, the modem 71 can be replaced with any appropriate wireless interface, as represented by alternative block 73 in FIG. 6. For example, an H.324/M multimedia terminal can include a radio transceiver enabling connection to the current 2nd generation GSM mobile telephone network, or the proposed 3rd generation UMTS (Universal Mobile Telephone System).

It should be noted that in multimedia terminals designed for two-way communication, that is for transmission and reception of video data, it is advantageous to provide both a video encoder and video decoder implemented according to the present invention. Such an encoder and decoder pair is often implemented as a single combined functional unit, referred to as a 'codec'.

Because a video encoder according to the invention performs motion compensated video encoding to sub-pixel resolution using a specific interpolation scheme and a particular combination of before-hand and on-demand sub-pixel value interpolation, it is generally necessary for a video decoder of a receiving terminal to be implemented in a manner compatible with the encoder of the transmitting terminal which formed the compressed video data stream. Failure to ensure this compatibility may have an adverse effect on the quality of the motion compensation and the accuracy of reconstructed video frames.

A typical H.324 multimedia terminal will now be described in further detail with reference to FIG. 6.

The multimedia terminal 60 includes a variety of elements referred to as 'terminal equipment'. This includes video, audio and telematic devices, denoted generically by reference numbers 61, 62 and 63, respectively. The video equipment 61 may include, for example, a video camera for capturing video images, a monitor for displaying received video content and optional video processing equipment. The audio equipment 62 typically includes a microphone, for example for capturing spoken messages, and a loudspeaker for reproducing received audio content. The audio equipment may also include additional audio processing units.

The telematic equipment 63, may include a data terminal, keyboard, electronic whiteboard or a still image transceiver, such as a fax unit.

The video equipment 61 is coupled to a video codec 65. The video codec 65 comprises a video encoder and a corresponding video decoder both implemented according to the invention. Such an encoder and a decoder will be described in the following. The video codec 65 is responsible for encoding captured video data in an appropriate form for further transmission over a communications link and decoding compressed video content received from the communications network. In the example illustrated in FIG. 6, the video codec is implemented according to ITU-T recommendation H.263, with appropriate modifications to implement the sub-pixel value interpolation method according to the invention in both the encoder and the decoder of the video codec.

Similarly, the terminal's audio equipment is coupled to an audio codec, denoted in FIG. 6 by reference number 66. Like the video codec, the audio codec comprises an encoder/decoder pair. It converts audio data captured by the terminal's audio equipment into a form suitable for transmission over the communications link and transforms encoded audio data received from the network back into a form suitable for reproduction, for example on the terminal's loudspeaker. The output of the audio codec is passed to a delay block 67. This compensates for the delays introduced by the video coding process and thus ensures synchronisation of audio and video content.

The system control block 64 of the multimedia terminal controls end-to-network signalling using an appropriate control protocol (signalling block 68) to establish a common mode of operation between a transmitting and a receiving terminal. The signalling block 68 exchanges information about the encoding and decoding capabilities of the transmitting and receiving terminals and can be used to enable the various coding modes of the video encoder. The system control block 64 also controls the use of data encryption. Information regarding the type of encryption to be used in data transmission is passed from encryption block 69 to the multiplexer/de-multiplexer (MUX/DMUX unit) 70.

During data transmission from the multimedia terminal, the MUX/DMUX unit 70 combines encoded and synchronised video and audio streams with data input from the telematic equipment 63 and possible control data, to form a single bit-stream. Information concerning the type of data encryption (if any) to be applied to the bit-stream, provided by encryption block 69, is used to select an encryption mode. Correspondingly, when a multiplexed and possibly encrypted multimedia bit-stream is being received, MUX/DMUX unit 70 is responsible for decrypting the bit-stream, dividing it into its constituent multimedia components and passing those components to the appropriate codec(s) and/or terminal equipment for decoding and reproduction.

It should be noted that the functional elements of the multimedia terminal, video encoder, decoder and video codec according to the invention can be implemented as software or dedicated hardware, or a combination of the two. The video encoding and decoding methods according to the invention are particularly suited for implementation in the form of a computer program comprising machine-readable instructions for performing the functional steps of the invention. As such, the encoder and decoder according to the invention may be implemented as software code stored on a storage medium and executed in a computer, such as a personal desktop computer, in order to provide that computer with video encoding and/or decoding functionality.

If the multimedia terminal **60** is a mobile terminal, that is if it is equipped with a radio transceiver **73**, it will be understood by those skilled in the art that it may also comprise additional elements. In one embodiment it comprises a user interface having a display and a keyboard, which enables operation of the multimedia terminal **60** by a user, together with necessary functional blocks including a central processing unit, such as a microprocessor, which controls the blocks responsible for different functions of the multimedia terminal, a random access memory RAM, a read only memory ROM, and a digital camera. The microprocessor's operating instructions, that is program code corresponding to the basic functions of the multimedia terminal **60**, is stored in the read-only memory ROM and can be executed as required by the microprocessor, for example under control of the user. In accordance with the program code, the microprocessor uses the radio transceiver **73** to form a connection with a mobile communication network, enabling the multimedia terminal **60** to transmit information to and receive information from the mobile communication network over a radio path.

The microprocessor monitors the state of the user interface and controls the digital camera. In response to a user command, the microprocessor instructs the camera to record digital images into the RAM. Once an image is captured, or alternatively during the capturing process, the microprocessor segments the image into image segments (for example macroblocks) and uses the encoder to perform motion compensated encoding for the segments in order to generate a compressed image sequence as explained in the foregoing description. A user may command the multimedia terminal **60** to display the captured images on its display or to send the compressed image sequence using the radio transceiver **73** to another multimedia terminal, a video telephone connected to a fixed line network (PSTN) or some other telecommunications device. In a preferred embodiment, transmission of image data is started as soon as the first segment is encoded so that the recipient can start a corresponding decoding process with a minimum delay.

FIG. **11** is a schematic diagram of a mobile telecommunications network according to an embodiment of the invention. Multimedia terminals MS are in communication with base stations BTS by means of a radio link. The base stations BTS are further connected, through a so-called Abis interface, to a base station controller BSC, which controls and manages several base stations.

The entity formed by a number of base stations BTS (typically, by a few tens of base stations) and a single base station controller BSC, controlling the base stations, is called a base station subsystem BSS. Particularly, the base station controller BSC manages radio communication channels and handovers. The base station controller BSC is also connected, through a so-called A interface, to a mobile services switching centre MSC, which co-ordinates the formation of connections to and from mobile stations. A further connection is made, through the mobile service switching centre MSC, to outside the mobile communications network. Outside the mobile communications network there may further reside other network(s) connected to the mobile communications network by gateway(s) GTW, for example the Internet or a Public Switched Telephone Network (PSTN). In such an external network, or within the telecommunications network, there may be located video decoding or encoding stations, such as computers PC. In an embodiment of the invention, the mobile telecommunications network comprises a video server VSRVR to provide video data to a MS subscribing to such a service. The video

data is compressed using the motion compensated video compression method as described in the foregoing. The video server may function as a gateway to an online video source or it may comprise previously recorded video clips. Typical videotelephony applications may involve, for example, two mobile stations or one mobile station MS and a videotelephone connected to the PSTN, a PC connected to the Internet or a H.261 compatible terminal connected either to the Internet or to the PSTN.

FIG. **7** shows a video encoder **700** according to an embodiment the invention. FIG. **8** shows a video decoder **800** according to an embodiment the invention.

The encoder **700** comprises an input **701** for receiving a video signal from a camera or other video source (not shown). It further comprises a DCT transformer **705**, a quantiser **706**, an inverse quantiser **709**, an inverse DCT transformer **710**, combiners **712** and **716**, a before-hand sub-pixel interpolation block **730**, a frame store **740** and an on-demand sub-pixel interpolation block **750**, implemented in combination with motion estimation block **760**. The encoder also comprises a motion field coding block **770** and a motion compensated prediction block **780**. Switches **702** and **714** are operated co-operatively by a control manager **720** to switch the encoder between an INTRA-mode of video encoding and an INTER-mode of video encoding. The encoder **700** also comprises a multiplexer unit (MUX/DMUX) **790** to form a single bit-stream from the various types of information produced by the encoder **700** for further transmission to a remote receiving terminal, or for example for storage on a mass storage medium such as a computer hard drive (not shown).

It should be noted that the presence and implementations of before-hand sub-pixel interpolation block **730** and on-demand sub-pixel value interpolation block **750** in the encoder architecture depend on the way in which the sub-pixel interpolation method according to the invention is applied. In embodiments of the invention in which before-hand sub-pixel value interpolation is not performed, encoder **700** does not comprise before-hand sub-pixel value interpolation block **730**. In other embodiments of the invention, only before-hand sub-pixel interpolation is performed and thus the encoder does not include on-demand sub-pixel value interpolation block **750**. In embodiments in which both before-hand and on-demand sub-pixel value interpolation are performed, both blocks **730** and **750** are present in the encoder **700**.

Operation of the encoder **700** according to the invention will now be described in detail. In the description, it will be assumed that each frame of uncompressed video, received from the video source at the input **701**, is received and processed on a macroblock-by-macroblock basis, preferably in raster-scan order. It will further be assumed that when the encoding of a new video sequence starts, the first frame of the sequence is encoded in INTRA-mode. Subsequently, the encoder is programmed to code each frame in INTER-format, unless one of the following conditions is met: 1) it is judged that the current frame being coded is so dissimilar from the reference frame used in its prediction that excessive prediction error information is produced; 2) a predefined INTRA frame repetition interval has expired; or 3) feedback is received from a receiving terminal indicating a request for a frame to be coded in INTRA format.

The occurrence of condition 1) is detected by monitoring the output of the combiner **716**. The combiner **716** forms a difference between the current macroblock of the frame being coded and its prediction, produced in the motion

compensated prediction block **780**. If a measure of this difference (for example a sum of absolute differences of pixel values) exceeds a predetermined threshold, the combiner **716** informs the control manager **720** via a control line **717** and the control manager **720** operates the switches **702** and **714** so as to switch the encoder **700** into INTRA coding mode. Occurrence of condition 2) is monitored by means of a timer or frame counter implemented in the control manager **720**, in such a way that if the timer expires, or the frame counter reaches a predetermined number of frames, the control manager **720** operates the switches **702** and **714** to switch the encoder into INTRA coding mode. Condition 3) is triggered if the control manager **720** receives a feedback signal from, for example, a receiving terminal, via control line **718** indicating that an INTRA frame refresh is required by the receiving terminal. Such a condition might arise, for example, if a previously transmitted frame were badly corrupted by interference during its transmission, rendering it impossible to decode at the receiver. In this situation, the receiver would issue a request for the next frame to be encoded in INTRA format, thus re-initialising the coding sequence.

It will further be assumed that the encoder and decoder are implemented in such a way as to allow the determination of motion vectors with a spatial resolution of up to quarter-pixel resolution. As will be seen in the following, finer levels of resolution are also possible.

Operation of the encoder **700** in INTRA coding mode will now be described. In INTRA-mode, the control manager **720** operates the switch **702** to accept video input from input line **719**. The video signal input is received macroblock by macroblock from input **701** via the input line **719** and each macroblock of original image pixels is transformed into DCT coefficients by the DCT transformer **705**. The DCT coefficients are then passed to the quantiser **706**, where they are quantised using a quantisation parameter QP. Selection of the quantisation parameter QP is controlled by the control manager **720** via control line **722**. Each DCT transformed and quantised macroblock that makes up the INTRA coded image information **723** of the frame is passed from the quantiser **706** to the MUX/DMUX **790**. The MUX/DMUX **790** combines the INTRA coded image information with possible control information (for example header data, quantisation parameter information, error correction data etc.) to form a single bit-stream of coded image information **725**. Variable length coding (VLC) is used to reduce redundancy of the compressed video bit-stream, as is known to those skilled in the art.

A locally decoded picture is formed in the encoder **700** by passing the data output by the quantiser **706** through inverse quantiser **709** and applying an inverse DCT transform **710** to the inverse-quantised data. The resulting data is then input to the combiner **712**. In INTRA mode, switch **714** is set so that the input to the combiner **712** via the switch **714** is set to zero. In this way, the operation performed by the combiner **712** is equivalent to passing the decoded image data formed by the inverse quantiser **709** and the inverse DCT transform **710** unaltered.

In embodiments of the invention in which before-hand sub-pixel value interpolation is performed, the output from combiner **712** is applied to before-hand sub-pixel interpolation block **730**. The input to the before-hand sub-pixel value interpolation block **730** takes the form of decoded image blocks. In the before-hand sub-pixel value interpolation block **730**, each decoded macroblock is subjected to sub-pixel interpolation in such a way that a predetermined sub-set of sub-pixel resolution sub-pixel values is calculated

according to the interpolation method of the invention and is stored together with the decoded pixel values in frame store **740**.

In embodiments in which before-hand sub-pixel interpolation is not performed, before-hand sub-pixel interpolation block is not present in the encoder architecture and the output from combiner **712**, comprising decoded image blocks, is applied directly to frame store **740**.

As subsequent macroblocks of the current frame are received and undergo the previously described coding and decoding steps in blocks **705**, **706**, **709**, **710**, **712**, a decoded version of the INTRA frame is built up in the frame store **740**. When the last macroblock of the current frame has been INTRA coded and subsequently decoded, the frame store **740** contains a completely decoded frame, available for use as a prediction reference frame in coding a subsequently received video frame in INTER format. In embodiments of the invention in which before-hand sub-pixel value interpolation is performed, the reference frame held in frame store **740** is at least partially interpolated to sub-pixel resolution.

Operation of the encoder **700** in INTER coding mode will now be described. In INTER coding mode, the control manager **720** operates switch **702** to receive its input from line **721**, which comprises the output of the combiner **716**. The combiner **716** forms prediction error information representing the difference between the current macroblock of the frame being coded and its prediction, produced in the motion compensated prediction block **780**. The prediction error information is DCT transformed in block **705** and quantised in block **706** to form a macroblock of DCT transformed and quantised prediction error information. Each macroblock of DCT transformed and quantised prediction error information is passed from the quantiser **706** to the MUX/DMUX unit **790**. The MUX/DMUX unit **790** combines the prediction error information **723** with motion coefficients **724** (described in the following) and control information (for example header data, quantisation parameter information, error correction data etc.) to form a single bit-stream of coded image information, **725**.

Locally decoded prediction error information for the each macroblock of the INTER coded frame is then formed in the encoder **700** by passing the encoded prediction error information **723** output by the quantiser **706** through the inverse quantiser **709** and applying an inverse DCT transform in block **710**. The resulting locally decoded macroblock of prediction error information is then input to combiner **712**. In INTER-mode, switch **714** is set so that the combiner **712** also receives motion predicted macroblocks for the current INTER frame, produced in the motion compensated prediction block **780**. The combiner **712** combines these two pieces of information to produce reconstructed image blocks for the current INTER frame.

As described above when considering INTRA coded frames, in embodiments of the invention in which before-hand sub-pixel value interpolation is performed, the output from combiner **712** is applied to the before-hand sub-pixel interpolation block **730**. Thus, the input to the before-hand sub-pixel value interpolation block **730** in INTER coding mode also takes the form of decoded image blocks. In the before-hand sub-pixel value interpolation block **730**, each decoded macroblock is subjected to sub-pixel interpolation in such a way that a predetermined sub-set of sub-pixel values is calculated according to the interpolation method of the invention and is stored together with the decoded pixel values in frame store **740**. In embodiments in which before-hand sub-pixel interpolation is not performed, before-hand

sub-pixel interpolation block is not present in the encoder architecture and the output from combiner 712, comprising decoded image blocks, is applied directly to frame store 740.

As subsequent macroblocks of the video signal are received from the video source and undergo the previously described coding and decoding steps in blocks 705, 706, 709, 710, 712, a decoded version of the INTER frame is built up in the frame store 740. When the last macroblock of the frame has been INTER coded and subsequently decoded, the frame store 740 contains a completely decoded frame, available for use as a prediction reference frame in encoding a subsequently received video frame in INTER format. In embodiments of the invention in which before-hand sub-pixel value interpolation is performed, the reference frame held in frame store 740 is at least partially interpolated to sub-pixel resolution.

Formation of a prediction for a macroblock of the current frame will now be described.

Any frame encoded in INTER format requires a reference frame for motion compensated prediction. This means, inter alia, that when encoding a video sequence, the first frame to be encoded, whether it is the first frame in the sequence, or some other frame, must be encoded in INTRA format. This, in turn, means that when the video encoder 700 is switched into INTER coding mode by control manager 720, a complete reference frame, formed by locally decoding a previously encoded frame, is already available in the frame store 740 of the encoder. In general, the reference frame is formed by locally decoding either an INTRA coded frame or an INTER coded frame.

The first step in forming a prediction for a macroblock of the current frame is performed by motion estimation block 760. The motion estimation block 760 receives the current macroblock of the frame being coded via line 727 and performs a block matching operation in order to identify a region in the reference frame which corresponds substantially with the current macroblock. According to the invention, the block-matching process is performed to sub-pixel resolution in a manner that depends on the implementation of the encoder 700 and the degree of before-hand sub-pixel interpolation performed. However, the basic principle behind the block-matching process is similar in all cases. Specifically, motion estimation block 760 performs block-matching by calculating difference values (e.g. sums of absolute differences) representing the difference in pixel values between the macroblock of the current frame under examination and candidate best-matching regions of pixels/sub-pixels in the reference frame. A difference value is produced for all possible offsets (e.g. quarter- or one eighth sub-pixel precision x, y displacements) between the macroblock of the current frame and candidate test region within a predefined search region of the reference frame and motion estimation block 760 determines the smallest calculated difference value. The offset between the macroblock in the current frame and the candidate test region of pixel values/sub-pixel values in the reference frame that yields the smallest difference value defines the motion vector for the macroblock in question. In certain embodiments of the invention, an initial estimate for the motion vector having unit pixel precision is first determined and then refined to a finer level of sub-pixel precision, as described in the foregoing.

In embodiments of the encoder in which before-hand sub-pixel value interpolation is not performed, all sub-pixel values required in the block matching process are calculated in on-demand sub-pixel value interpolation block 750.

Motion estimation block 760 controls on-demand sub-pixel value interpolation block 750 to calculate each sub-pixel value needed in the block-matching process in an on-demand fashion, as and when it is required. In this case, motion estimation block 760 may be implemented so as to perform block-matching as a one-step process, in which case a motion vector with the desired sub-pixel resolution is sought directly, or it may be implemented so as to perform block-matching as a two step process. If the two-step process is adopted, the first step may comprise a search for e.g. a full or half-pixel resolution motion vector and the second step is performed in order to refine the motion vector to the desired sub-pixel resolution. As block matching is an exhaustive process, in which blocks of nxm pixels in the current frame are compared one-by-one with blocks of nxm pixels or sub-pixels in the interpolated reference frame, it should be appreciated that a sub-pixel calculated in an on-demand fashion by the on-demand pixel interpolation block 750 may need to be calculated multiple times as successive difference values are determined. In a video encoder, this approach is not the most efficient possible in terms of computational complexity/burden.

In embodiments of the encoder which use only before-hand sub-pixel value interpolation, block-matching may be performed as a one step process, as all sub-pixel values of the reference frame required to determine a motion vector with the desired sub-pixel resolution are calculated before-hand in block 730 and stored in frame store 740. Thus, they are directly available for use in the block-matching process and can be retrieved as required from frame store 740 by motion estimation block 760. However, even in the case where all sub-pixel values are available from frame store 740, it is still more computationally efficient to perform block-matching as a two-step process, as fewer difference calculations are required. It should be appreciated that while full before-hand sub-pixel value interpolation reduces computational complexity in the encoder, it is not the most efficient approach in terms of memory consumption.

In embodiments of the encoder in which both before-hand and on-demand sub-pixel value interpolation are used, motion estimation block 760 is implemented in such a way that it can retrieve sub-pixel values previously calculated in before-hand sub-pixel value interpolation block 730 and stored in frame store 740 and further control on-demand sub-pixel value interpolation block 750 to calculate any additional sub-pixel values that may be required. The block-matching process may be performed as a one-step or a two-step process. If a two-step implementation is used, before-hand calculated sub-pixel values retrieved from frame store 740 may be used in the first step of the process and the second step may be implemented so as to use sub-pixel values calculated by on-demand sub-pixel value interpolation block 750. In this case, certain sub-pixel values used in the second step of the block matching process may need to be calculated multiple times as successive comparisons are made, but the number of such duplicate calculations is significantly less than if before-hand sub-pixel value calculation is not used. Furthermore, memory consumption is reduced with respect to embodiments in which only before-hand sub-pixel value interpolation is used.

Once the motion estimation block 760 has produced a motion vector for the macroblock of the current frame under examination, it outputs the motion vector to the motion field coding block 770. Motion field coding block 770 then approximates the motion vector received from motion estimation block 760 using a motion model. The motion model generally comprises a set of basis functions. More

specifically, the motion field coding block **770** represents the motion vector as a set of coefficient values (known as motion coefficients) which, when multiplied by the basis functions, form an approximation of the motion vector. The motion coefficients **724** are passed from motion field coding block **770** to motion compensated prediction block **780**. Motion compensated prediction block **780** also receives the pixel/sub-pixel values of the best-matching candidate test region of the reference frame identified by motion estimation block **760**. In FIG. 7, these values are shown to be passed via line **729** from on-demand sub-pixel interpolation block **750**. In alternative embodiments of the invention, the pixel values in question are provided from the motion estimation block **760** itself.

Using the approximate representation of the motion vector generated by motion field coding block **770** and the pixel/sub-pixel values of the best-matching candidate test region, motion compensated prediction block **780** produces a macroblock of predicted pixel values. The macroblock of predicted pixel values represents a prediction for the pixel values of the current macroblock generated from the interpolated reference frame. The macroblock of predicted pixel values is passed to the combiner **716** where it is subtracted from the new current frame in order to produce prediction error information **723** for the macroblock, as described in the foregoing.

The motion coefficients **724** formed by motion field coding block are also passed to the MUX/DMUX unit **790**, where they are combined with prediction error information **723** for the macroblock in question and possible control information from control manager **720** to form an encoded video stream **725** for transmission to a receiving terminal.

Operation of a video decoder **800** according to the invention will now be described. Referring to FIG. 8, the decoder **800** comprises a demultiplexing unit (MUX/DMUX) **810**, which receives the encoded video stream **725** from the encoder **700** and demultiplexes it, an inverse quantiser **820**, an inverse DCT transformer **830**, a motion compensated prediction block **840**, a frame store **850**, a combiner **860**, a control manager **870**, an output **880**, before-hand sub-pixel value interpolation block **845** and on-demand sub-pixel interpolation block **890** associated with the motion compensated prediction block **840**. In practice the control manager **870** of the decoder **800** and the control manager **720** of the encoder **700** may be the same processor. This may be the case if the encoder **700** and decoder **800** are part of the same video codec.

FIG. 8 shows an embodiment in which a combination of before-hand and on-demand sub-pixel value interpolation is used in the decoder. In other embodiments, only before-hand sub-pixel value interpolation is used, in which case decoder **800** does not include on-demand sub-pixel value interpolation block **890**. In a preferred embodiment of the invention, no before-hand sub-pixel value interpolation is used in the decoder and therefore before-hand sub-pixel value interpolation block **845** is omitted from the decoder architecture. If both before-hand and on-demand sub-pixel value interpolation are performed, the decoder comprises both blocks **845** and **890**.

The control manager **870** controls the operation of the decoder **800** in response to whether an INTRA or an INTER frame is being decoded. An INTRA/INTER trigger control signal, which causes the decoder to switch between decoding modes is derived, for example, from picture type information provided in the header portion of each compressed video frame received from the encoder. The INTRA/INTER

trigger control signal is passed to control manager **870** via control line **815**, together with other video codec control signals demultiplexed from the encoded video stream **725** by the MUX/DMUX unit **810**.

When an INTRA frame is decoded, the encoded video stream **725** is demultiplexed into INTRA coded macroblocks and control information. No motion vectors are included in the encoded video stream **725** for an INTRA coded frame. The decoding process is performed macroblock-by-macroblock. When the encoded information **723** for a macroblock is extracted from video stream **725** by MUX/DMUX unit **810**, it is passed to inverse quantiser **820**. The control manager controls inverse quantiser **820** to apply a suitable level of inverse quantisation to the macroblock of encoded information, according to control information provided in video stream **725**. The inverse quantised macroblock is then inversely transformed in the inverse DCT transformer **830** to form a decoded block of image information. Control manager **870** controls combiner **860** to prevent any reference information being used in the decoding of the INTRA coded macroblock. The decoded block of image information is passed to the video output **880** of the decoder.

In embodiments of the decoder which employ before-hand sub-pixel value interpolation, the decoded block of image information (i.e. pixel values) produced as a result of the inverse quantisation and inverse transform operations performed in blocks **820** and **830** is passed to before-hand sub-pixel value interpolation block **845**. Here, sub-pixel value interpolation is performed according to the method of the invention, the degree of before-hand sub-pixel value interpolation applied being determined by the details of the decoder implementation. In embodiments of the invention in which on-demand sub-pixel value interpolation is not performed, before-hand sub-pixel value interpolation block **845** interpolates all sub-pixel values. In embodiments that use a combination of before-hand and on-demand sub-pixel value interpolation, before-hand sub-pixel value interpolation block **845** interpolates a certain sub-set of sub-pixel values. This may comprise, for example, all sub-pixels at half-pixel locations, or a combination of sub-pixels at half-pixel and one quarter-pixel locations. In any case, after before-hand sub-pixel value interpolation, the interpolated sub-pixel values are stored in frame store **850**, together with the original decoded pixel values. As subsequent macroblocks are decoded, before-hand interpolated and stored, a decoded frame, at least partially interpolated to sub-pixel resolution is progressively assembled in the frame store **850** and becomes available for use as a reference frame for motion compensated prediction.

In embodiments of the decoder which do not employ before-hand sub-pixel value interpolation, the decoded block of image information (i.e. pixel values) produced as a result of the inverse quantisation and inverse transform operations performed on the macroblock in blocks **820** and **830** is passed directly to frame store **850**. As subsequent macroblocks are decoded and stored, a decoded frame, having unit pixel resolution is progressively assembled in the frame store **850** and becomes available for use as a reference frame for motion compensated prediction.

When an INTER frame is decoded, the encoded video stream **725** is demultiplexed into encoded prediction error information **723** for each macroblock of the frame, associated motion coefficients **724** and control information. Again, the decoding process is performed macroblock-by-macroblock. When the encoded prediction error information **723** for a macroblock is extracted from the video stream **725** by MUX/DMUX unit **810**, it is passed to inverse quantiser

820. Control manager **870** controls inverse quantiser **820** to apply a suitable level of inverse quantisation to the macroblock of encoded prediction error information, according to control information received in video stream **725**. The inverse quantised macroblock of prediction error information is then inversely transformed in the inverse DCT transformer **830** to yield decoded prediction error information for the macroblock.

The motion coefficients **724** associated with the macroblock in question are extracted from the video stream **725** by MUX/DMUX unit **810** and passed to motion compensated prediction block **840**, which reconstructs a motion vector for the macroblock using the same motion model as that used to encode the INTER-coded macroblock in encoder **700**. The reconstructed motion vector approximates the motion vector originally determined by motion estimation block **760** of the encoder. The motion compensated prediction block **840** of the decoder uses the reconstructed motion vector to identify the location of a block of pixel/sub-pixel values in a prediction reference frame stored in frame store **850**. The reference frame may be, for example, a previously decoded INTRA frame, or a previously decoded INTER frame. In either case, the block of pixel/sub-pixel values indicated by the reconstructed motion vector, represents the prediction of the macroblock in question.

The reconstructed motion vector may point to any pixel or sub-pixel. If the motion vector indicates that the prediction for the current macroblock is formed from pixel values (i.e. the values of pixels at unit pixel locations), these can simply be retrieved from frame store **850**, as the values in question are obtained directly during the decoding of each frame. If the motion vector indicates that the prediction for the current macroblock is formed from sub-pixel values, these must either be retrieved from frame store **850**, or calculated in on-demand sub-pixel interpolation block **890**. Whether sub-pixel values must be calculated, or can simply be retrieved from the frame store, depends on the degree of before-hand sub-pixel value interpolation used in the decoder.

In embodiments of the decoder that do not employ before-hand sub-pixel value interpolation, the required sub-pixel values are all calculated in on-demand sub-pixel value interpolation block **890**. On the other hand, in embodiments in which all sub-pixel values are interpolated before-hand, motion compensated prediction block **840** can retrieve the required sub-pixel values directly from the frame store **850**. In embodiments that use a combination before-hand and on-demand sub-pixel value interpolation, the action required in order to obtain the required sub-pixel values depends on which sub-pixel values are interpolated before-hand. Taking as an example an embodiment in which all sub-pixel values at half-pixel locations are calculated before-hand, it is evident that if a reconstructed motion vector for a macroblock points to a pixel at unit location or a sub-pixel at half-pixel location, all the pixel or sub-pixel values required to form the prediction for the macroblock are present in the frame store **850** and can be retrieved from there by motion compensated prediction block **840**. If, however, the motion vector indicates a sub-pixel at a quarter-pixel location, the sub-pixels required to form the prediction for the macroblock are not present in frame store **850** and are therefore calculated in on-demand sub-pixel value interpolation block **890**. In this case, on-demand sub-pixel value interpolation block **890** retrieves any pixel or sub-pixel required to perform the interpolation from frame store **850** and applies the interpolation method described below. Sub-pixel values calculated in on-demand sub-pixel value interpolation block **890** are passed to motion compensated prediction block **840**.

Once a prediction for a macroblock has been obtained, the prediction (that is, a macroblock of predicted pixel values) is passed from motion compensated prediction block **840** to combiner **860** where it combined with the decoded prediction error information for the macroblock to form a reconstructed image block which, in turn, is passed to the video output **880** of the decoder.

It should be appreciated that in practical implementations of encoder **700** and decoder **800**, the extent to which frames are before-hand sub-pixel interpolated, and thus the amount of on-demand sub-pixel value interpolation that is performed, can be chosen according to, or dictated by, the hardware implementation of the video encoder **700**, or the environment in which it is intended to be used. For example, if the memory available to the video encoder is limited, or memory must be reserved for other functions, it is appropriate to limit the amount of before-hand sub-pixel value interpolation that is performed. In other cases, where the microprocessor performing the video encoding operation has limited processing capacity, e.g. the number of operations per second that can be executed is comparatively low, it is more appropriate to restrict the amount of on-demand sub-pixel value interpolation that is performed. In a mobile communications environment, for example, when video encoding and decoding functionality is incorporated in a mobile telephone or similar wireless terminal for communication with a mobile telephone network, both memory and processing power may be limited. In this case a combination of before-hand and on-demand sub-pixel value interpolation may be the best choice to obtain an efficient implementation in the video encoder. In video decoder **800**, use of before-hand sub-pixel value is generally not preferred, as it typically results in the calculation of many sub-pixel values that are not actually used in the decoding process. However, it should be appreciated that although different amounts of before-hand and on-demand interpolation can be used in the encoder and decoder in order to optimise the operation of each, both encoder and decoder can be implemented so as to use the same division between before-hand and on-demand sub-pixel value interpolation.

Although the foregoing description does not describe the construction of bi-directionally predicted frames (B-frames) in the encoder **700** and the decoder **800**, it should be understood that in embodiments of the invention, such a capability may be provided. Provision of such capability is considered within the ability of one skilled in the art.

An encoder **700** or a decoder **800** according to the invention can be realised using hardware or software, or using a suitable combination of both. An encoder or decoder implemented in software may be, for example, a separate program or a software building block that can be used by various programs. In the above description and in the drawings, the functional blocks are represented as separate units, but the functionality of these blocks can be implemented, for example, in one software program unit.

The encoder **700** and decoder **800** can further be combined in order to form a video codec having both encoding and decoding functionality. In addition to being implemented in a multimedia terminal, such a codec may also be implemented in a network. A codes according to the invention may be a computer program or a computer program element, or it may be implemented at least partly using hardware.

The sub-pixel interpolation method used in the encoder **700** and decoder **800** according to the invention now be described in detail. The method will first be introduced at a

general conceptual level and then two preferred embodiments will be described. In the first preferred embodiment, sub-pixel value interpolation is performed to $\frac{1}{4}$ pixel resolution and in the second the method is extended to $\frac{1}{8}$ pixel resolution.

It should be noted that interpolation must produce identical values in the encoder and the decoder, but its implementation should be optimized for both entities separately. For example, in an encoder according to the first embodiment of the invention in which sub-pixel value interpolation is performed to $\frac{1}{4}$ pixel resolution, it is most efficient to calculate $\frac{1}{2}$ resolution pixels before-hand and to calculate values for $\frac{1}{4}$ resolution sub-pixels in an on-demand fashion, only when they are needed during motion estimation. This has the effect of limiting memory usage while keeping the computational complexity/burden at an acceptable level. In the decoder, on the other hand, it is advantageous not to pre-calculate any of the sub-pixels. Therefore, it should be appreciated that a preferred embodiment of the decoder does not include before-hand sub-pixel value interpolation block 845 and all sub-pixel value interpolation is performed in on-demand sub-pixel value interpolation block 890.

In the description of the interpolation method provided below, references are made to the pixel positions depicted in FIG. 14a. In this figure pixels labelled A represent original pixels (that is, pixels residing at unit horizontal and vertical locations). Pixels labelled with other letters represent sub-pixels that are to be interpolated. The description that follows will adhere to the previously introduced conventions regarding the description of pixel and sub-pixel locations.

Next, the steps required to interpolate all sub-pixel positions are described:

Values for the $\frac{1}{2}$ resolution sub-pixels labelled b are obtained by first calculating an intermediate value b using a Kth order filter, according to:

$$b = \sum_{i=1}^K x_i A_i \quad (9)$$

where x_i is a vector of filter coefficients, A_i is a corresponding vector of original pixel values A situated at unit horizontal and unit vertical locations, and K is an integer which defines the order of the filter. Thus, equation 9 can be re-expressed as:

$$b = x_1 A_1 + x_2 A_2 + x_3 A_3 + \dots + x_{K-1} A_{K-1} + x_K A_K \quad (10)$$

The values of the filter coefficients x_i and the order of the filter K may vary from embodiment to embodiment. Equally, different coefficient values may be used in the calculation of different sub-pixels within an embodiment. In other embodiments, the values of filter coefficients x_i and the order of the filter may depend on which of the $\frac{1}{2}$ resolution b sub-pixels is being interpolated. Pixels A_i are disposed symmetrically with respect to the $\frac{1}{2}$ resolution sub-pixel b being interpolated and are the closest neighbours of that sub-pixel. In the case of the $\frac{1}{2}$ resolution sub-pixel b situated at half horizontal and unit vertical location, pixels A_i are disposed horizontally with respect to b (as shown in FIG. 14b). If the $\frac{1}{2}$ resolution sub-pixel b situated at unit horizontal and half vertical location is being interpolated, pixels A_i are disposed vertically with respect to b (as shown in FIG. 14c).

A final value for $\frac{1}{2}$ resolution sub-pixel b is calculated by dividing intermediate value b by a constant scale₁, truncating it to obtain an integer number and clipping the result to lie

in the range $[0, 2^n - 1]$. In alternative embodiments of the invention rounding may be performed instead of truncation. Preferably, constant scale, is chosen to be equal to the sum of filter coefficients x_i .

A value for the $\frac{1}{2}$ resolution sub-pixel labelled c is also obtained by first calculating an intermediate value c using an Mth order filter, according to:

$$c = \sum_{i=1}^M y_i b_i \quad (11)$$

where y_i is a vector of filter coefficients, b_i is a corresponding vector of intermediate values b_i in the horizontal or vertical direction. i.e.:

$$c = y_1 b_1 + y_2 b_2 + y_3 b_3 + \dots + y_{M-1} b_{M-1} + y_M b_M \quad (12)$$

The values of the filter coefficients y_i and the order of the filter M may vary from embodiment to embodiment. Equally, different coefficient values may be used in the calculation of different sub-pixels within an embodiment. Preferably, the b values are intermediate values for $\frac{1}{2}$ resolution sub-pixels b which are disposed symmetrically with respect to $\frac{1}{2}$ resolution sub-pixel c and are the closest neighbours of sub-pixel c. In an embodiment of the invention, the $\frac{1}{2}$ resolution sub-pixels b are disposed horizontally with respect to sub-pixel c, in an alternative embodiment they are disposed vertically with respect to sub-pixel c.

A final value of $\frac{1}{2}$ resolution sub-pixel c is computed by dividing intermediate value c by a constant scale₂, truncating it to obtain an integer number and clipping the result to lie in the range $[0, 2^n - 1]$. In alternative embodiments of the invention rounding may be performed instead of truncation. Preferably, constant scale₂ is equal to scale₁ * scale₁.

It should be noted that the use of intermediate values b in the horizontal direction leads to the same result as using intermediate values b in the vertical direction.

There are two alternatives for interpolating values for the $\frac{1}{4}$ resolution sub-pixels labelled h. Both involve linear interpolation along a diagonal line linking $\frac{1}{2}$ resolution sub-pixels neighbouring the $\frac{1}{4}$ resolution sub-pixel h being interpolated. In a first embodiment, a value for sub-pixel h is calculated by averaging the values of the two $\frac{1}{2}$ resolution sub-pixels b closest to sub-pixel h. In a second embodiment, a value for sub-pixel h is calculated by averaging the values of the closest pixel A and the closest $\frac{1}{2}$ resolution sub-pixel c. It should be appreciated that this provides the possibility of using different combinations of diagonal interpolations to determine the values for sub-pixels h within the confines of different groups of 4 image pixels A. However, it should also be realised that the same combination should be used in both the encoder and the decoder in order to produce identical interpolation results. FIG. 15 depicts 4 possible choices of diagonal interpolation for sub-pixels h in adjacent groups of 4 pixels within an image. Simulations in the TML environment have verified that both embodiments result in similar compression efficiency. The second embodiment has higher complexity, since calculation of sub-pixel c requires calculation of several intermediate values. Therefore the first embodiment is preferred.

Values for $\frac{1}{4}$ resolution sub-pixels labelled d and g are calculated from the values of their nearest horizontal neighbours using linear interpolation. In other words, a value for $\frac{1}{4}$ resolution sub-pixel d is obtained by averaging values of its nearest horizontal neighbours, original image pixel A and $\frac{1}{2}$ resolution sub-pixel b. Similarly, a value for $\frac{1}{4}$ resolution

37

sub-pixel g is obtained by taking the average of its two nearest horizontal neighbours, $\frac{1}{2}$ resolution sub-pixels b and c.

Values for $\frac{1}{4}$ resolution sub-pixels labelled e, f and i are calculated from the values of their nearest neighbours in the vertical direction using linear interpolation. More specifically, a value for $\frac{1}{4}$ resolution sub-pixel e is obtained by averaging the values of its two nearest vertical neighbours, original image pixel A and $\frac{1}{2}$ resolution sub-pixel b. Similarly, a value for $\frac{1}{4}$ resolution sub-pixel f is obtained by taking the average of its two nearest vertical neighbours, $\frac{1}{2}$ resolution sub-pixels b and c. In an embodiment of the invention, a value for $\frac{1}{4}$ resolution sub-pixel i is obtained in manner identical to that just described in connection with $\frac{1}{4}$ resolution sub-pixel f. However, in an alternative embodiment of the invention, and in common with the H.26 test models TML5 and TML6 previously described, $\frac{1}{4}$ resolution sub-pixel i is determined using the values of the four closest original image pixels, according to $(A_1 + A_2 + A_3 + A_4)/4$.

It should also be noted that in all cases where an average involving pixel and/or sub-pixel values is determined, the average may be formed in any appropriate manner. For example, the value for $\frac{1}{4}$ resolution sub-pixel d can be defined as $d = (A + b)/2$ or as $d = (A + b + 1)/2$. The addition of 1 to the sum of values for pixel A and $\frac{1}{2}$ resolution sub-pixel b has the effect of causing any rounding or truncation operation subsequently applied to round or truncate the value for d to the next highest integer value. This is true for any sum of integer values and may be applied to any of the averaging operations performed according to the method of the invention in order to control rounding or truncation effects.

It should be noted that the sub-pixel value interpolation method according to the invention provides advantages over each of TML5 and TML6.

In contrast to TML5, in which the values of some of the $\frac{1}{4}$ resolution sub-pixels depend on previously interpolated values obtained for other $\frac{1}{4}$ resolution sub-pixels, in the method according to the invention, all $\frac{1}{4}$ resolution sub-pixels are calculated from original image pixels or $\frac{1}{2}$ resolution sub-pixel positions using linear interpolation. Thus, the reduction in precision of those $\frac{1}{4}$ resolution sub-pixel values which occurs in TML5 due to the intermediate truncation and clipping of the other $\frac{1}{4}$ resolution sub-pixels from which they are calculated, does not take place in the method according to the invention. In particular, referring to FIG. 14a, $\frac{1}{4}$ resolution sub-pixels h (and sub-pixel i in one embodiment of the invention) are interpolated diagonally in order to reduce dependency on other $\frac{1}{4}$ -pixels. Furthermore, in the method according to the invention, the number of calculations (and therefore the number of processor cycles) required to obtain a value for those $\frac{1}{4}$ resolution sub-pixels in the decoder is reduced compared with TML5. Additionally, the calculation of any $\frac{1}{4}$ resolution sub-pixel value requires a number of calculations which is substantially similar to the number of calculations required to determine any other $\frac{1}{4}$ resolution sub-pixel value. More specifically, in a situation where the required $\frac{1}{2}$ resolution sub-pixel values are already available, e.g. they have been calculated before-hand, the number of calculations required to interpolate a $\frac{1}{4}$ resolution sub-pixel value from the pre-calculated $\frac{1}{2}$ resolution sub-pixel values is the same as the number of calculations required to calculate any other $\frac{1}{4}$ resolution sub-pixel value from the available $\frac{1}{2}$ resolution sub-pixel values.

In comparison with TML6, the method according to the invention does not require high precision arithmetic to be

38

used in the calculation of all sub-pixels. Specifically, as all of the $\frac{1}{4}$ resolution sub-pixel values are calculated from original image pixels or $\frac{1}{2}$ resolution sub-pixel values using linear interpolation, lower precision arithmetic can be used in their interpolation. Consequently, in hardware implementations of the inventive method, for example in an ASIC (Application Specific Integrated Circuit), the use of lower precision arithmetic reduces the number of components (e.g. gates) that must be devoted to the calculation of $\frac{1}{4}$ resolution sub-pixel values. This, in turn, reduces the overall area of silicon that must be dedicated to the interpolation function. As the majority of sub-pixels are, in fact, $\frac{1}{4}$ resolution sub-pixels (12 out of the 15 sub-pixels illustrated in FIG. 14a), the advantage provided by the invention in this respect is particularly significant. In software implementations, where sub-pixel interpolation is performed using the standard instruction set of a general purpose CPU (Central Processor Unit) or using a DSP (Digital Signal Processor), a reduction in the precision of the arithmetic required generally leads to an increase in the speed at which the calculations can be performed. This is particularly advantageous in 'low cost' implementations, in which it is desirable to use a general purpose CPU rather than any form of ASIC.

The method according to the invention provides still further advantages compared with TML5. As mentioned previously, in the decoder only 1 out of the 15 sub-pixel positions is required at any given time, namely that which is indicated by received motion vector information. Therefore, it is advantageous if the value of a sub-pixel in any sub-pixel location can be calculated with the minimum number of steps that result in a correctly interpolated value. The method according to the invention provides this capability. As mentioned in the detailed description provided above, $\frac{1}{2}$ resolution sub-pixel c can be interpolated by filtering in either the vertical or the horizontal direction, the same value being obtained for c regardless of whether horizontal or vertical filtering is used. The decoder can therefore take advantage of this property when calculating values for $\frac{1}{4}$ resolution sub-pixels f and g in such a way as to minimise the number of operations required in order to obtain the required values. For example, if the decoder requires a value for $\frac{1}{4}$ resolution sub-pixel f, $\frac{1}{2}$ resolution sub-pixel c should be interpolated in the vertical direction. If a value is required for $\frac{1}{4}$ resolution sub-pixel g, it is advantageous to interpolate a value for c in the horizontal direction. Thus, in general, it can be said that the method according to the invention provides flexibility in the way in which values are derived for certain $\frac{1}{4}$ resolution sub-pixels. No such flexibility is provided in TML5.

Two specific embodiments will now be described in detail. The first represents a preferred embodiment for calculating sub-pixels with up to $\frac{1}{4}$ pixel resolution, while in the second, the method according to the invention is extended to the calculation of values for sub-pixels having up to $\frac{1}{8}$ pixel resolution. For both embodiments a comparison is provided between the computational complexity/burden resulting from use of the method according to the invention and that which would result from use of the interpolation methods according to TML5 and TML6 in equivalent circumstances.

The preferred embodiment for interpolating sub-pixels at $\frac{1}{4}$ pixel resolution will be described with reference to FIGS. 14a, 14b and 14c. In the following, it will be assumed that all image pixels and final interpolated values for sub-pixels are represented with 8-bits.

Calculation of $\frac{1}{2}$ resolution sub-pixels at i) half unit horizontal and unit vertical locations and ii) unit horizontal and half unit vertical locations.

1. A value for the sub-pixel at half unit horizontal and unit vertical location, that is $\frac{1}{2}$ resolution sub-pixel b in FIG. 14a, is obtained by first calculating intermediate value $b=(A_1-5A_2+20A_3+20A_4-5A_5+A_6)$ using the values of the six pixels (A_1 to A_6) which are situated at unit horizontal and unit vertical locations in either the row or the column of pixels containing b and which are disposed symmetrically about b, as shown in FIGS. 14b and 14c. A final value for $\frac{1}{2}$ resolution sub-pixel b is calculated as $(b+16)/32$ where the operator / denotes division with truncation. The result is clipped to lie in the range [0, 255].

Calculation of $\frac{1}{2}$ resolution sub-pixels at half unit horizontal and half unit vertical locations.

2. A value for the sub-pixel at half unit horizontal and half unit vertical location, that is $\frac{1}{2}$ resolution sub-pixel c in FIG. 14a, is calculated as $c=(b_1-5b_2+20b_3+20b_4-5b_5+b_6+512)/1024$ using the intermediate values b for the six closest $\frac{1}{2}$ resolution sub-pixels which are situated in either the row or the column of sub-pixels containing c and which are disposed symmetrically about c. Again, operator / denotes division with truncation and the result is clipped to lie in the range [0, 255]. As previously explained, using intermediate values b for $\frac{1}{2}$ resolution sub-pixels b in the horizontal direction leads to the same result as using intermediate values b for $\frac{1}{2}$ resolution sub-pixels b in the vertical direction. Thus, in an encoder according to the invention, the direction for interpolating $\frac{1}{2}$ resolution sub-pixels b can be chosen according to a preferred mode of implementation. In a decoder according to the invention, the direction for interpolating sub-pixels b is chosen according to which, if any, $\frac{1}{4}$ resolution sub-pixels will be interpolated using the result obtained for $\frac{1}{2}$ resolution sub-pixel c.

Calculation of $\frac{1}{4}$ resolution sub-pixels at i) quarter unit horizontal and unit vertical locations; ii) quarter unit horizontal and half unit vertical locations; iii) unit horizontal and quarter unit vertical locations; and iv) half unit horizontal and quarter unit vertical locations.

3. Values for $\frac{1}{4}$ resolution sub-pixels d, situated at quarter unit horizontal and unit vertical locations are calculated according to $d=(A+b)/2$ using the nearest original image pixel A and the closest $\frac{1}{2}$ resolution sub-pixel b in the horizontal direction. Similarly, values for $\frac{1}{4}$ resolution sub-pixels g, situated at quarter unit horizontal and half unit vertical locations are calculated according to $g=(b+c)/2$ using the two nearest $\frac{1}{2}$ resolution sub-pixels in the horizontal direction. In a similar manner, values for $\frac{1}{4}$ resolution sub-pixels e, situated at unit horizontal and quarter unit vertical locations, are calculated according to $e=(A+b)/2$ using the nearest original image pixel A and the closest $\frac{1}{2}$ resolution sub-pixel b in the vertical direction. Values for $\frac{1}{4}$ resolution sub-pixels f, situated at half unit horizontal and quarter unit vertical locations, are determined from $f=(b+c)/2$ using the two nearest $\frac{1}{2}$ resolution sub-pixel in the vertical direction. In all cases, operator / denotes division with truncation.

Calculation of $\frac{1}{4}$ resolution sub-pixels at quarter unit horizontal and quarter unit vertical locations.

4. Values for $\frac{1}{4}$ resolution sub-pixels h, situated at quarter unit horizontal and quarter unit vertical locations are calculated according to $h=(b_1+b_2)/2$, using the two nearest $\frac{1}{2}$ resolution sub-pixels b in the diagonal direction. Again, operator / denotes division with truncation.

5. A value for the $\frac{1}{4}$ resolution sub-pixel labeled i is computed from $i=(A_1+A_2+A_3+A_4+2)/4$ using the four nearest original pixels A. Once more, operator / denotes division with truncation.

An analysis of the computational complexity of the first preferred embodiment of the invention will now be presented.

In the encoder, it is likely that the same sub-pixel values will be calculated multiple times. Therefore, and as previously explained, the complexity of the encoder can be reduced by pre-calculating all sub-pixel values and storing them in memory. However, this solution increases memory usage by a large margin. In the preferred embodiment of the invention, in which motion vector accuracy is $\frac{1}{4}$ pixel resolution in both the horizontal and vertical dimensions, storing pre-calculated sub-pixel values for the whole image requires 16 times the memory required to store the original, non-interpolated image. To reduce memory usage, all $\frac{1}{2}$ resolution sub-pixels can be interpolated before-hand and $\frac{1}{4}$ resolution sub-pixels can be calculated on-demand, that is, only when they are needed. According to the method of the invention, on-demand interpolation of values for $\frac{1}{4}$ resolution sub-pixels only requires linear interpolation from $\frac{1}{2}$ resolution sub-pixels. Four times the original picture memory is required to store the pre-calculated $\frac{1}{2}$ resolution sub-pixels since only 8 bits are necessary to represent them.

However, if the same strategy of pre-calculating all $\frac{1}{2}$ resolution sub-pixels using before-hand interpolation is used in conjunction with the direct interpolation scheme of TML6, the memory requirements increase to 9 times the memory required to store the original non-interpolated image. This results from the fact that a larger number of bits is required to store the high precision intermediate values associated with each $\frac{1}{2}$ resolution sub-pixel in TML6. In addition, the complexity of sub-pixel interpolation during motion estimation is higher in TML6, since scaling and clipping has to be performed for every $\frac{1}{2}$ and $\frac{1}{4}$ sub-pixel location.

In the following, the complexity of the sub-pixel value interpolation method according to the invention, when applied in a video decoder, is compared with that of the interpolation schemes used in TML5 and TML6. Throughout the analysis which follows, it is assumed that in each method the interpolation of any sub-pixel value is performed using only the minimum number of steps required to obtain a correctly interpolated value. It is further assumed that each method is implemented in a block based manner, that is, intermediate values common for all the sub-pixels to be interpolated in a particular $N \times M$ block are calculated only once. An illustrative example is provided in FIG. 16. Referring to FIG. 16, it can be seen that in order to calculate a 4×4 block of $\frac{1}{2}$ resolution sub-pixels c, a 9×4 block of $\frac{1}{2}$ resolution sub-pixels b is first calculated.

Compared with the sub-pixel value interpolation method used in TML5, the method according to the invention has a lower computational complexity for the following reasons:

1. Unlike the sub-pixel value interpolation scheme used in TML5, according to the method of the invention, a value for $\frac{1}{2}$ resolution sub-pixel c can be obtained by filtering in either the vertical or the horizontal direction. Thus, in order to reduce the number of operations, $\frac{1}{2}$ resolution sub-pixel c can be interpolated in the vertical direction if a value for $\frac{1}{4}$ resolution sub-pixel f is required and in the horizontal direction if a value for $\frac{1}{4}$ resolution sub-pixel g is required. As an example, FIG. 17 shows all the $\frac{1}{2}$ resolution sub-pixel values that must be calculated in order to interpolate values for $\frac{1}{4}$ resolution sub-pixels g in

an image block defined by 4x4 original image pixels using the interpolation method of TML5 (FIG. 17a) and using the method according to the invention (FIG. 17b). In this example, the sub-pixel value interpolation method according to TML5 requires a total of 88½ resolution sub-pixels to be interpolated, while the method according to the invention requires the calculation of 72½ resolution sub-pixels. As can be seen from FIG. 17b, according to the invention, ½ resolution sub-pixels c are interpolated in the horizontal direction in order to reduce the number of calculations required.

2. According to the method of the invention, ¼ resolution sub-pixel h is calculated by linear interpolation from its two closest neighbouring ½ resolution sub-pixels in the diagonal direction. The respective numbers of ½ resolution sub-pixels that must be calculated in order to obtain values for ¼ resolution sub-pixels h within a 4x4 block of original image pixels using the sub-pixel value interpolation method according to TML5 and the method according to the invention are shown in FIGS. 18(a) and 18(b), respectively. Using the method according to TML5 it is necessary to interpolate a total of 56½ resolution sub-pixels, while according to the method of the invention it is necessary to interpolate 40½ resolution sub-pixels.

Table 1 summarizes the decoder complexities of the three sub-pixel value interpolation methods considered here, that according to TML5, the direct interpolation method used in TML6 and the method according to the invention. Complexity is measured in terms of the number of 6-tap filtering and linear interpolation operations performed. It is assumed that Interpolation of ¼ resolution sub-pixel i is calculated according to $i=(A_1+A_2+A_3+A_4+2)/4$ which is bilinear interpolation and effectively comprises two linear interpolation operations. The operations needed to interpolate sub-pixel values with one 4x4 block of original image pixels are listed for each of the 15 sub-pixel positions which, for convenience of reference, are numbered according to the scheme shown in FIG. 19. Referring to FIG. 19, location 1 is the location of an original image pixel A and locations 2 to 16 are sub-pixel locations. Location 16 is the location of ¼ resolution sub-pixel i. In order to compute the average number of operations it has been assumed that the probability of a motion vector pointing to each sub-pixel position is the same. The average complexity is therefore the average of the 15 sums calculated for each sub-pixel location and the single full-pixel location.

TABLE 1

Complexity of ¼ resolution sub-pixel interpolation in TML5, TML6 and the method according to the invention.						
Location	TML5		TML6		Inventive Method	
	linear.	6-tap	linear.	6-tap	linear.	6-tap

It can be seen from Table 1 that the method according to the invention requires fewer 6-tap filter operations than the sub-pixel value interpolation method according to TML6 and only a few additional linear interpolation operations.

Since 6-tap filter operations are much more complex than linear interpolation operations the complexity of the two methods is similar. The sub-pixel value interpolation method according to TML5 has a considerably higher complexity.

The preferred embodiment for interpolating sub-pixels with up to ⅛ pixel resolution will now be described with reference to FIGS. 20, 21 and 22.

FIG. 20 presents the nomenclature used to describe pixels, ½ resolution sub-pixels, ¼ resolution sub-pixels and ⅛ resolution sub-pixels in this extended application of the method according to the invention.

1. Values for the ½ resolution and ¼ resolution sub-pixels labelled b^1 , b^2 and b^3 in FIG. 20 are obtained by first calculating intermediate values $b^1=(-3A_1+12A_2-37A_3+229A_4+71A_5-21A_6+6A_7-A_8)$; $b^2=(-3A_1+12A_2-39A_3+158A_4+158A_5-39A_6+12A_7-3A_8)$; and $b^3=(-A_1+6A_2-21A_3+71A_4+229A_5-37A_6+13A_7-3A_8)$ using the values of the eight nearest image pixels (A_1 to A_8) situated at unit horizontal and unit vertical locations in either the row or the column containing b^1 , b^2 and b^3 and disposed symmetrically about ½ resolution sub-pixel b^2 . The asymmetries in the filter coefficients used to obtain intermediate values b^1 and b^3 account for the fact that pixels A_1 to A_8 are not symmetrically located with respect to ¼ resolution sub-pixels b^1 and b^3 . Final values for sub-pixels b^i , $i=1, 2, 3$ are calculated according to $b^i=(b^i+128)/256$ where the operator / denotes division with truncation. The result is clipped to lie in the range [0, 255].

2. Values for the ½ resolution and ¼ resolution sub-pixels labelled c^{ij} , $i, j=1, 2, 3$, are calculated according to $c^{1j}=(-3b_1^j+12b_2^j-37b_3^j+229b_4^j+71b_5^j-21b_6^j+6b_7^j-b_8^j+32768)/65536$, $c^{2j}=(-3b_1^j+12b_2^j-39b_3^j+158b_4^j+158b_5^j-39b_6^j+12b_7^j-3b_8^j+32768)/65536$ and $c^{3j}=(-b_1^j+6b_2^j-21b_3^j+71b_4^j+229b_5^j-37b_6^j+13b_7^j-3b_8^j+32768)/65536$ using the intermediate values b^1 , b^2 and b^3 calculated for the eight closest sub-pixels (b_1^j to b_8^j) in the vertical direction, sub-pixels b^j being situated in the column comprising the ½ resolution and ¼ resolution sub-pixels c^{ij} being interpolated and disposed symmetrically about the ½ resolution sub-pixel c^{2j} . The asymmetries in the filter coefficients used to obtain values for sub-pixels c^{1j} and c^{3j} account for the fact that sub-pixels b_1^j to b_8^j are not symmetrically located with respect to ¼ resolution sub-pixels c^{1j} and c^{3j} . Once more, operator / denotes division with truncation. Before the interpolated values for sub-pixels c^{ij} are stored in the frame memory they are clipped to lie in the range [0, 255]. In an alternative embodiment of the invention, ½ resolution and ¼ resolution sub-pixels c^{ij} are calculated using in an analogous manner using intermediate values b^1 , b^2 and b^3 in the horizontal direction.

3. Values for ⅛ resolution sub-pixels labelled d are calculated using linear interpolation from the values of their closest neighbouring image pixel, ½ resolution or ¼ resolution sub-pixels in the horizontal or vertical direction. For example, upper leftmost ⅛ resolution sub-pixel d is calculated according to $d=(A+b^1+1)/2$. As before, operator / indicates division with truncation.

4. Values for ⅛ resolution sub-pixels labelled e and f are calculated using linear interpolation from the values of image pixels, ½ resolution or ¼ resolution sub-pixels in the diagonal direction. For example, referring to FIG. 20, upper leftmost pixel ⅛ resolution sub-pixel e is calculated according to $e=(b^1+b^1+1)/2$. The diagonal direction to be used in the interpolation of each ⅛ resolution sub-pixel in a first preferred embodiment of the invention, hereinafter referred to as 'preferred method 1', is indicated in FIG.

21(a). Values for $\frac{1}{8}$ resolution sub-pixels labelled g are calculated according to $g=(A+3c^{22}+3)/4$. As always, operator / denotes division with truncation. In an alternative embodiment of the invention, hereinafter referred to as 'preferred method 2', computational complexity is further reduced by interpolating $\frac{1}{8}$ resolution sub-pixels f using linear interpolation from $\frac{1}{2}$ resolution sub-pixels b^2 , that is, according to the relationship $f=(3b^2+b^2+2)/4$. The b^2 sub-pixel which is closer to f is multiplied by 3. The diagonal interpolation scheme used in this alternative embodiment of the invention is depicted in FIG. 21(b). In further alternative embodiments, different diagonal interpolation schemes can be envisaged.

It should be noted that in all cases where an average involving pixel and/or sub-pixel values is used in the determination of $\frac{1}{8}$ resolution sub-pixels, the average may be formed in any appropriate manner. The addition of 1 to the sum of values used in calculating such an average has the effect of causing any rounding or truncation operation subsequently applied to round or truncate the average in question to the next highest integer value. In alternative embodiments of the invention, the addition of 1 is not used.

As in the case of sub-pixel value interpolation to $\frac{1}{4}$ pixel resolution previously described, memory requirements in the encoder can be reduced by pre-calculating only a part of the sub-pixel values to be interpolated. In the case of sub-pixel value interpolation to $\frac{1}{8}$ pixel resolution, it is advantageous to calculate all $\frac{1}{2}$ resolution and $\frac{1}{4}$ resolution

at up to $\frac{1}{8}$ pixel resolution, is compared with that of the interpolation schemes used in TML5 and TML6. As in the equivalent analysis for $\frac{1}{4}$ pixel resolution sub-pixel value interpolation described above, it is assumed that in each method the interpolation of any sub-pixel value is performed using only the minimum number of steps required to obtain a correctly interpolated value. It is also assumed that each method is implemented in a block based manner, such that intermediate values common for all the sub-pixels to be interpolated in a particular N×M block are calculated only once.

Table 2 summarizes complexities of the three interpolation methods. Complexity is measured in terms of the number of 8-tap filter and linear interpolation operations performed in each method. The table presents the number of operations required to interpolate each of the $63\frac{1}{8}$ resolution sub-pixels within one 4×4 block of original image pixels, each sub-pixel location being identified with a corresponding number, as illustrated in FIG. 22. In FIG. 22, location 1 is the location of an original image pixel and locations 2 to 64 are sub-pixel locations. When computing the average number of operations, it has been assumed that the probability of a motion vector pointing to each sub-pixel position is the same. The average complexity is thus the average of the 63 sums calculated for each sub-pixel location and the single full-pixel location.

TABLE 2

Complexity of $\frac{1}{8}$ resolution sub-pixel interpolation in TML5, TML6 and the method according to the invention. (Results shown separately for Preferred Method 1 and Preferred Method 2).

sub-pixels before-hand and to compute values for $\frac{1}{8}$ resolution sub-pixels in an on-demand fashion, only when they are required. When this approach is taken, both the interpolation method according to TML5 and that according to the invention require 16 times the original picture memory to store the $\frac{1}{2}$ resolution and $\frac{1}{4}$ resolution sub-pixel values. However, if the direct interpolation method according to TML6 is used in the same way, intermediate values for the $\frac{1}{2}$ resolution and $\frac{1}{4}$ pixel resolution sub-pixels must be stored. These intermediate values are represented with 32-bit precision and this results in a memory requirement 64 times that for the original, non-interpolated image.

In the following, the complexity of the sub-pixel value interpolation method according to the invention, when applied in a video decoder to calculate values for sub-pixels

As can be seen from Table 2, the number of 8-tap filtering operations performed according to preferred methods 1 and 2 are, respectively, 26% and 34% lower than the number of 8-tap filtering operation performed in the sub-pixel value interpolation method of TML5. The number of linear operations is 25% lower, in both preferred method 1 and preferred method 2, compared with TML5, but this improvement is of lesser importance compared to the reduction in 8-tap filtering operations. It can further be seen that the direct interpolation method used in TML6 has a complexity comparable that of both preferred methods 1 and 2 when used to interpolate values for $\frac{1}{8}$ resolution sub-pixels.

In view of the foregoing description it will be evident to a person skilled in the art that various modifications may be made within the scope of the invention. While a number of

preferred embodiments of the invention have been described in detail, it should be apparent that many modifications and variations thereto are possible, all of which fall within the true spirit and scope of the invention.

What is claimed is:

1. A method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the method comprising:

- a) when values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
 - b) when values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations are required, interpolating such values directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and
 - c) when a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location is required, interpolating such a value by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location.
2. A method according to claim 1 wherein a first and a second weight are used in the weighted average referred to in (c), the relative magnitudes of the weights being inversely proportional to the (straight-line diagonal) proximity of the first and the second sub-pixel or pixel to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location.

3. A method according to claim 2, wherein in a situation where the first and the second sub-pixel or pixel are symmetrically located with respect to (equidistant from) the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location, the first and second weights have equal values.

4. A method according to claim 1 in which the first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations in step b) is used when a sub-pixel at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^N$ unit vertical location is required.

5. A method according to claim 1 in which the second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations in step b) is used when a sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location is required.

6. A method according to claim 1 in which, when values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and unit vertical locations, and $\frac{1}{2}^N$ horizontal and $\frac{1}{2}^{N-1}$ vertical locations are required, interpolating such values by taking the average of the values of a first pixel or sub-pixel located at a vertical location corresponding to that of the sub-pixel being calcu-

lated and unit horizontal location and a second pixel or sub-pixel located at a vertical location corresponding to that of the sub-pixel being calculated and $\frac{1}{2}^{N-1}$ unit horizontal location.

7. A method according to claim 1 in which, when values for sub-pixels at unit horizontal and $\frac{1}{2}^N$ unit vertical locations, and $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are required, interpolating such values by taking the average of the values of a first pixel or sub-pixel located at a horizontal location corresponding to that of the sub-pixel being calculated and unit vertical location and a second pixel or sub-pixel located at a horizontal location corresponding to that of the sub-pixel being calculated and $\frac{1}{2}^{N-1}$ unit vertical location.

8. A method according to claim 1 in which values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are interpolated by taking the average of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

9. A method according to claim 1 in which values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are interpolated by taking the average of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

10. A method according to claim 1 in which values for half of the sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are interpolated by taking the average of a first pair of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location and values for the other half of the sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are interpolated by taking the average of a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

11. A method according to claim 10 in which values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are alternately interpolated for one such sub-pixel by taking the average of a first pair of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location and values and for a neighbouring such sub-pixel by taking the average of a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

12. A method according to claim 11 in which the sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are alternately interpolated in a horizontal direction.

13. A method according to claim 11 in which the sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are alternately interpolated in a vertical direction.

14. A method according to claim 1 in which when values for some sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations are required, such values are interpolated by taking the average of a plurality of nearest neighbouring pixels.

15. A method according to claim 1 in which N equals an integer selected from a list consisting of the values 2, 3, and 4.

16. A method according to claim 1 in which in at least one of step a) and step b) interpolating sub-pixel values directly using weighted sums involves the calculation of an intermediate value for the sub-pixel values having a dynamic range greater than the specified dynamic range.

17. A method according to claim 14 in which the intermediate value for a sub-pixel having $\frac{1}{2}^{N-1}$ sub-pixel resolution is used the calculation of a sub-pixel value having $\frac{1}{2}^N$ sub-pixel resolution.

18. A method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the method comprising:

- a) when values for sub-pixels at half unit horizontal and unit vertical locations, and unit horizontal and half unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) when values for sub-pixels at half unit horizontal and half unit vertical locations are required, interpolating such values directly using a weighted sum of values for sub-pixels residing at half unit horizontal and unit vertical locations calculated according to step (a); and
- c) when values for sub-pixels at quarter unit horizontal and quarter unit vertical locations are required, interpolating such values by taking the average of at least one pair of a first pair of values of a sub-pixel located at a half unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and half unit vertical location and a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a half unit horizontal and half unit vertical location.

19. A method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$ where x is a positive integer having a maximum value N, the method comprising:

- a) when values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) when a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required, interpolating such a value directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

20. A method according to claim 1 in which the sub-pixels used in the first weighted sum are sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and the first weighted sum is used to interpolate a value for a sub-pixel at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^N$ unit vertical location.

21. A method according to claim 1 in which the sub-pixels used in the second weighted sum are sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations and the second weighted sum is used to interpolate a value for a sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

22. A method according to claim 1 in which when values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical

locations are required, they are interpolated by taking the average of at least one pair of a first pair of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location and a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

23. A video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the video coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the interpolator being adapted to:

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and
- c) interpolate a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

24. A video coder according to claim 23, comprising a video encoder.

25. A video encoder according to claim 23, comprising a video decoder.

26. A codec comprising the video encoder of claim 24 or the video decoder of claim 25.

27. A communications terminal comprising a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the video coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the interpolator being adapted to:

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using a choice

of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and

- c) interpolate a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

28. A communications terminal according to claim 27 comprising a video encoder.

29. A communications terminal according to claim 27 comprising a video decoder.

30. A communications terminal according to claim 27 having a video codec comprising a video encoder and a video decoder.

31. A telecommunications system comprising a communications terminal and a network, the telecommunications network and the communications terminal being connected by a communications link over which coded video can be transmitted, the communications terminal comprising a video coder for coding for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the video coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the interpolator being adapted to:

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and
- c) interpolate a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

32. A telecommunications system according to claim 31 which is a mobile telecommunications system comprising a mobile communications terminal and a wireless network, the connection between the mobile communications terminal and the wireless network being formed by a radio link.

33. A telecommunications system according to claim 31 in which the network enables the communications terminal to communicate with other communications terminals connected to the network over communications links between the other communications terminals and the network.

34. A telecommunications system comprising a communications terminal and a network, the telecommunications network and the communications terminal being connected by a communications link over which coded video can be transmitted, the network comprising a video coder for coding for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the video coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the interpolator being adapted to:

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and
- c) interpolate a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.

35. A video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the resolution of the sub-pixels being determined by a positive integer N, the interpolator being adapted to:

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

51

36. A video coder according to claim 35 in which the interpolator is further adapted to form the first weighted sum using the values of sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and to use the first weighted sum to interpolate a value for a sub-pixel at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^N$ unit vertical location.

37. A video coder according to claim 35 in which the interpolator is further adapted to form the second weighted sum using the values of sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations and to use the second weighted sum to interpolate a value for a sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

38. A video coder according to claim 35 in which the interpolator is further adapted to interpolate values for sub-pixels at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical locations by taking the average of at least one pair of a first pair of values of a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location and a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical location.

39. A video coder according to claim 35, comprising a video encoder.

40. A video decoder according to claim 35, comprising a video decoder.

41. A codec comprising the video encoder of claim 39 or the video decoder of claim 40.

42. A communications terminal comprising a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the resolution of the sub-pixels being determined by a positive integer N, the interpolator being adapted to:

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

43. A communications terminal according to claim 42 comprising a video encoder.

44. A communications terminal according to claim 42 comprising a video decoder.

45. A communications terminal according to claim 42 having a video codec comprising a video encoder and a video decoder.

46. A telecommunications system comprising a communications terminal and a network, the telecommunications network and the communications terminal being connected by a communications link over which coded video can be transmitted, the communications terminal comprising a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns

52

residing at unit vertical locations, the coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the resolution of the sub-pixels being determined by a positive integer N, the interpolator being adapted to:

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

47. A telecommunications system according to claim 46 which is a mobile telecommunications system comprising a mobile communications terminal and a wireless network, the connection between the mobile communications terminal and the wireless network being formed by a radio link.

48. A telecommunications system according to claim 46 in which the network enables the communications terminal to communicate with other communications terminals connected to the network over communications links between the other communications terminals and the network.

49. A telecommunications system comprising a communications terminal and a network, the telecommunications network and the communications terminal being connected by a communications link over which coded video can be transmitted, the network comprising a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the resolution of the sub-pixels being determined by a positive integer N, the interpolator being adapted to:

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

50. A codec for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the codec comprising a video encoder and a video decoder, each of the video encoder and the video decoder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $\frac{1}{2}^x$, where x is a positive integer having a maximum value N, the interpolator of the video encoder and the interpolator of the video decoder each being adapted to:

53

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
 - b) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using a choice of a first weighted sum of values for sub-pixels residing at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and
 - c) interpolate a value for a sub-pixel situated at a $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $\frac{1}{2}^{N-m}$ unit horizontal and $\frac{1}{2}^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $\frac{1}{2}^{N-p}$ unit horizontal and $\frac{1}{2}^{N-q}$ unit vertical location, variables m, n, p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $\frac{1}{2}^N$ unit horizontal and $\frac{1}{2}^N$ vertical location.
51. A codec for coding an image comprising pixels arranged in rows and columns and represented by values

54

having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the codec comprising a video encoder and a video decoder, each of the video encoder and the video decoder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the resolution of the sub-pixels being determined by a positive integer N, the interpolator of the video encoder and the interpolator of the video decoder each being adapted to:

- a) interpolate values for sub-pixels at $\frac{1}{2}^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $\frac{1}{2}^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

METHOD FOR SUB-PIXEL VALUE INTERPOLATION

CROSS REFERENCE TO RELATED APPLICATIONS

This application is a continuation of, and claims priority to, U.S. application Ser. No. 09/954,608, filed on Sep. 17, 2001, now U.S. Pat. No. 6,950,469.

The present invention relates to a method for sub-pixel value interpolation in the encoding and decoding of data. It relates particularly, but not exclusively, to encoding and decoding of digital video.

BACKGROUND OF THE INVENTION

Digital video sequences, like ordinary motion pictures recorded on film, comprise a sequence of still images, the illusion of motion being created by displaying the images one after the other at a relatively fast frame rate, typically 15 to 30 frames per second. Because of the relatively fast frame rate, images in consecutive frames tend to be quite similar and thus contain a considerable amount of redundant information. For example, a typical scene may comprise some stationary elements, such as background scenery, and some moving areas, which may take many different forms, for example the face of a newsreader, moving traffic and so on. Alternatively, the camera recording the scene may itself be moving, in which case all elements of the image have the same kind of motion. In many cases, this means that the overall change between one video frame and the next is rather small. Of course, this depends on the nature of the movement. For example, the faster the movement, the greater the change from one frame to the next. Similarly, if a scene contains a number of moving elements, the change from one frame to the next is likely to be greater than in a scene where only one element is moving.

It should be appreciated that each frame of a raw, that is uncompressed, digital video sequence comprises a very large amount of image information. Each frame of an uncompressed digital video sequence is formed from an array of image pixels. For example, in a commonly used digital video format, known as the Quarter Common Interchange Format (QCIF), a frame comprises an array of 176×144 pixels, in which case each frame has 25,344 pixels. In turn, each pixel is represented by a certain number of bits, which carry information about the luminance and/or colour content of the region of the image corresponding to the pixel. Commonly, a so-called YUV colour model is used to represent the luminance and chrominance content of the image. The luminance, or Y, component represents the intensity (brightness) of the image, while the colour content of the image is represented by two chrominance components, labelled U and V.

Colour models based on a luminance/chrominance representation of image content provide certain advantages compared with colour models that are based on a representation involving primary colours (that is Red, Green and Blue, RGB). The human visual system is more sensitive to intensity variations than it is to colour variations; YUV colour models exploit this property by using a lower spatial resolution for the chrominance components (U, V) than for the luminance component (Y). In this way the amount of information needed to code the colour information in an image can be reduced with an acceptable reduction in image quality.

2

The lower spatial resolution of the chrominance components is usually attained by sub-sampling. Typically, a block of 16×16 image pixels is represented by one block of 16×16 pixels comprising luminance information and the corresponding chrominance components are each represented by one block of 8×8 pixels representing an area of the image equivalent to that of the 16×16 pixels of the luminance component. The chrominance components are thus spatially sub-sampled by a factor of 2 in the x and y directions. The resulting assembly of one 16×16 pixel luminance block and two 8×8 pixel chrominance blocks is commonly referred to as a YUV macroblock, or macroblock, for short.

A QCIF image comprises 11×9 macroblocks. If the luminance blocks and chrominance blocks are represented with 8 bit resolution (that is by numbers in the range 0 to 255), the total number of bits required per macroblock is $(16 \times 16 \times 8) + 2 \times (8 \times 8 \times 8) = 3072$ bits. The number of bits needed to represent a video frame in QCIF format is thus $99 \times 3072 = 304,128$ bits. This means that the amount of data required to transmit record/display a video sequence in QCIF format, represented using a YUV colour model, at a rate of 30 frames per second, is more than 9 Mbps (million bits per second). This is an extremely high data rate and is impractical for use in video recording, transmission and display applications because of the very large storage capacity, transmission channel capacity and hardware performance required.

If video data is to be transmitted in real-time over a fixed line network such as an ISDN (Integrated Services Digital Network) or a conventional PSTN (Public Service Telephone Network), the available data transmission bandwidth is typically of the order of 64 kbits/s. In mobile videotelephony, where transmission takes place at least in part over a radio communications link, the available bandwidth can be as low as 20 kbits/s. This means that a significant reduction in the amount of information used to represent video data must be achieved in order to enable transmission of digital video sequences over low bandwidth communication networks. For this reason video compression techniques have been developed which reduce the amount of information transmitted while retaining an acceptable image quality.

Video compression methods are based on reducing the redundant and perceptually irrelevant parts of video sequences. The redundancy in video sequences can be categorised into spatial, temporal and spectral redundancy. 'Spatial redundancy' is the term used to describe the correlation between neighbouring pixels within a frame. The term 'temporal redundancy' expresses the fact that the objects appearing in one frame of a sequence are likely to appear in subsequent frames, while 'spectral redundancy' refers to the correlation between different colour components of the same image.

Sufficiently efficient compression cannot usually be achieved by simply reducing the various forms of redundancy in a given sequence of images. Thus, most current video encoders also reduce the quality of those parts of the video sequence which are subjectively the least important. In addition, the redundancy of the compressed video bit-stream is itself reduced by means of efficient loss-less encoding. Typically, this is achieved using a technique known as 'variable length coding' (VLC).

Modern video compression standards, such as ITU-T recommendations H.261, H.263(+)(++), H.26L and the Motion Picture Experts Group recommendation MPEG-4 make use of 'motion compensated temporal prediction'. This is a form of temporal redundancy reduction in which the content of some (often many) frames in a video sequence

is 'predicted' from other frames in the sequence by tracing the motion of objects or regions of an image between frames.

Compressed images which do not make use of temporal redundancy reduction are usually called INTRA-coded or I-frames, whereas temporally predicted images are called INTER-coded or P-frames. In the case of INTER frames, the predicted (motion-compensated) image is rarely precise enough to represent the image content with sufficient quality, and therefore a spatially compressed prediction error (PE) frame is also associated with each INTER frame. Many video compression schemes can also make use of bi-directionally predicted frames, which are commonly referred to as B-pictures or B-frames. B-pictures are inserted between reference or so-called 'anchor' picture pairs (I or P frames) and are predicted from either one or both of the anchor pictures. B-pictures are not themselves used as anchor pictures, that is no other frames are predicted from them, and therefore, they can be discarded from the video sequence without causing deterioration in the quality of future pictures.

The different types of frame that occur in a typical compressed video sequence are illustrated in FIG. 3 of the accompanying drawings. As can be seen from the figure, the sequence starts with an INTRA or I frame 30. In FIG. 3, arrows 33 denote the 'forward' prediction process by which P-frames (labelled 34) are formed. The bidirectional prediction process by which B-frames (36) are formed is denoted by arrows 31a and 31b, respectively.

A schematic diagram of an example video coding system using motion compensated prediction is shown in FIGS. 1 and 2. FIG. 1 illustrates an encoder 10 employing motion compensation and FIG. 2 illustrates a corresponding decoder 20. The encoder 10 shown in FIG. 1 comprises a Motion Field Estimation block 11, a Motion Field Coding block 12, a Motion Compensated Prediction block 13, a Prediction Error Coding block 14, a Prediction Error Decoding block 15, a Multiplexing block 16, a Frame Memory 17, and an adder 19. The decoder 20 comprises a Motion Compensated Prediction block 21, a Prediction Error Decoding block 22, a Demultiplexing block 23 and a Frame Memory 24.

The operating principle of video coders using motion compensation is to minimise the amount of information in a prediction error frame $E_n(x,y)$, which is the difference between a current frame $I_n(x,y)$ being coded and a prediction frame $P_n(x,y)$. The prediction error frame is thus:

$$E_n(x,y) = I_n(x,y) - P_n(x,y). \quad (1)$$

The prediction frame $P_n(x,y)$ is built using pixel values of a reference frame $R_n(x,y)$, which is generally one of the previously coded and transmitted frames, for example the frame immediately preceding the current frame and is available from the Frame Memory 17 of the encoder 10. More specifically, the prediction frame $P_n(x,y)$ is constructed by finding so-called 'prediction pixels' in the reference frame $R_n(x,y)$ which correspond substantially with pixels in the current frame. Motion information, describing the relationship (e.g. relative location, rotation, scale etc.) between pixels in the current frame and their corresponding prediction pixels in the reference frame is derived and the prediction frame is constructed by moving the prediction pixels according to the motion information. In this way, the prediction frame is constructed as an approximate representation of the current frame, using pixel values in the reference frame. The prediction error frame referred to above therefore represents the difference between the approximate representation of the current frame provided by the prediction frame

and the current frame itself. The basic advantage provided by video encoders that use motion compensated prediction arises from the fact that a comparatively compact description of the current frame can be obtained by representing it in terms of the motion information required to form its prediction together with the associated prediction error information in the prediction error frame.

However, due to the very large number of pixels in a frame, it is generally not efficient to transmit separate motion information for each pixel to the decoder. Instead, in most video coding schemes, the current frame is divided into larger image segments S_k and motion information relating to the segments is transmitted to the decoder. For example, motion information is typically provided for each macroblock of a frame and the same motion information is then used for all pixels within the macroblock. In some video coding standards, such as H.26L, a macroblock can be divided into smaller blocks, each smaller block being provided with its own motion information.

The motion information usually takes the form of motion vectors $[\Delta x(x,y), \Delta y(x,y)]$. The pair of numbers $\Delta x(x,y)$ and $\Delta y(x,y)$ represents the horizontal and vertical displacements of a pixel at location (x,y) in the current frame $I_n(x,y)$ with respect to a pixel in the reference frame $R_n(x,y)$. The motion vectors $[\Delta x(x,y), \Delta y(x,y)]$ are calculated in the Motion Field Estimation block 11 and the set of motion vectors of the current frame $[\Delta x(\cdot), \Delta y(\cdot)]$ is referred to as the motion vector field.

Typically, the location of a macroblock in a current video frame is specified by the (x,y) co-ordinate of its upper left-hand corner. Thus, in a video coding scheme in which motion information is associated with each macroblock of a frame, each motion vector describes the horizontal and vertical displacement $\Delta x(x,y)$ and $\Delta y(x,y)$ of a pixel representing the upper left-hand corner of a macroblock in the current frame $I_n(x,y)$ with respect to a pixel in the upper left-hand corner of a substantially corresponding block of prediction pixels in the reference frame $R_n(x,y)$ (as shown in FIG. 4b).

Motion estimation is a computationally intensive task. Given a reference frame $R_n(x,y)$ and, for example, a square macroblock comprising $N \times N$ pixels in a current frame (as shown in FIG. 4a), the objective of motion estimation is to find an $N \times N$ pixel block in the reference frame that matches the characteristics of the macroblock in the current picture according to some criterion. This criterion can be, for example, a sum of absolute differences (SAD) between the pixels of the macroblock in the current frame and the block of pixels in the reference frame with which it is compared. This process is known generally as 'block matching'. It should be noted that, in general, the geometry of the block to be matched and that in the reference frame do not have to be the same, as real-world objects can undergo scale changes, as well as rotation and warping. However, in current international video coding standards, only a translational motion model is used (see below) and thus fixed rectangular geometry is sufficient.

Ideally, in order to achieve the best chance of finding a match, the whole of the reference frame should be searched. However, this is impractical as it imposes too high a computational burden on the video encoder. Instead, the search region is restricted to region $[-p, p]$ around the original location of the macroblock in the current frame, as shown in FIG. 4c.

In order to reduce the amount of motion information to be transmitted from the encoder 10 to the decoder 20, the motion vector field is coded in the Motion Field Coding

5

block 12 of the encoder 10, by representing it with a motion model. In this process, the motion vectors of image segments are re-expressed using certain predetermined functions or, in other words, the motion vector field is represented with a model. Almost all currently used motion vector field models are additive motion models, complying with the following general formula:

$$\Delta x(x, y) = \sum_{i=0}^{N-1} a_i f_i(x, y) \quad (2)$$

$$\Delta y(x, y) = \sum_{i=0}^{M-1} b_i g_i(x, y) \quad (3)$$

where coefficients a_i and b_i are called motion coefficients. The motion coefficients are transmitted to the decoder 20 (information stream 2 in FIGS. 1 and 2). Functions f_i and g_i are called motion field basis functions, and are known both to the encoder and decoder. An approximate motion vector field ($\Delta x(x, y), \Delta y(x, y)$) can be constructed using the coefficients and the basis functions. As the basis functions are known to (that is stored in) both the encoder 10 and the decoder 20, only the motion coefficients need to be transmitted to the encoder, thus reducing the amount of information required to represent the motion information of the frame.

The simplest motion model is the translational motion model which requires only two coefficients to describe the motion vectors of each segment. The values of motion vectors are given by:

$$\begin{aligned} \Delta x(x, y) &= a_0 \\ \Delta y(x, y) &= b_0 \end{aligned} \quad (4)$$

This model is widely used in various international standards (ISO MPEG-1, MPEG-2, MPEG4, ITU-T Recommendations H.261 and H.263) to describe the motion of 16x16 and 8x8 pixel blocks. Systems which use a translational motion model typically perform motion estimation at full pixel resolution or some integer fraction of full pixel resolution, for example at half or one quarter pixel resolution.

The prediction frame $P_n(x, y)$ is constructed in the Motion Compensated Prediction block 13 in the encoder 10, and is given by:

$$P_n(x, y) = R_n[x + \Delta x(x, y), y + \Delta y(x, y)] \quad (5)$$

In the Prediction Error Coding block 14, the prediction error frame $E_n(x, y)$ is typically compressed by representing it as a finite series (transform) of some 2-dimensional functions. For example, a 2-dimensional Discrete Cosine Transform (DCT) can be used. The transform coefficients are quantised and entropy (for example Huffman) coded before they are transmitted to the decoder (information stream 1 in FIGS. 1 and 2). Because of the error introduced by quantisation, this operation usually produces some degradation (loss of information) in the prediction error frame $E_n(x, y)$. To compensate for this degradation, the encoder 10 also comprises a Prediction Error Decoding block 15, where a decoded prediction error frame $\tilde{E}_n(x, y)$ is constructed using the transform coefficients. This locally decoded prediction error frame is added to the prediction frame $P_n(x, y)$ in the adder 19 and the resulting decoded current frame $\tilde{I}_n(x, y)$ is stored in the Frame Memory 17 for further use as the next reference frame $R_{n+1}(x, y)$.

6

The information stream 2 carrying information about the motion vectors is combined with information about the prediction error in multiplexer 16 and an information stream 3 containing typically at least those two types of information is sent to the decoder 20.

The operation of a corresponding video decoder 20 will now be described.

The Frame Memory 24 of the decoder 20 stores a previously reconstructed reference frame $R_n(x, y)$. The prediction frame $P_n(x, y)$ is constructed in the Motion Compensated Prediction block 21 of the decoder 20 according to equation 5, using received motion coefficient information and pixel values of the previously reconstructed reference frame $R_n(x, y)$. The transmitted transform coefficients of the prediction error frame $E_n(x, y)$ are used in the Prediction Error Decoding block 22 to construct the decoded prediction error frame $\tilde{E}_n(x, y)$. The pixels of the decoded current frame $\tilde{I}_n(x, y)$ are then reconstructed by adding the prediction frame $P_n(x, y)$ and the decoded prediction error frame $\tilde{E}_n(x, y)$:

$$\tilde{I}_n(x, y) = P_n(x, y) + \tilde{E}_n(x, y) = R_n[x + \Delta x(x, y), y + \Delta y(x, y)] + \tilde{E}_n(x, y). \quad (6)$$

This decoded current frame may be stored in the Frame Memory 24 as the next reference frame $R_{n+1}(x, y)$.

In the description of motion compensated encoding and decoding of digital video presented above, the motion vector $[\Delta x(x, y), \Delta y(x, y)]$ describing the motion of a macroblock in the current frame with respect to the reference frame $R_n(x, y)$ can point to any of the pixels in the reference frame. This means that motion between frames of a digital video sequence can only be represented at a resolution which is determined by the image pixels in the frame (so-called full pixel resolution). Real motion, however, has arbitrary precision, and thus the system described above can only provide approximate modelling of the motion between successive frames of a digital video sequence. Typically, modelling of motion between video frames with full pixel resolution is not sufficiently accurate to allow efficient minimisation of the prediction error (PE) information associated with each macroblock/frame. Therefore, to enable more accurate modelling of real motion and to help reduce the amount of PE information that must be transmitted from encoder to decoder, many video coding standards, such as H.263(+) and H.26L, allow motion vectors to point 'in between' image pixels. In other words, the motion vectors can have 'sub-pixel' resolution. Allowing motion vectors to have sub-pixel resolution adds to the complexity of the encoding and decoding operations that must be performed, so it is still advantageous to limit the degree of spatial resolution a motion vector may have. Thus, video coding standards, such as those previously mentioned, typically only allow motion vectors to have full-, half- or quarter-pixel resolution.

Motion estimation with sub-pixel resolution is usually performed as a two-stage process, as illustrated in FIG. 5, for a video coding scheme which allows motion vectors to have full- or half-pixel resolution. In the first step, a motion vector having full-pixel resolution is determined using any appropriate motion estimation scheme, such as the block-matching process described in the foregoing. The resulting motion vector, having full-pixel resolution is shown in FIG. 5.

In the second stage, the motion vector determined in the first stage is refined to obtain the desired half-pixel resolution. In the example illustrated in FIG. 5, this is done by forming eight new search blocks of 16x16 pixels, the location of the top-left corner of each block being marked with an X in FIG. 5. These locations are denoted as $[\Delta x + m/2, \Delta y + n/2]$, where m and n can take the values -1, 0

and +1, but cannot be zero at the same time. As only the pixel values of original image pixels are known, the values (for example luminance and/or chrominance values) of the sub-pixels residing at half-pixel locations must be estimated for each of the eight new search blocks, using some form of interpolation scheme.

Having interpolated the values of the sub-pixels at half-pixel resolution, each of the eight search blocks is compared with the macroblock whose motion vector is being sought. As in the block matching process performed in order to determine the motion vector with full pixel resolution, the macroblock is compared with each of the eight search blocks according to some criterion, for example a SAD. As a result of the comparisons, a minimum SAD value will generally be obtained. Depending on the nature of the motion in the video sequence, this minimum value may correspond to the location specified by the original motion vector (having full-pixel resolution), or it may correspond to a location having a half-pixel resolution. Thus, it is possible to determine whether a motion vector should point to a full-pixel or sub-pixel location and if sub-pixel resolution is appropriate, to determine the correct sub-pixel resolution motion vector. It should also be appreciated that the scheme just described can be extended to other sub-pixel resolutions (for example, one-quarter-pixel resolution) in an entirely analogous fashion.

In practice, the estimation of a sub-pixel value in the reference frame is performed by interpolating the value of the sub-pixel from surrounding pixel values. In general, interpolation of a sub-pixel value $F(x,y)$ situated at a non-integer location $(x, y) = (n + \Delta x, m + \Delta y)$, can be formulated as a two-dimensional operation, represented mathematically as:

$$F(x, y) = \sum_{k=-K}^{K-1} \sum_{l=-L}^{L-1} f(k + K, l + L) F(n + k, m + l) \quad (7)$$

where $f(k,l)$ are filter coefficients and n and m are obtained by truncating x and y , respectively, to integer values. Typically, the filter coefficients are dependent on the x and y values and the interpolation filters are usually so-called 'separable filters', in which case sub-pixel value $F(x,y)$ can be calculated as follows:

$$F(x, y) = \sum_{k=-K}^{K-1} f(k + K) \sum_{l=-K}^{K-1} f(l + K) F(n + k, m + l) \quad (8)$$

The motion vectors are calculated in the encoder. Once the corresponding motion coefficients are transmitted to the decoder, it is a straightforward matter to interpolate the required sub-pixels using an interpolation method identical to that used in the encoder. In this way, a frame following a reference frame in the Frame Memory 24, can be reconstructed from the reference frame and the motion vectors.

The simplest way of applying sub-pixel value interpolation in a video coder is to interpolate each sub-pixel value every time it is needed. However, this is not an efficient solution in a video encoder, because it is likely that the same sub-pixel value will be required several times and thus calculations to interpolate the same sub-pixel value will be

performed multiple times. This results in an unnecessary increase of computational complexity/burden in the encoder.

An alternative approach, which limits the complexity of the encoder, is to pre-calculate and store all sub-pixel values in a memory associated with the encoder. This solution is called interpolation 'before-hand' interpolation hereafter in this document. While limiting complexity, before-hand interpolation has the disadvantage of increasing memory usage by a large margin. For example, if the motion vector accuracy is one quarter pixel in both horizontal and vertical dimensions, storing pre-calculated sub-pixel values for a complete image results in a memory usage that is 16 times that required to store the original, non-interpolated image. In addition, it involves the calculation of some sub-pixels which might not actually be required in calculating motion vectors in the encoder. Before-hand interpolation is also particularly inefficient in a video decoder, as the majority of pre-calculated sub-pixel values will never be required by the decoder. Thus, it is advantageous not to use pre-calculation in the decoder.

So-called 'on-demand' interpolation can be used to reduce memory requirements in the encoder. For example, if the desired pixel precision is quarter pixel resolution, only sub-pixels at one half unit resolution are interpolated before-hand for the whole frame and stored in the memory. Values of one-quarter pixel resolution sub-pixels are only calculated during the motion estimation/compensation process as and when it is required. In this case memory usage is only 4 times that required to store the original, non-interpolated image.

It should be noted that when before-hand interpolation is used, the interpolation process constitutes only a small fraction of the total encoder computational complexity/burden, since every pixel is interpolated just once. Therefore, in the encoder, the complexity of the interpolation process itself is not very critical when before-hand sub-pixel value interpolation is used. On the other hand, on-demand interpolation poses a much higher computational burden on the encoder, since sub-pixels may be interpolated many times. Hence the complexity of interpolation process, which may be considered in terms of the number of computational operations or operational cycles that must be performed in order to interpolate the sub-pixel values, becomes an important consideration.

In the decoder, the same sub-pixel values are used a few times at most and some are not needed at all. Therefore, in the decoder it is advantageous not to use before-hand interpolation at all, that is, it is advantageous not to pre-calculate any sub-pixel values.

Two interpolation schemes have been developed as part of the work ongoing in the ITU-Telecommunications Standardization Sector, Study Group 16, Video Coding Experts Group (VCEG), Questions 6 and 15. These approaches were proposed for incorporation into ITU-T recommendation H.26L and have been implemented in test models (TML) for the purposes of evaluation and further development. The test model corresponding to Question 15 is referred to as Test Model 5 (TML5), while that resulting from Question 6 is known as Test Model 6 (TML6). The interpolation schemes proposed in both TML5 and TML6 will now be described.

Throughout the description of the sub-pixel value interpolation scheme used in test model TML5, reference will be made to FIG. 12a, which defines a notation for describing pixel and sub-pixel locations specific to TML5. A separate notation, defined in FIG. 13a, will be used in the discussion of the sub-pixel value interpolation scheme used in TML6. A still further notation, illustrated in FIG. 14a, will be used

later in the text in connection with the sub-pixel value interpolation method according to the invention. It should be appreciated that the three different notations used in the text are intended to assist in the understanding of each interpolation method and to help distinguish differences between them. However, in all three figures, the letter A is used to denote original image pixels (full pixel resolution). More specifically, the letter A represents the location of pixels in the image data representing a frame of a video sequence, the pixel values of pixels A being either received as current frame $I_n(x,y)$ from a video source, or reconstructed and stored as a reference frame $R_n(x,y)$ in the Frame Memory 17, 24 of the encoder 10 or the decoder 20. All other letters represent sub-pixel locations, the values of the sub-pixels situated at the sub-pixel locations being obtained by interpolation.

Certain other terms will also be used in a consistent manner throughout the text to identify particular pixel and sub-pixel locations. These are as follows:

The term 'unit horizontal location' is used to describe the location of any sub-pixel that is constructed in a column of the original image data. Sub-pixels c and e in FIGS. 12a and 13a, as well as sub-pixels b and e in FIG. 14a have unit horizontal locations.

The term 'unit vertical location' is used to describe any sub-pixel that is constructed in a row of the original image data. Sub-pixels b and d in FIGS. 12a and 13a as well as sub-pixels b and d in FIG. 14a have unit vertical locations.

By definition, pixels A have unit horizontal and unit vertical locations.

The term 'half horizontal location' is used to describe the location of any sub-pixel that is constructed in a column that lies at half pixel resolution. Sub-pixels b, c, and e shown in FIGS. 12a and 13a fall into this category, as do sub-pixels b, c and f in FIG. 14a. In a similar manner, the term 'half vertical location' is used to describe the location of any sub-pixel that is constructed in a row that lies at half-pixel resolution, such as sub-pixels c and d in FIGS. 12a and 13a, as well as sub-pixels b, c and g in FIG. 14a.

Furthermore, the term 'quarter horizontal location' refers to any sub-pixel that is constructed in a column which lies at quarter-pixel resolution, such as sub-pixels d and e in FIG. 12a, sub-pixels d and g in FIG. 13a and sub-pixels d, g and h in FIG. 14a. Analogously, the term 'quarter vertical location' refers to sub-pixels that are constructed in a row which lies at quarter-pixel resolution. In FIG. 12a, sub-pixels e and f fall into this category, as do sub-pixels e, f and g in FIG. 13a and sub-pixels e, f and h in FIG. 14a.

The definition of each of the terms described above is shown by 'envelopes' drawn on the corresponding figures.

It should further be noted that it is often convenient to denote a particular pixel with a two-dimensional reference. In this case, the appropriate two-dimensional reference can be obtained by examining the intersection of the envelopes in FIGS. 12a, 13a and 14a. Applying this principle, pixel d in FIG. 12a, for example, has a half horizontal and half vertical location and sub-pixel e has a unit horizontal and quarter vertical location. In addition, and for ease of reference, sub-pixels that reside at half unit horizontal and unit vertical locations, unit horizontal and half unit vertical locations as well as half unit horizontal and half unit vertical locations, will be referred to as $\frac{1}{2}$ resolution sub-pixels. Sub-pixels which reside at any quarter unit horizontal and/or quarter unit vertical location will be referred to as $\frac{1}{4}$ resolution sub-pixels.

It should also be noted that in the descriptions of the two test models and in the detailed description of the invention

itself, it will be assumed that pixels have a minimum value of 0 and a maximum value of 2^n-1 where n is the number of bits reserved for a pixel value. The number of bits is typically 8. After a sub-pixel has been interpolated, if the value of that interpolated sub-pixel exceeds the value of 2^n-1 , it is restricted to the range of $[0, 2^n-1]$, i.e. values lower than the minimum allowed value will become the minimum value (0) and values larger than the maximum will become maximum value (2^n-1). This operation is called clipping.

The sub-pixel value interpolation scheme according to TML5 will now be described in detail with reference to FIGS. 12a, 12b and 12c.

1. The value for the sub-pixel at half unit horizontal and unit vertical location, that is $\frac{1}{2}$ resolution sub-pixel b in FIG. 12a, is calculated using a 6-tap filter. The filter interpolates a value for $\frac{1}{2}$ resolution sub-pixel b based upon the values of the 6 pixels (A_1 to A_6) situated in a row at unit horizontal locations and unit vertical locations symmetrically about b, as shown in FIG. 12b, according to the formula $b=(A_1-5A_2+20A_3+20A_4-5A_5+A_6+16)/32$. The operator/denotes division with truncation. The result is clipped to lie in the range $[0, 2^n-1]$.
2. Values for the $\frac{1}{2}$ resolution sub-pixels labelled c are calculated using the same six tap filter as used in step 1 and the six nearest pixels or sub-pixels (A or b) in the vertical direction. Referring now to FIG. 12c, the filter interpolates a value for the $\frac{1}{2}$ resolution sub-pixel c located at unit horizontal and half vertical location based upon the values of the 6 pixels (A_1 to A_6) situated in a column at unit horizontal locations and unit vertical locations symmetrically about c, according to the formula $c=(A_1-5A_2+20A_3+20A_4-5A_5+A_6+16)/32$. Similarly, a value for the $\frac{1}{2}$ resolution sub-pixel c at half horizontal and half vertical location is calculated according to $c=(b_1-5b_2+20b_3+20b_4-5b_5+b_6+16)/32$. Again, the operator/denotes division with truncation. The values calculated for the c sub-pixels are further clipped to lie in the range $[0, 2^n-1]$.

At this point in the interpolation process the values of all $\frac{1}{2}$ resolution sub-pixels have been calculated and the process proceeds to the calculation of $\frac{1}{4}$ resolution sub-pixel values.

3. Values for the $\frac{1}{4}$ resolution sub-pixels labelled d are calculated using linear interpolation and the values of the nearest pixels and/or $\frac{1}{2}$ resolution sub-pixels in the horizontal direction. More specifically, values for $\frac{1}{4}$ resolution sub-pixels d located at quarter horizontal and unit vertical locations, are calculated by taking the average of the immediately neighbouring pixel at unit horizontal and unit vertical location (pixel A) and the immediately neighbouring $\frac{1}{2}$ resolution sub-pixel at half horizontal and unit vertical location (sub-pixel b), i.e. according to $d=(A+b)/2$. Values for $\frac{1}{4}$ resolution sub-pixels d located at quarter horizontal and half vertical locations, are calculated by taking the average of the immediately neighbouring $\frac{1}{2}$ resolution sub-pixels c which lie at unit horizontal and half vertical location and half horizontal and half vertical locations respectively, i.e. according to $d=(c_1+c_2)/2$. Again operator/indicates division with truncation.
4. Values for the $\frac{1}{4}$ resolution sub-pixels labelled e are calculated using linear interpolation and the values of the nearest pixels and/or $\frac{1}{2}$ resolution sub-pixels in the vertical direction. In particular, $\frac{1}{4}$ resolution sub-pixels e at unit horizontal and quarter vertical locations are

11

calculated by taking the average of the immediately neighbouring pixel at unit horizontal and unit vertical location (pixel A) and the immediately neighbouring sub-pixel at unit horizontal and half vertical location (sub-pixel c) according to $e=(A+c)/2$. $1/4$ resolution sub-pixels e_3 at half horizontal and quarter vertical locations are calculated by taking the average of the immediately neighbouring sub-pixel at half horizontal and unit vertical location (sub-pixel b) and the immediately neighbouring sub-pixel at half horizontal and half vertical location (sub-pixel c), according to $e=(b+c)/2$. Furthermore, $1/4$ resolution sub-pixels e at quarter horizontal and quarter vertical locations are calculated by taking the average of the immediately neighbouring sub-pixels at quarter horizontal and unit vertical location and the corresponding sub-pixel at quarter horizontal and half vertical location (sub-pixels d), according to $e=(d_1+d_2)/2$. Once more, operator/indicates division with truncation.

- 5 The value for $1/4$ resolution sub-pixel f is interpolated by averaging the values of the 4 closest pixels values at unit horizontal and vertical locations, according to $f=(A_1+A_2+A_3+A_4+2)/4$, where pixels A_1 , A_2 , A_3 and A_4 are the four nearest original pixels.

A disadvantage of TML5 is that the decoder is computationally complex. This results from the fact that TML5 uses an approach in which interpolation of $1/4$ resolution sub-pixel values depends upon the interpolation of $1/2$ resolution sub-pixel values. This means that in order to interpolate the values of the $1/4$ resolution sub-pixels, the values of the $1/2$ resolution sub-pixels from which they are determined must be calculated first. Furthermore, since the values of some of the $1/4$ resolution sub-pixels depend upon the interpolated values obtained for other $1/4$ resolution sub-pixels, truncation of the $1/4$ resolution sub-pixel values has a deleterious effect on the precision of some of the $1/4$ resolution sub-pixel values. Specifically, the $1/4$ resolution sub-pixel values are less precise than they would be if calculated from values that had not been truncated and clipped. Another disadvantage of TML5 is that it is necessary to store the values of the $1/2$ resolution sub-pixels in order to interpolate the $1/4$ resolution sub-pixel values. Therefore, excess memory is required to store a result which is not ultimately required.

The sub-pixel value interpolation scheme according to TML6, referred to herein as direct interpolation, will now be described. In the encoder the interpolation method according to TML6 works like the previously described TML5 interpolation method, except that maximum precision is retained throughout. This is achieved by using intermediate values which are neither rounded nor clipped. A step-by-step description of interpolation method according to TML6 as applied in the encoder is given below with reference to FIGS. 13a, 13b and 13c.

1. The value for the sub-pixel at half unit horizontal and unit vertical location, that is $1/2$ resolution sub-pixel b in FIG. 13a, is obtained by first calculating an intermediate value b using a six tap filter. The filter calculates b based upon the values of the 6 pixels (A_1 to A_6) situated in a row at unit horizontal locations and unit vertical locations symmetrically about b, as shown in FIG. 13b, according to the formula $b=(A_1-5A_2+20A_3+20A_4-5A_5+A_6)$. The final value of b is then calculated as $b=(b+16)/32$ and is clipped to lie in the range $[0, 2^n-1]$. As before, the operator/denotes division with truncation.
2. Values for the $1/2$ resolution sub-pixels labelled c are obtained by first: calculating intermediate values c.

12

Referring to FIG. 13c, an intermediate value c for the $1/2$ resolution sub-pixel c located at unit horizontal and half vertical location is calculated based upon the values of the 6 pixels (A_1 to A_6) situated in a column at unit horizontal locations and unit vertical locations symmetrically about c, according to the formula $c=(A_1-5A_2+20A_3+20A_4-5A_5+A_6)$. The final value for the $1/2$ resolution sub-pixel c located at unit horizontal and half vertical location is then calculated according to $c=(c+16)/32$. Similarly, an intermediate value c for the $1/2$ resolution sub-pixel c at half horizontal and half vertical location is calculated according to $c=(b_1-5b_2+20b_3+20b_4-5b_5+b_6)$. A final value for this $1/2$ resolution sub-pixel is then calculated according to $(c+512)/1024$. Again, the operator/denotes division with truncation and the values calculated for $1/2$ resolution sub-pixels c are further clipped to lie in the range $[0, 2^n-1]$.

3. Values for the $1/4$ resolution sub-pixels labelled d are calculated as follows. Values for $1/4$ resolution sub-pixels d located at quarter horizontal and unit vertical locations, are calculated from the value of the immediately neighbouring pixel at unit horizontal and unit vertical location (pixel A) and the intermediate value b calculated in step (1) for the immediately neighbouring $1/2$ resolution sub-pixel at half horizontal and unit vertical location ($1/2$ resolution sub-pixel b), according to $d=(32A+b+32)/64$. Values for $1/4$ resolution sub-pixels d located at quarter horizontal and half vertical locations, are interpolated using the intermediate values c calculated for the immediately neighbouring $1/2$ resolution sub-pixels c which lie at unit horizontal and half vertical location and half horizontal and half vertical locations respectively, according to $d=(32c_1+c_2+1024)/2048$. Again operator/indicates division with truncation and the finally obtained $1/4$ resolution sub-pixel values d are clipped to lie in the range $[0, 2^n-1]$.
4. Values for the $1/4$ resolution sub-pixels labelled e are calculated as follows. Values for $1/4$ resolution sub-pixels e located at unit horizontal and quarter vertical locations are calculated from the value of the immediately neighbouring pixel at unit horizontal and unit vertical location (pixel A) and the intermediate value c calculated in step (2) for the immediately neighbouring $1/2$ resolution sub-pixel at unit horizontal and half vertical location, according to $e=(32A+c+32)/64$. Values for $1/4$ resolution sub-pixels e located at half horizontal and quarter vertical locations are calculated from the intermediate value b calculated in step (1) for the immediately neighbouring $1/2$ resolution sub-pixel at half horizontal and unit vertical location and the intermediate value c calculated in step (2) for the immediately neighbouring $1/2$ resolution sub-pixel at half horizontal and half vertical location, according to $e=(32b+c+1024)/2048$. Once more, operator/indicates division with truncation and the finally obtained $1/4$ resolution sub-pixel values e are clipped to lie in the range $[0, 2^n-1]$.
5. Values for $1/2$ resolution sub-pixels labelled g are computed using the value of the nearest original pixel A and the intermediate values of the three nearest neighbouring $1/2$ resolution sub-pixels, according to $g=(1024A+32b+32c_1+c_2+2048)/4096$. As before, operator/indicates division with truncation and the finally obtained for $1/4$ resolution sub-pixel values g are clipped to lie in the range $[0, 2^n-1]$.
6. The value for $1/4$ resolution sub-pixel f is interpolated by averaging the values of the 4 closest pixels at unit

13

horizontal and vertical locations, according to $f=(A_1+A_2+A_3+A_4)/4$, where the locations of pixels A_1 , A_2 , A_3 , and A_4 are the four nearest original pixels.

In the decoder, sub-pixel values can be obtained directly by applying 6-tap filters in horizontal and vertical directions. In the case of $1/4$ sub-pixel resolution, referring to FIG. 13a, the filter coefficients applied to pixels and sub-pixels at unit vertical location are $[0, 0, 64, 0, 0, 0]$ for a set of six pixels A , $[1, -5, 52, 20, -5, 1]$ for a set of six sub-pixels d , $[2, -10, 40, 40, -10, 2]$ for a set of six sub-pixels b , and $[1, -5, 20, 52, -5, 1]$ for a set of six sub-pixels c . These filter coefficients are applied to respective sets of pixels or sub-pixels in the same row as the sub-pixel values being interpolated.

After applying the filters in the horizontal and vertical directions, interpolated value c is normalized according to $c=(c+2048)/4096$ and clipped to lie in the range $[0, 2^n-1]$. When a motion vector points to an integer pixel position in either the horizontal or vertical direction, many zero coefficients are used. In a practical implementation of TML6, different branches are used in the software which are optimised for the different sub-pixel cases so that there are no multiplications by zero coefficients.

It should be noted that in TML6, $1/4$ resolution sub-pixel values are obtained directly using the intermediate values referred to above and are not derived from rounded and clipped values for $1/2$ resolution sub-pixels. Therefore, in obtaining the $1/4$ resolution sub-pixel values, it is not necessary to calculate final values for any of the $1/2$ resolution sub-pixels. Specifically, it is not necessary to carry out the truncation and clipping operations associated with the calculation of final values for the $1/2$ resolution sub-pixels. Neither is it necessary to have stored final values for $1/2$ resolution sub-pixels for use in the calculation of the $1/4$ resolution sub-pixel values. Therefore TML6 is computationally less complex than TML5, as fewer truncating and clipping operations are required. However, a disadvantage of TML6 is that high precision arithmetic is required both in the encoder and in the decoder. High precision interpolation requires more silicon area in ASICs and requires more computations in some CPUs. Furthermore, implementation of direct interpolation as specified in TML6 in an on-demand fashion has a high memory requirement. This is an important factor, particularly in embedded devices.

In view of the previously presented discussion, it should be appreciated that due to the different requirements of the video encoder and decoder with regard to sub-pixel interpolation, there exists a significant problem in developing a method of sub-pixel value interpolation capable of providing satisfactory performance in both the encoder and decoder. Furthermore, neither of the current test models (TML5, TML6) described in the foregoing can provide a solution that is optimum for application in both encoder and decoder.

SUMMARY OF THE INVENTION

According to a first aspect of the invention there is provided method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $1/2^x$, where x is a positive integer having a maximum value N , the method comprising:

14

- a) when values for sub-pixels at $1/2^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $1/2^{N-1}$ unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) when values for sub-pixels at $1/2^{N-1}$ unit horizontal and $1/2^{N-1}$ unit vertical locations are required, interpolating such values directly using a choice of a first weighted sum of values for sub-pixels residing at $1/2^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $1/2^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and
- c) when a value for a sub-pixel situated at a $1/2^N$ unit horizontal and $1/2^N$ unit vertical location is required, interpolating such a value by taking a weighted average of the value of a first sub-pixel or pixel situated at a $1/2^{N-m}$ unit horizontal and $1/2^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $1/2^{N-p}$ unit horizontal and $1/2^{N-q}$ unit vertical location, variables m , n , p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $1/2^N$ unit horizontal and $1/2^N$ unit vertical location.

Preferably a first and a second weight are used in the weighted average referred to in (c), the relative magnitudes of the weights being inversely proportional to the (straight-line diagonal) proximity of the first and the second sub-pixel or pixel to the sub-pixel at $1/2^N$ unit horizontal and $1/2^N$ unit vertical location.

In a situation where the first and the second sub-pixel or pixel are symmetrically located with respect to (equidistant from) the sub-pixel at $1/2^N$ unit horizontal and $1/2^N$ unit vertical location, the first and second weights may have equal values.

The first weighted sum of values for sub-pixels residing at $1/2^{N-1}$ unit horizontal and unit vertical locations in step b) may be used when a sub-pixel at $1/2^{N-1}$ unit horizontal and $1/2^{N-1}$ unit vertical location is required.

The second weighted sum of values for sub-pixels residing at unit horizontal and $1/2^{N-1}$ unit vertical locations in step b) may be used when a sub-pixel at $1/2^N$ unit horizontal and $1/2^{N-1}$ unit vertical location is required.

In one embodiment, when values for sub-pixels at $1/2^N$ unit horizontal and unit vertical locations, and $1/2^N$ unit horizontal and $1/2^{N-1}$ unit vertical locations are required, such values are interpolated by taking the average of the values of a first pixel or sub-pixel located at a vertical location corresponding to that of the sub-pixel being calculated and unit horizontal location and a second pixel or sub-pixel located at a vertical location corresponding to that of the sub-pixel being calculated and $1/2^{N-1}$ unit horizontal location.

When values for sub-pixels at unit horizontal and $1/2^N$ unit vertical locations, and $1/2^{N-1}$ unit horizontal and $1/2^N$ unit vertical locations are required, they may be interpolated by taking the average of the values of a first pixel or sub-pixel located at a horizontal location corresponding to that of the sub-pixel being calculated and unit vertical location and a second pixel or sub-pixel located at a horizontal location corresponding to that of the sub-pixel being calculated and $1/2^{N-1}$ unit vertical location.

Values for sub-pixels at $1/2^N$ unit horizontal and $1/2^N$ unit vertical locations may be interpolated by taking the average of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $1/2^{N-1}$ unit horizontal and $1/2^{N-1}$ unit vertical location.

Values for sub-pixels at $1/2^N$ unit horizontal and $1/2^N$ unit vertical locations may be interpolated by taking the average

15

of values of a sub-pixel located at a $1/2^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $1/2^{N-1}$ unit vertical location.

Values for half of the sub-pixels at $1/2^N$ unit horizontal and $1/2^N$ unit vertical locations may be interpolated by taking the average of a first pair of values of a sub-pixel located at a $1/2^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $1/2^{N-1}$ unit vertical location and values for the other half of the sub-pixels at $1/2^N$ unit horizontal and $1/2^N$ unit vertical locations are interpolated by taking the average of a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $1/2^{N-1}$ unit horizontal and $1/2^{N-1}$ unit vertical location.

Values for sub-pixels at $1/2^N$ unit horizontal and $1/2^N$ unit vertical locations are alternately interpolated for one such sub-pixel by taking the average of a first pair of values of a sub-pixel located at a $1/2^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $1/2^{N-1}$ unit vertical location and values and for a neighbouring such sub-pixel by taking the average of a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $1/2^{N-1}$ unit horizontal and $1/2^{N-1}$ unit vertical location.

The sub-pixels at $1/2^N$ unit horizontal and $1/2^N$ unit vertical locations may be alternately interpolated in a horizontal direction.

The sub-pixels at $1/2^N$ unit horizontal and $1/2^N$ unit vertical locations may be alternately interpolated in a horizontal direction.

When values for some sub-pixels at $1/2^N$ unit horizontal and $1/2^N$ unit vertical locations are required, such values may be interpolated by taking the average of a plurality of nearest neighbouring pixels.

At least one of step a) and step b) interpolating sub-pixel values directly using weighted sums may involve the calculation of an intermediate value for the sub-pixel values having a dynamic range greater than the specified dynamic range.

The intermediate value for a sub-pixel having $1/2^{N-1}$ sub-pixel resolution may be used the calculation of a sub-pixel value having $1/2^N$ sub-pixel resolution.

According to a second aspect of the invention, there is provided a method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the method comprising:

- a) when values for sub-pixels at half unit horizontal and unit vertical locations, and unit horizontal and half unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) when values for sub-pixels at half unit horizontal and half unit vertical locations are required, interpolating such values directly using a weighted sum of values for sub-pixels residing at half unit horizontal and unit vertical locations calculated according to step (a); and
- c) when values for sub-pixels at quarter unit horizontal and quarter unit vertical locations are required, interpolating such values by taking the average of at least one pair of a first pair of values of a sub-pixel located at a half unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and half unit vertical location

16

and a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a half unit horizontal and half unit vertical location.

According to a third aspect of the invention, there is provided a method of interpolation in video coding in which an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, is interpolated to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $1/2^x$ where x is a positive integer having a maximum value N, the method comprising:

- a) when values for sub-pixels at $1/2^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $1/2^{N-1}$ unit vertical locations are required, interpolating such values directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) when a value for a sub-pixel at a sub-pixel horizontal and sub-pixel vertical location is required, interpolating such a value directly using a choice of a first weighted sum of values for sub-pixels located at a vertical location corresponding to that of the sub-pixel being calculated and a second weighted sum of values for sub-pixels located at a horizontal location corresponding to that of the sub-pixel being calculated.

The sub-pixels used in the first weighted sum may be sub-pixels residing at $1/2^{N-1}$ unit horizontal and unit vertical locations and the first weighted sum may be used to interpolate a value for a sub-pixel at $1/2^{N-1}$ unit horizontal and $1/2^N$ unit vertical location.

The sub-pixels used in the second weighted sum may be sub-pixels residing at unit horizontal and $1/2^{N-1}$ unit vertical locations and the second weighted sum may be used to interpolate a value for a sub-pixel at $1/2^N$ unit horizontal and $1/2^{N-1}$ unit vertical location.

When values for sub-pixels at $1/2^N$ unit horizontal and $1/2^N$ unit vertical locations are required, they may be interpolated by taking the average of at least one pair of a first pair of values of a sub-pixel located at a $1/2^{N-1}$ unit horizontal and unit vertical location, and a sub-pixel located at a unit horizontal and $1/2^{N-1}$ unit vertical location and a second pair of values of a pixel located at a unit horizontal and unit vertical location, and a sub-pixel located at a $1/2^{N-1}$ unit horizontal and $1/2^{N-1}$ unit vertical location.

In the foregoing, N may be equal an integer selected from a list consisting of the values 2, 3, and 4.

Sub-pixels at quarter unit horizontal location are to be interpreted as being sub-pixels having as their left-hand nearest neighbour a pixel at unit horizontal location and as their right-hand nearest neighbour a sub-pixel at half unit horizontal location as well as sub-pixels having as their left-hand nearest neighbour a sub-pixel at half unit horizontal location and as their right-hand nearest neighbour a pixel at unit horizontal location. Correspondingly, sub-pixels at quarter unit vertical location are to be interpreted as being sub-pixels having as their upper nearest neighbour a pixel at unit vertical location and as their lower nearest neighbour a sub-pixel at half unit vertical location as well as sub-pixels having as their upper nearest neighbour a sub-pixel at half unit vertical location and as their lower nearest neighbour a pixel at unit vertical location.

The term dynamic range, refers to the range of values which the sub-pixel values and the weighted sums can take.

Preferably changing the dynamic range, whether by extending it or reducing it, means changing the number of bits which are used to represent the dynamic range.

In an embodiment of the invention, the method is applied to an image that is sub-divided into a number of image blocks. Preferably each image block comprises four corners, each corner being defined by a pixel located at a unit horizontal and unit vertical location. Preferably the method is applied to each image block as the block becomes available for sub-pixel value interpolation. Alternatively, sub-pixel value interpolation according to the method of the invention is performed once all image blocks of an image have become available for sub-pixel value interpolation.

Preferably the method is used in video encoding. Preferably the method is used in video decoding.

In one embodiment of the invention, when used in encoding, the method is carried out as before-hand interpolation, in which values for all sub-pixels at half unit locations and values for all sub-pixels at quarter unit locations are calculated and stored before being subsequently used in the determination of a prediction frame during motion predictive coding. In alternative embodiments, the method is carried out as a combination of before-hand and on-demand interpolation. In this case, a certain proportion or category of sub-pixel values is calculated and stored before being used in the determination of a prediction frame and certain other sub-pixel values are calculated only when required during motion predictive coding.

Preferably, when the method is used in decoding, sub-pixels are only interpolated when their need is indicated by a motion vector.

According to a fourth aspect of the invention, there is provided a video coder for coding an image comprising pixels arranged in rows and columns and represented by values having a specified dynamic range, the pixels in the rows residing at unit horizontal locations and the pixels in the columns residing at unit vertical locations, the video coder comprising an interpolator adapted to generate values for sub-pixels at fractional horizontal and vertical locations, the fractional horizontal and vertical locations being defined according to $1/2^x$, where x is a positive integer having a maximum value N , the interpolator being adapted to:

- a) interpolate values for sub-pixels at $1/2^{N-1}$ unit horizontal and unit vertical locations, and unit horizontal and $1/2^{N-1}$ unit vertical locations directly using weighted sums of pixels residing at unit horizontal and unit vertical locations;
- b) interpolate values for sub-pixels at $1/2^{N-1}$ unit horizontal and $1/2^{N-1}$ unit vertical locations directly using a choice of a first weighted sum of values for sub-pixels residing at $1/2^{N-1}$ unit horizontal and unit vertical locations and a second weighted sum of values for sub-pixels residing at unit horizontal and $1/2^{N-1}$ unit vertical locations, the first and second weighted sums of values being calculated according to step (a); and
- c) interpolate a value for a sub-pixel situated at a $1/2^N$ unit horizontal and $1/2^N$ unit vertical location by taking a weighted average of the value of a first sub-pixel or pixel situated at a $1/2^{N-m}$ unit horizontal and $1/2^{N-n}$ unit vertical location and the value of a second sub-pixel or pixel located at a $1/2^{N-p}$ unit horizontal and $1/2^{N-q}$ unit vertical location, variables m , n , p and q taking integer values in the range 1 to N such that the first and second sub-pixels or pixels are located diagonally with respect to the sub-pixel at $1/2^N$ unit horizontal and $1/2^N$ vertical location.
